This Is An Ad-Reading Age

The Weekly Ad-Talk Page

¶ People in every walk of life, today, read ads. ¶ They read them because the ads of today are universally interesting, because they are informative. ¶ Because the ads not only enable the buyer to buy wisely but very frequently teach what one wants and needs to buy. ¶ They read the ads because they know that advertised goods, equipment, supplies or what not are *good* goods—equipment or supplies—if they were not they could not be advertised continuously. ¶ They *find pleasure* in reading the ads of this wide-awake, stirring commerical age; they *learn* by reading the ads; they *save money*. ¶ *Cultivate the ad-reading and ad-buying habit—it's a good one!*

COAL AGE

Vol. 5 NEW YORK, MARCH 7, 1914 No. 10

MOST every mine superintendent decorates his office walls with mottoes. We use the word "decorate" advisedly; in fact, we believe that we might have used a more sarcastic term without giving offence.

Occasionally though, we bump into a motto that does not seem to be a part of the furniture, but belongs rather, to the atmosphere of the office.

Such a one adorns the wall immediately facing the incoming visitor, at the office of a Scotch friend of ours:— "Let men know that they are men; created by God, responsible to God; who work in any meanest moment of time what will last throughout eternity." "That's fine," we said, "Where did you discover it?" Our Scotch friend looked at us pityingly, "Discover it! why man that is *the* message that John Knox gave to mankind."

We have since had revealed to us by an essay of Carlyle's that our friend knew what he was talking about. Scotchmen generally do.

But to return to the motto: Since *we* discovered it, the real meaning of the thought has constantly grown on us and whenever we run across "safety first" literature, the idea occurs to us that possibly nothing has been published equal to this motto, as a reminder to man of man's responsibility for his every act.

For example: A miner carelessly wanders around with an open light, in a room known to contain gas. An explosion results and several lives are snuffed out. Perhaps the victims had never thought seriously of death or of a world to come. Surley, to quote the motto, in a meanest moment of time their lives have been effected for all eternity. Pretty serious business, that; when you come to consider it from such a view-point, be ye atheist, deist, or theist.

And how about the widow and the orphans. Yesterday a happy, complete family; to-day sorrowing; to-morrow separated by the ends of the earth; father dead, mother here, childern there. Changed are their lives for all eternity, and yet the carless one who wandered around down in the pit, whistling as he went, never so much as gave *them* a thought.

Throughout eternity is a pretty long time: so long, in fact, that any fellow who is willing to tempt fate by going contrary to "safety first" rules, might well hesitate long enough to take a second think before starting into action.

Some French and German Electric Hoists

Special Correspondence

SYNOPSIS—Some recent installations for deep shafts are here described. The hoists are all fitted with direct-current motors, but the sources of supply are plain and flywheel motor-generator sets or low-pressure turbo units, operating on exhaust steam.

The application of electric power to hoisting coal and the handling of men and material has received much attention in Europe during the past few years. This is particularly true in France and Germany. As a result there are now to be found in the coal-mining regions some good examples of hoisting engines, the principal features of which will be here briefly summarized.

We are indebted for the data to the Societe Alsacienne de Constructions Mecaniques, of Belfort, which has for several years made a specialty of electrically operated hoists in connection with converter sets both with and without flywheels. Among the most interesting of these installations may be mentioned those at Bethune, Courrieres, Kali-Sainte-Therese, and Carmaux.

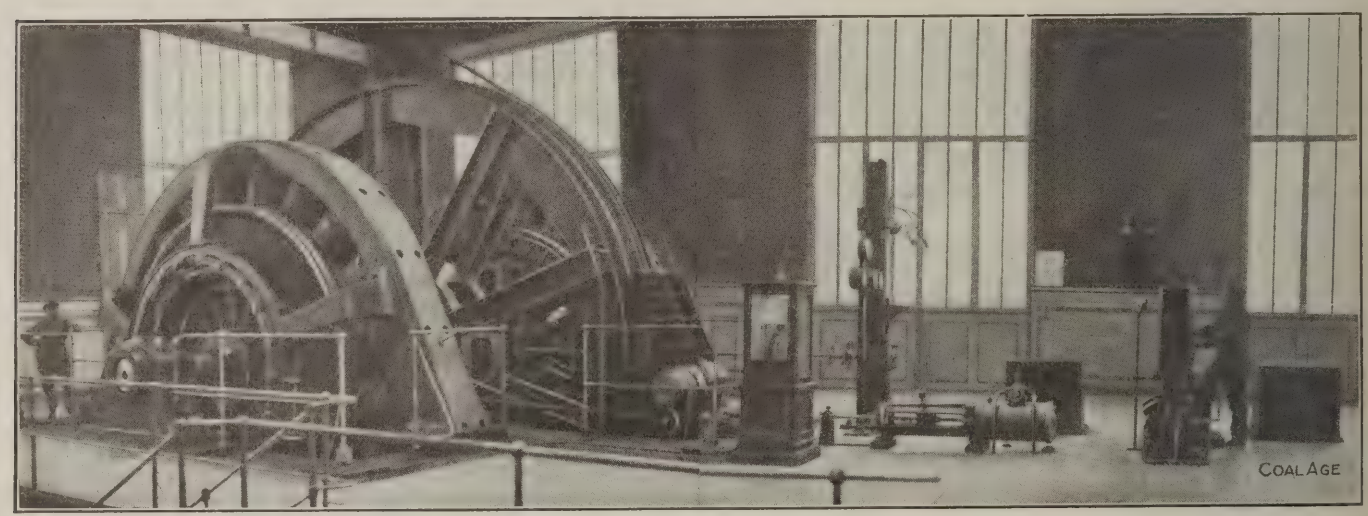

Fig. 1. Hoist Installed at the Bethune Mines

Two Sets of Conditions Must Be Met

The hoist at the Bethune mines (see Fig. 1) has been built to cope with a double set of requirements. The first is to hoist 235 metric tons (approximately 240 American tons) per hour from a depth of 430 m. (1420 ft.) in 50 hoists, while the second is to handle 265 metric tons (approximately 270 American tons) from a depth of 530 m. (1780 ft.) in 38 hoists. The machine is provided with a Koepe pulley 7 m. (23 ft.) in diameter with a balancing rope.

At each end of the Koepe pulley shaft, there is a continuous-current motor operating at a maximum speed of 32.7 r.p.m. for the 430-meter stage and at 29.5 r.p.m. for the 530-meter level. The supply voltage to these motors varies from 0 to approximately 500 volts. The current is furnished by the generators of two converter sets provided with a flywheel turning at a speed varying between 485 r.p.m. and 410 r.p.m. Each set consists of a continuous-current generator operating at 500 volts in either direction with commutating poles and an asynchronous three-phase motor drawing its current from a 5000-volt 50-cycle system of supply, and capable of developing as a normal load 400 hp.

There is also a flywheel consisting of a single steel casting weighing 22 metric tons (approximately 22.4 American tons), the peripheral speed of which is 85 m. (278 ft.) per second. This is capable of storing energy to the extent of 5,000,000 kgm. (36,800,000 ft.-lb.).

Normal hoisting is accomplished by placing the two motors in series, these being fed by the two generators also operating in series. In case of damage to one of the machines, it is possible by a single converter set and the two motors to raise the full load at half speed, or with a single set and single motor half load at half speed can be negotiated. In this way, even supposing that a motor and converter set were both put out of business, operation would not be completely interrupted.

Exhaust Steam Furnishes Hoisting Energy

The hoisting installation at the Courrieres mine is particularly interesting since it utilizes as its source of energy the exhaust steam from several engines. The electric motors of the two converter sets are here replaced by low-pressure steam turbines. Each set comprises a turbine and two generators with independent excitation.

Between the two groups which are placed end to end as shown in Fig. 2, there is a flywheel which can be coupled to either of the sets by means of a clutch. The set connected with the flywheel operates the hoist motor only. It runs at a normal speed of 1500 r.p.m., and a drop in speed of 25% allows the stored energy of the flywheel to be used.

The other set runs independently of the first at a speed of 1500 r.p.m. and furnishes continuous current at 500 volts to various motors about the plant.

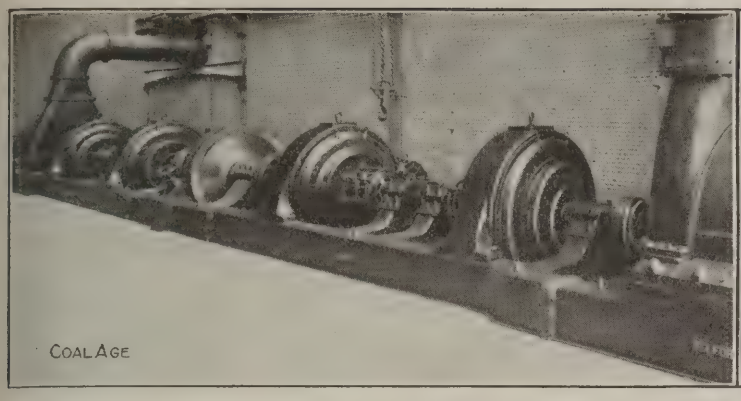

FIG. 2. TURBINE-DRIVEN GENERATORS PROVIDED WITH A FLYWHEEL

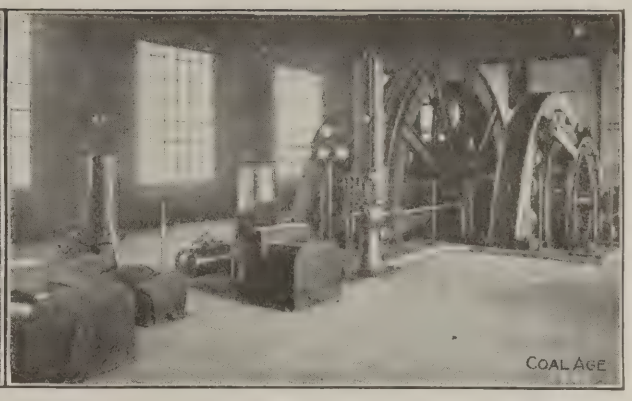

FIG. 3. A TWO-MOTOR HOIST WITH A KOEPE PULLEY

A simple modification of the connection effected by section and change-over switches allows the feeding of the hoist motors by the second group, which then operates under the same conditions as the first. The electric motors, which are ordinarily supplied with current by this group, are then replaced practically immediately by the old steam-engine equipments which were displaced.

The turbines shown in Fig. 2 operate on the Zoelly system, the pressure at the admission valve being 1.15 kg. per sq.cm. (about 16.4 lb. per sq.in.). The centrifugal governor operates by throttling and allows the running to be effected either at a constant speed of 1500 r.p.m., or at a speed variable between the limits of 1500 and 1125 revolutions per minute.

The generators which for hoisting are connected in series, give a potential of approximately 500 volts. They are furnished with auxiliary poles and their commutators are strengthened by hoops or bands to resist the high peripheral speed. Excitation of both generators and motors is furnished during normal operations by an exciter, belt-driven from the set operating at constant speed. When, however, the hoist operates with the second converter-set the exciter is driven by a vertical high-speed steam engine.

The converter flywheel is of forged nickel steel weighing about 8½ metric tons (approximately 8.64 American tons), while its peripheral speed attains 130 meters (427 ft.) per second. This is capable of storing 3,500,000 kgm. (25,300,000 ft.-lb.) of energy.

The hoisting engine shown in Fig. 3 is provided with a Koepe pulley 6½ m. (21.4 ft.) in diameter. It is capable of hoisting 200 metric tons (203 American tons) per hour from a depth of 400 m. (1330 ft.) in 48 hoists. The two continuous-current motors driving it, operate at a potential varying between zero and approximately 500 volts and turn at a maximum speed of 35 r.p.m. One motor is placed upon either side of the Koepe pulley.

HOISTS AT POTASH MINES

Mention might also be made of the four electric hoists installed at the Kalibergwerke, which are important potash mines in the Alsace territory. These machines, one of which is illustrated in Fig. 4, are of the Koepe pulley type, the pulleys being 5 m. (16.4 ft.) in diameter, running at a speed of 42 r.p.m. The rate of hoisting required is 90 metric tons (91½ American tons) per hour from a depth of 750 m. (2460 ft.) in 30 hoists, or 80 metric tons (81.3 American tons) from 900 m. (2965 ft.) in 70 hoists.

Two of these machines are used for sinking and for this purpose are furnished at one side or other of the Koepe pulley with special drums for use in this work. The motors of these machines are fed by a Leonard converter set without flywheel of the type shown in Fig. 5. This method of operation is economical since the supply system is sufficiently large to withstand without ill effects the variation of load due to the hoisting engines.

DRUM HOISTS TAKING A FLAT ROPE

The Societe Alsacienne has installed four electrical hoisting engines at the mines La Grillatie and La Tronquie in the Carmaux district. These two installations are practically identical, so that only one requires a description.

The two machines included in the installation are re-

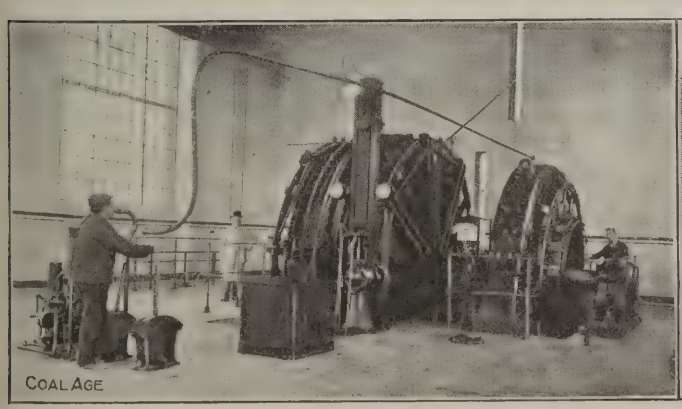

FIG. 4. A HOIST AT A POTASH MINE

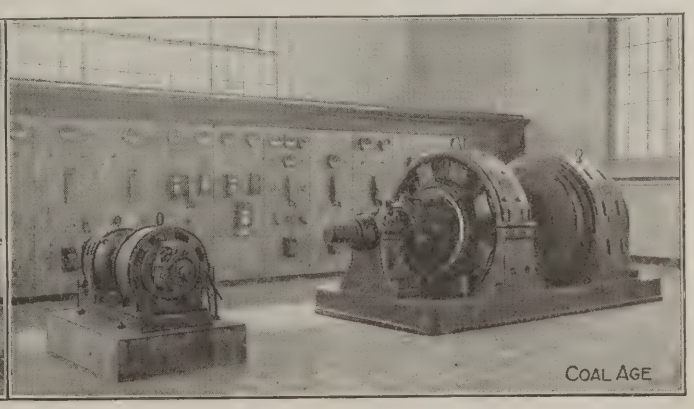

FIG. 5. A LEONARD CONVERTER SET

quired to extract 120 metric tons (122 American tons) per hour from a depth of about 440 m. (1446 ft.) in 43 hoists, the net load dealt with being 2820 kg. (6220 lb.). They are of the drum type, as shown in Fig. 6. A flat steel rope is employed having a section decreasing from 310x50 mm. (approximately $12\frac{1}{4}$x$1\frac{15}{16}$ in.) to 230x40 mm. (9x$1\frac{9}{16}$ in.) The drive for each machine consists of two electric motors capable of running together or separately, which are fed by a converter set (see Fig. 7) composed of two direct-current generators furnishing a 500-volt supply from an asynchronous three-phase motor of 480-hp., running at 585 r.p.m.

The converters of both engines are coupled mechanically to the same flywheel and the generators are also held in step electrically. This allows the uniting of the stored energy of the turning masses of the two converters for the purpose of smoothing out the variations of load produced by the combined action of the two hoisting engines.

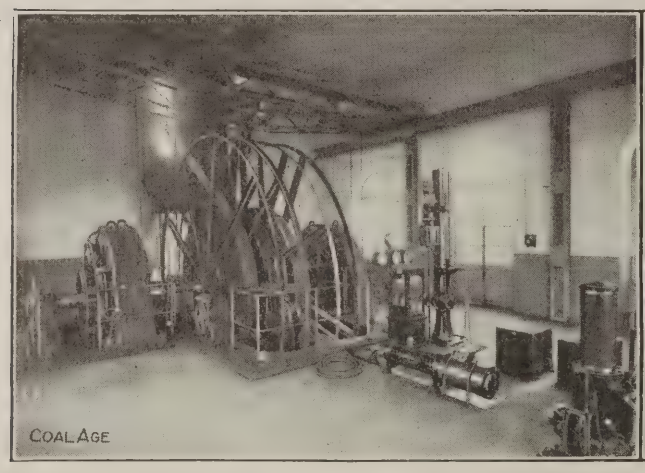

FIG 6. A DRUM-TYPE HOIST USING A FLAT ROPE

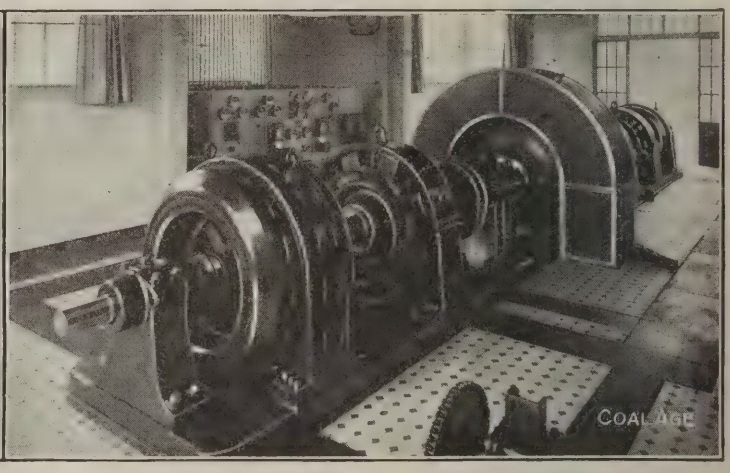

FIG. 7. MOTOR-GENERATOR SETS FEEDING HOIST SHOWN IN FIG. 6.

These examples well illustrate the lines upon which the installation of electricity for hoisting from deep and medium depth shafts is being dealt with in an important European coal area. The types of machines are, of course, divergent depending on the requirements of the work to be done in each particular case. The complete applicability of electric power and the value of the rotary converter are, however, points well worth noting.

Notification to Operators and Miners

Reckless miners and mine foremen who risk their own lives and the lives of other men working in the mines are to be punished to the fullest extent of the law hereafter. This announcement has been made by the State Mining Department of West Virginia in a circular letter to the various district inspectors.

Each of the twelve district inspectors of the state has received the letter from Chief Inspector Henry, containing his specific and unmistakable instructions that whenever a man is found persisting in dangerous practices he is to be summarily dealt with. The letter of Chief Inspector Henry to the district inspectors is as follows:

By referring to Section 15 of the mining laws you will notice that the mine foreman is in absolute charge of all underground conditions and it is his duty to see that the mining laws are strictly complied with, and, in the future, where you find it necessary to prosecute miners or mine laborers for persisting in any dangerous practices that would create accidents or destruction of property, you will prosecute the mine foremen also for permitting any violation of the mining laws and rules of the companies. In your future inspections you should warn all foremen in regard to the above instructions.

In addition to this letter, Chief Henry has also written to the operators of the state, notifying them that the inspectors will prosecute mine foremen and miners hereafter for violation of the state laws and the company's rules for the conduct of the men underground.

Mr. Henry said recently that it had been necessary lately to prosecute miners for shooting off the solid and he said that it had been proven in each instance that the men had done this in the face of direct and specific instructions from mine foremen to the contrary. He also called attention to the fact that miners persisted in riding on trips and that that was a direct violation of the state mining laws.

He added that if the state officials could not induce the miners to have regard for their own lives and the lives of others by showing them what was right, the officials would see that every man violating the law was punished. He added that after a few men had been heavily fined it would not be necessary afterward to tell them or their comrades more than once to do or not to do a given thing that would insure safety.

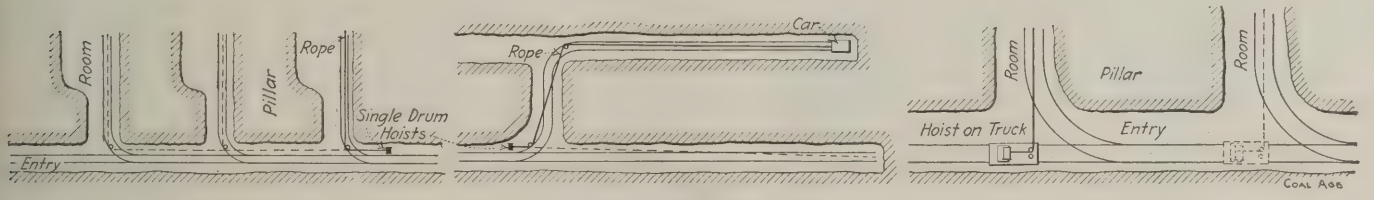
WHY APPLY LAW ONLY TO MINERS AND FOREMEN?

We are glad to see that Mr. Henry so clearly understands his duties and we hope he will show equal energy in shutting down mines, and obtaining convictions of operators and superintendents where second openings are not provided, where the bratticing is defective or the air current insufficient. We would not be displeased to see some few unruly miners and foremen fined, but we would like to arrange that they might have some distinguished company.

As the legal responsibility of the mine foreman is more easily proved than that of his employer or the superintendent, Mr. Henry writes to the operators, doubtless hoping that they will provide the needed funds for improving their mines, so that it will not be necessary for their mine foremen to serve jail sentences or resign their positions. We trust they will take that gentle hint.

Some New Types of Electric Hoists

SYNOPSIS—A description of two new machines for use in replacing single cars in coal mines where the grades are too steep to admit of their being successfully moved by man-power.



In practically every coal mine there are some working places driven upon such grades that mine cars cannot be readily handled by the miner and his helper. In such cases it becomes necessary to remove the cars by some force other than man-power.

Mules or gathering locomotives are sometimes applicable to this work, but in many instances the most satisfactory system is one whereby the miner handles his own cars by means of a small semi-portable hoist. He is thus able to work at his best efficiency while at the same time the haulage locomotives can be utilized to their utmost extent, as they are relieved of the work of gathering.

To meet the demands for machines suitable for this work, two small electric hoists have been recently placed upon the market by the Pneumelectric Machine Co., of Syracuse, N. Y. These machines were developed after a careful study of the conditions to be met. They are designated by the manufacturer as the Room Hoist, and the electric Cap-Stan, respectively, and are shown in Figs. 4 and 7. Both machines have been designed for the purpose of handling one or two cars, loaded or empty, on grades such as prevail in coal mines.

The particular uses to which each machine is adapted will be brought out briefly in the following paragraphs. Both machines are extremely simple and rugged in construction, and the ordinary miner is abundantly capable of operating either to the best advantage.

The Room Hoist shown in Fig. 4 is a complete hoisting machine equipped with a suitable motor and controlling device, clutch, brake, etc. It is capable of hauling cars by power or lowering them by the brake, and is in

FIGS. 1, 2 AND 3. SHOWING SOME APPLICATIONS OF THE ROOM HOIST

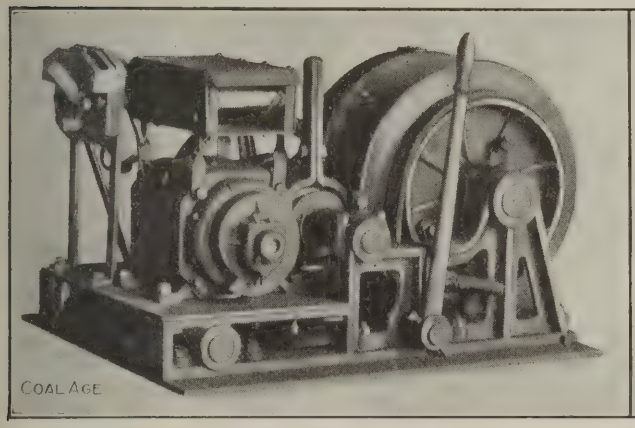


FIG. 4. THE ROOM HOIST WITHOUT FOUNDATION

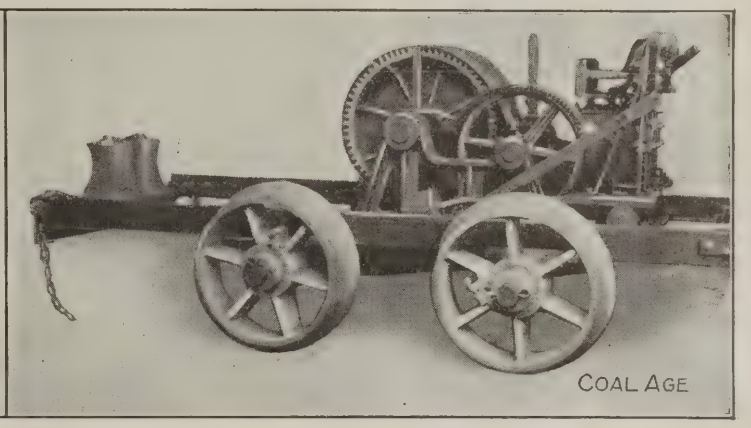

FIG. 5. ROOM HOIST MOUNTED ON A MINE TRUCK

FIG. 6. THE ROOM HOIST IN OPERATION

FIG. 7. CAP-STAN IN OPERATION

every way a small edition of larger electric hoists with which all mining men are familiar.

A special application of this machine is shown in Fig. 5, and some methods of its use are illustrated also in Figs. 1, 2 and 3.

This miniature hoisting engine is but 26 in. in height, 28 in. in width and 38 in. in length over all, and the weight without rope is only 830 lb. It may be seen from this that the machine is easily portable and can be used anywhere without the necessity of making an excavation for its accommodation.

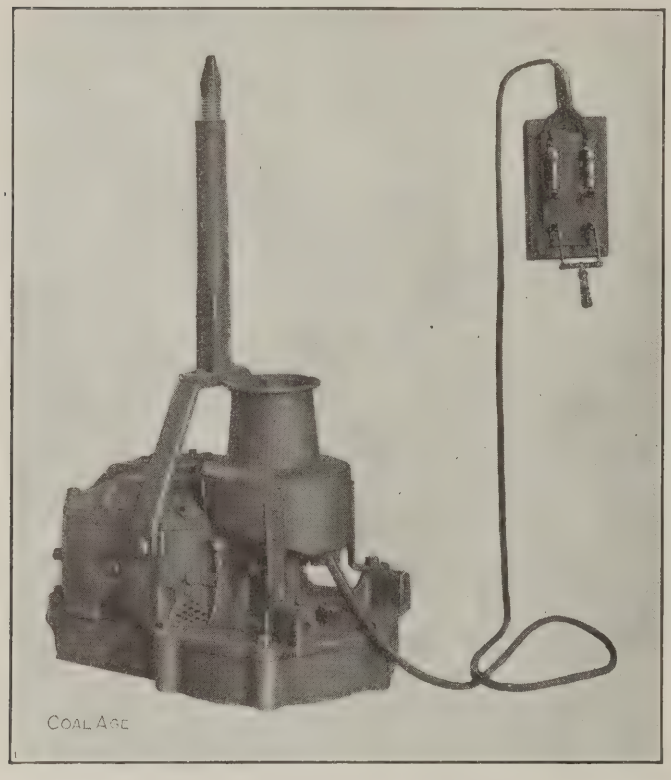

FIG. 8. THE ELECTRIC CAP-STAN

The Cap-Stan, illustrated in Fig. 7, is a novel application of electric power to hoisting or pulling purposes. The machine is especially designed for application to coal-mine work and is solely and primarily a pulling machine, there being no brake or other apparatus. The principle employed is that of the familiar vertical steam capstan, namely, the use of a hemp rope on a revolving spool or capstanhead. Fig. 8 clearly illustrates this principle.

Ordinary hemp rope used in this connection has the disadvantage of wearing rapidly, but a steel-center hemp rope, recently developed, has proved especially satisfactory for this service, since it combines the strength and wearing ability of metallic cordage with the flexibility and ease of handling of hemp.

The weight of the electric Cap-Stan is but 450 lb., and its dimensions are such that it can be used under any condition. The ruggedness and simplicity of this machine commend it for use under severe conditions and by unskilled labor. It will be at once apparent that the machine is virtually food-proof, inasmuch as there are but few parts, and the pulling principle which depends upon the friction of the rope on the spool or capstanhead will not admit of serious overload.

The Philadelphia Conference

Last week, we stated that the subcommittee on the new scale made a report on Wednesday morning, Feb. 25, to the joint conference. The operator members of that committee were as follows: Hugh Shirkie and P. H. Penna, of Indiana; C. E. Maurer and E. A. Cole, of Ohio; W. W. Keefer and G. W. Schleuderberg, of Pennsylvania. The miners represented were Joseph Moore and C. W. Savage, for Ohio; Duncan McDonald and Joseph Pope, for Illinois; Van Bitner and Robert Woods, for Pennsylvania, and Charles Fox and William Houston, for Indiana. The miners were allowed to select two alternates for Indiana, Lawrence Garrigas and Edney Buck, to represent the block-coal district of that state.

The conference finally adjourned on Feb. 26, having accomplished nothing though it had been in session since Feb. 10. The two features creating debate were Demands 1 and 7 of the Union. The first calls for payment for all coal mined, both lump and finer coal, and the second "that all the local inequalities and internal differences be referred to the various districts for settlement.

The operators desired the so called Cleveland agreement of 1912 which runs almost identically with the above, but has a most important qualifying clause:

> That internal differences be referred for adjustment to the various districts affected, it being understood that nothing shall be done in district or subdistrict conventions that will increase the cost of production or reduce the earning capacity of the men.

There are still three weeks before April 1, during which the conference will probably be called again.

BY THE WAY

The morning sun never lasts all day.

A monkey remains a monkey though dressed in silk.

If you don't scale the mountain, you can't view the plain.

It generally happens that where might is master, justice is servant.

Any man can bear another's misfortune like a good Christian.

Those who believe that money can do everything, are generally prepared to do everything for money.

The Sherman Law in restraint of trade might have been appropriately applied to the Ohio Mining Commission.

Five minutes talk with any coal producer will convince one that it is high time some philanthropic personage established a "Home for Indigent Coal Operators."

Dear sirs & Gentlemen i enclose you under separate cover herewith still anuther manyscrip article (with stamps as usual) and all I got to say is that i want to know why you all don't never print none of my articles cause I read everything in Coal age every week (includin & exceptin respectively the advertisements and the trade Reviews [and Believe Me them is Some advertisings]) and I aint never yet seen no one that had me skinned none in writin—and—and—(ad infinitum.)

Good Night!!

Types of Electric Winding Engines

By L. F. Mitten*

SYNOPSIS—Local conditions governing the service of hoisting engines which have a direct bearing upon the design are here discussed. The systems of electric supply and control common in the coal fields are also described.

The selection of the proper type and the design of an electrically operated hoist for slope haulage, where the rope speed is not high and the equivalent rope pull not excessive, is a comparatively simple proposition from the builders' standpoint.

The proper size of motor for a slope hoist where the load is pulled up and the empty cars lowered by mechanical brakes is determined by the following formula:

$$hp. = \frac{R \times W}{33{,}000 \times \text{efficiency of hoist}}$$

When R = rope speed in feet per minute, and W = equivalent rope stress in pounds.

In selecting the motor the rating should be based on

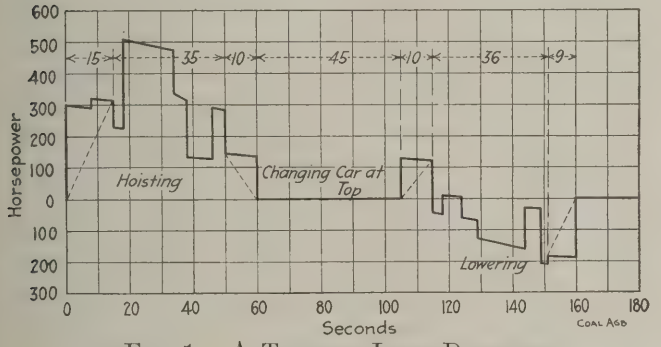

Fig. 1. A Typical Load Diagram

one-half hour or intermittent service, inasmuch as the machine is idle, and, therefore, allowed to cool, while the trip is being lowered and the rope transferred from the empty to a loaded trip, and *vice versa*. When the hoisting conditions differ from those given above (or when the rope speed is high with a resulting high starting peak) the conditions must be gone into thoroughly, a duty cycle given and the average heating determined.

Conditions Must Be Fully Known

To better show why the conditions must be fully known in order to determine the proper equipment, a typical load diagram is shown in Fig. 1. This diagram was plotted from the following data:

No. of cars per trip	1
Cars handled in 8 hours	140
Weight of loaded car, lb.	12,000
Weight of empty car, lb.	3,600
Diameter rope, in.	1½
Length of slope, ft.	1,005
Maximum rope speed hoisting, ft. per min.	1,270

A profile of the slope is shown in Fig. 2.

In this case the loaded cars are hoisted and the empty ones lowered, the braking being done mechanically. From this diagram the size of the motor required would have a continuous rating of 250 hp. The capacity of this motor would have to be increased if the braking was done by letting the machine run as a generator "pumping" power back into the line.

Figs. 3, 4 and 5 show hoists that are used on ordinary slope haulages where the rope speed is low and double reduction gears are necessary. Outfits of this type are built with friction, or loose drums, or with tight drums keyed to the shaft. The advantages of the friction drum are that in lowering the trip the drum is unclutched and there is, therefore, no wear to any part of the outfit with the exception of the drum bushings and brakes. Oftentimes it is absolutely necessary to have a friction drum on account of a slight pitch on the slope, which would not give a sufficient rope stress to turn the drum, gearing and motor over.

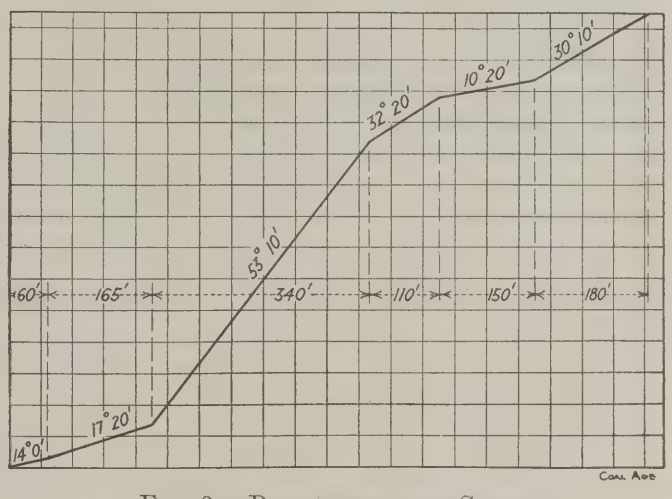

Fig. 2. Profile of the Slope

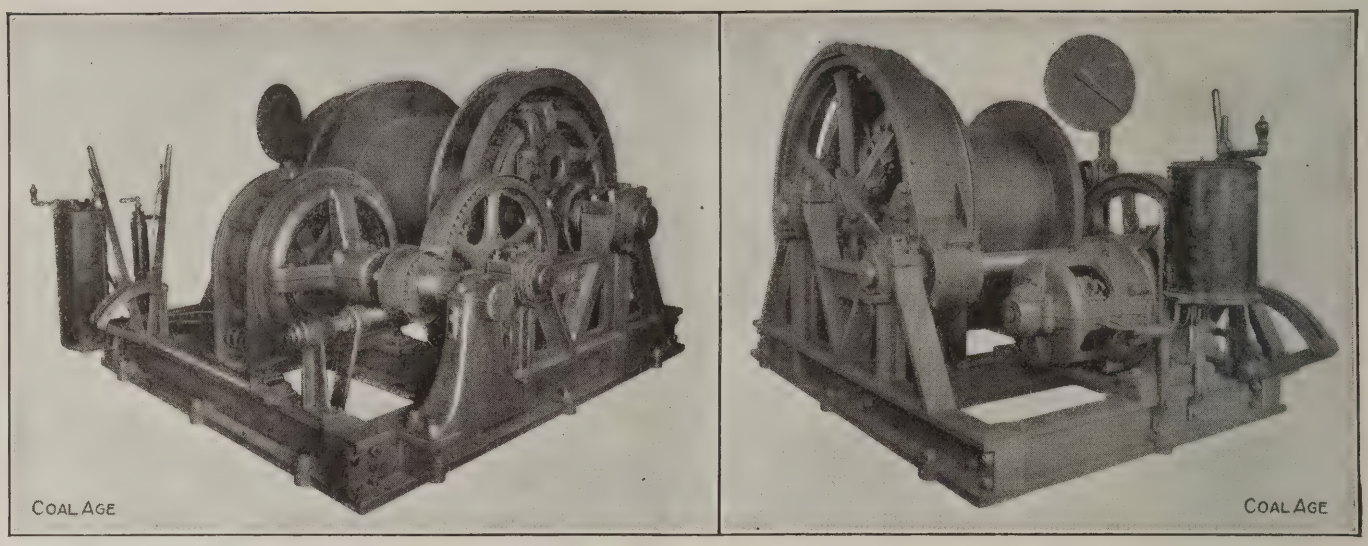
The tight drum has the advantage of low first cost and simplicity. One great disadvantage, however, is that should the descending trip exceed a safe speed the driving motor may be damaged owing to the high peripheral speed of the armature.



Figs. 6 and 7 are hoists designed for heavy rope stresses at medium speeds. The outfit in Fig. 7 handles a load of 26,000 lb. at a speed of 500 ft. per minute and is driven by a 500-hp. induction motor with a liquid-type controller.

Speed-Change Gears Are Often Employed

It is often necessary in the case of inside rope haulage to pull the load up heavy grades, for a short distance, the slope then flattening off. In such instances, in order to reduce the size of the motor, hoists with speed-change gears have been installed. An outfit of this type is shown in Fig. 8. The gears are shifted by means of hand levers, these being interlocked so that it is impossible for the operator to get both sets in mesh at the same time and damage the hoist.

As an example of the adaptability of this type of outfit, we will assume that under ordinary conditions it is desired to pull a load up an incline with a resulting rope stress of 5600 lb. at a speed of 500 ft. per minute. For this duty where the cycle of operation is not severe, as previously outlined, a motor having an intermittent rating of 100 hp. would be required.

*Engineer, hoist department, Vulcan Iron Works, Wilkes-Barre, Penn.

FIGS. 3 AND 4. ORDINARY SLOPE HOISTS WITH DOUBLE REDUCTION GEARS

Let us now assume that occasionally it will be necessary to bring supplies up this same slope, the load being increased so that the resulting rope stress is, say 9500 lb. The speed at which the motor would handle this load would be approximately in direct proportion to the rope pull, or at the rate of 295 ft. per minute. The hoist would, therefore, be designed to give these speeds at the full-load speed of the motor, and the outfit would, of course, have to be of sufficient strength throughout to withstand the maximum rope stress.

THE HORSEPOWER IS MEANINGLESS

The horsepower rating of an electric hoist means practically nothing, as far as the size of the machine is concerned. As an example, a hoist is designed for a maximum rope pull of 6000 lb., and is driven by a 75-hp. motor with gearing to give a rope speed of 350 ft. per minute. This same hoist could be adapted to be driven by a 150-hp. motor at a rope speed of 700 ft. per minute, provided the acceleration period is not so short as to create stresses that would exceed the safe capacity of the machine, with but little change in the mechanical construction.

We will now assume that an outfit is desired with a smaller motor, say 50 hp., and designed to give a rope

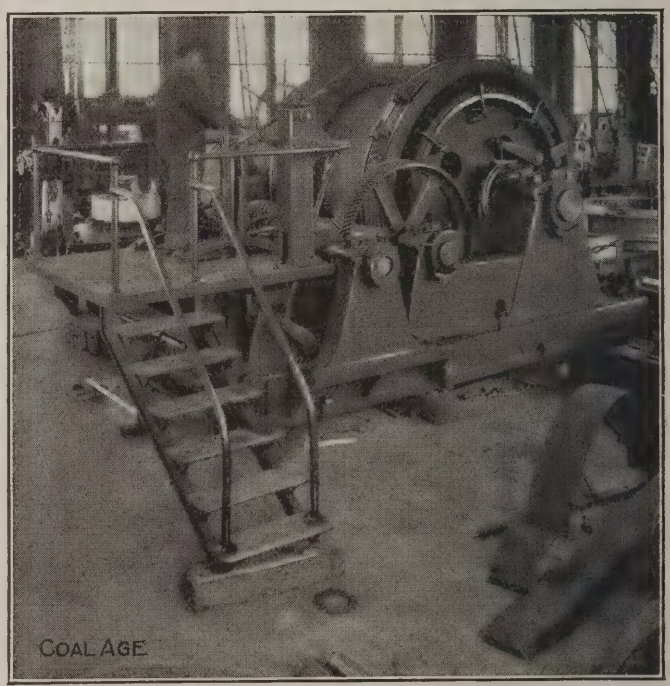


FIG. 7. A HEAVY-DUTY MEDIUM-SPEED HOIST

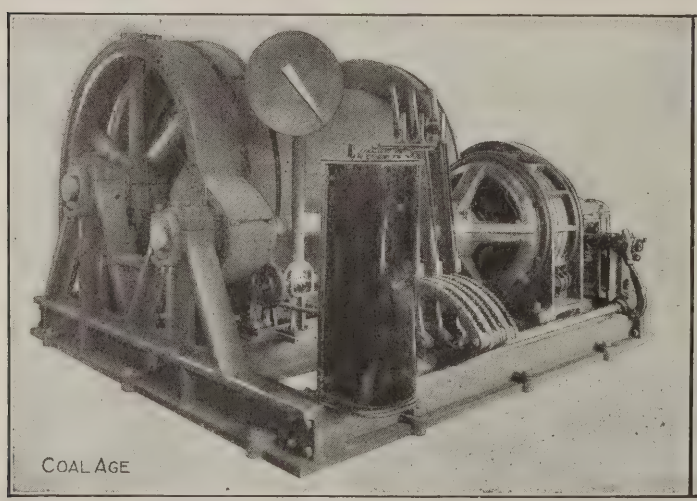

FIG. 5. ANOTHER DOUBLE REDUCTION HOIST

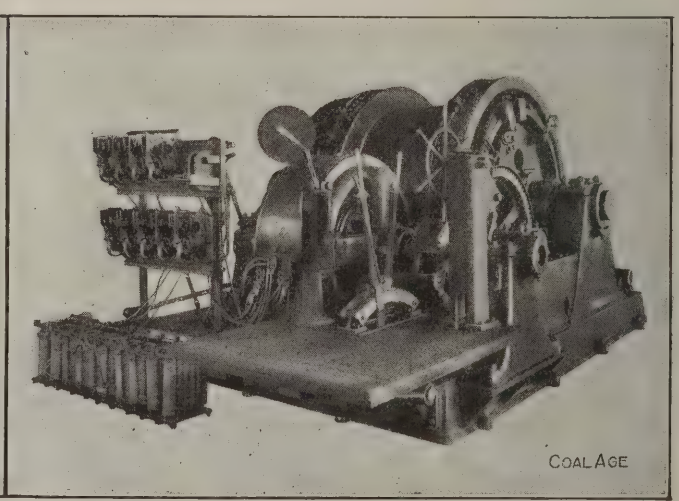

FIG. 6. A HOIST BUILT FOR HEAVY ROPE STRESSES

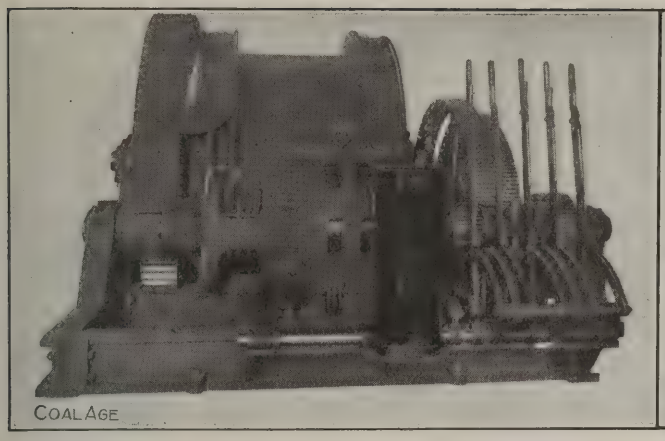

FIG. 8. A HOIST PROVIDED WITH CHANGE GEARS

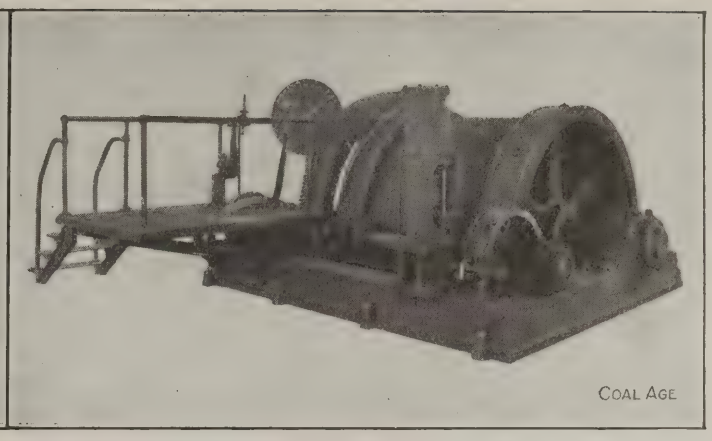

FIG 9. A HOIST WITH SINGLE-REDUCTION HERRING-BONE GEARS

speed of 100 ft. per minute. This motor would then handle a load of

$$\frac{50 \times 85 \times 33{,}000}{100} = 14{,}000\ lb.$$

equivalent rope stress. For this load a much stronger and heavier hoist would have to be selected.

In the foregoing examples the heating of the motor due to accelerating the load has not been taken into consideration, inasmuch as the rope speed is low and the acceleration peak may be neglected.

One of the objections to the electric winding engine is the noise from the gears. This has been practically eliminated, however, by the use of gearing of the machine-cut herringbone type. These gears work silently and without backlash or vibration, friction and mechanical losses are greatly reduced and much higher ratios and velocities may be obtained. Herringbone gears are higher in first cost than machine-cut spur gears, but are preferable in all cases where high rope speeds are desired. A hoist with the ordinary foundry-molded gears should not be given serious consideration under any conditions.

Fig. 9 shows a hoist with single reduction herringbone gears of the Weust type, having a ratio of 12 : 1. Fig. 10 has the same type of gear and is a modern installation in every way. This hoist has a rope speed of 1800 ft. per minute and handles the following load on a slope having an inclination of 30 deg. from the horizontal:

Weight of cars and ore, lb.	63,600
Weight of ore, lb.	33,600
Diameter of rope, in.	1½
Length of slope, ft.	1,800

The load is counterbalanced by a weight of approximately 45,000 lb. This is operated on a two-part rope and has a travel of 900 ft. The drums are 10 ft. diameter and wind the rope in two layers. The motor is a 700-hp., 290-r.p.m., 3300-volt, 3-phase, 25-cycle General Electric variable-speed machine with polar-wound rotor. The speed is varied by cutting resistance into and out of the rotor circuit.

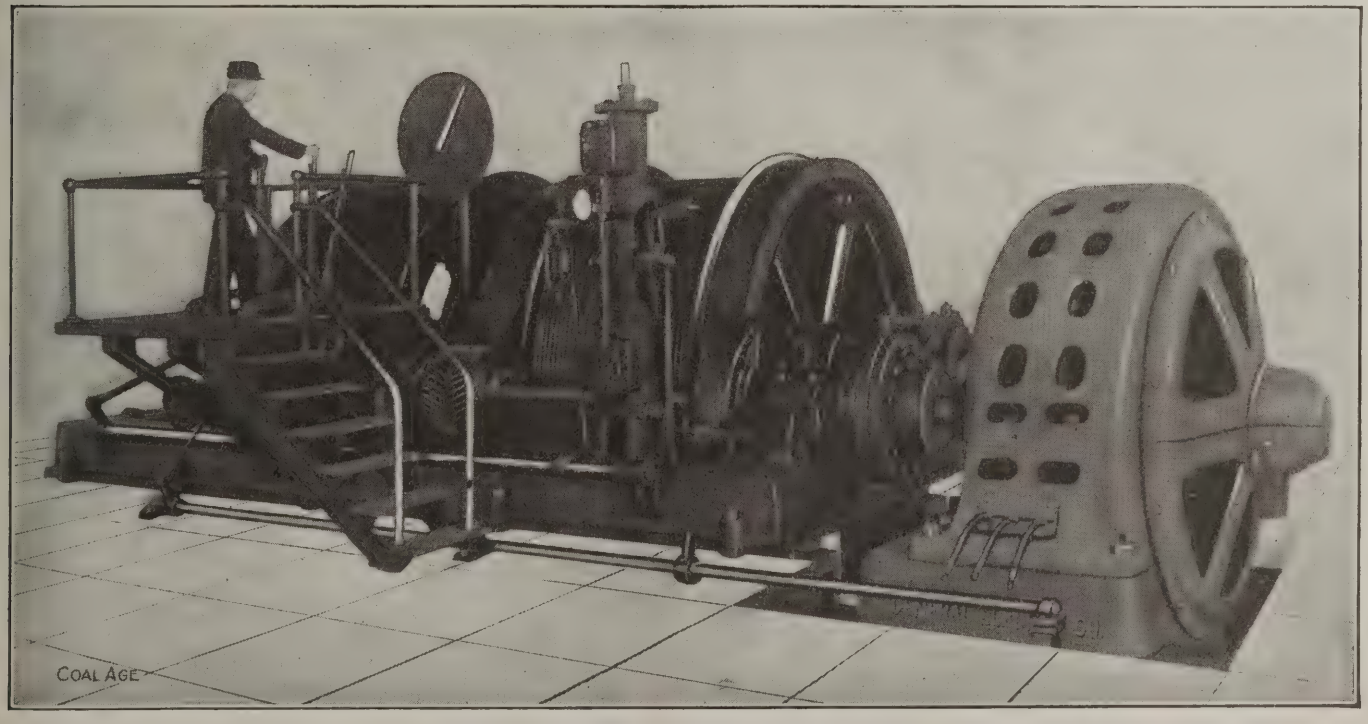

FIG. 10. A HOIST BUILT TO HANDLE 63,600 LB., PARTIALLY COUNTER-BALANCED ON A 30-DEG. SLOPE AT A SPEED OF 1800 FT. PER MIN.

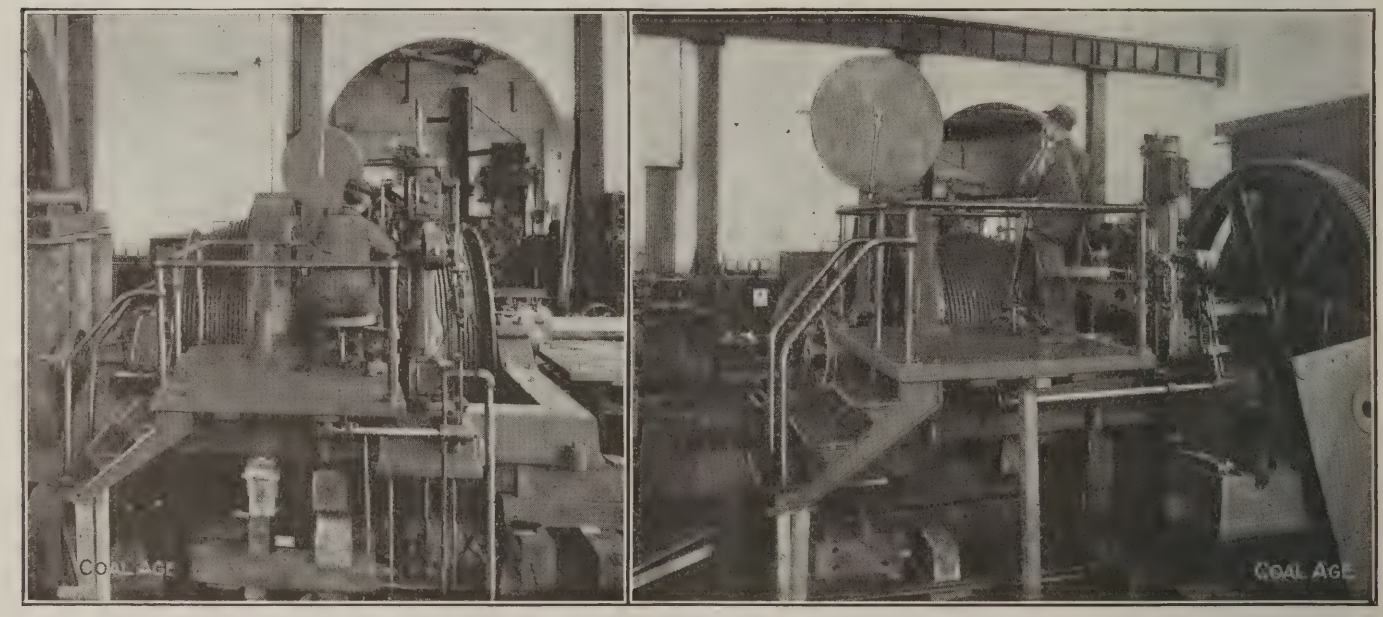
The rheostat is of the liquid type. The electrodes are connected to the collector rings of the motor, and the resistance in series with the rotor winding is varied by changing the level of the water in the rheostat by raising or lowering a hand operated weir.

The rate at which the water level may be raised, and therefore the rapidity of acceleration of the motor can be made independent of the weir so that automatic acceleration can be obtained, while the lowering of the weir for retardation can be done very rapidly.



The motor is connected to the hoist through a flexible coupling. Each drum is equipped with an extra-heavy band brake, one being operated by a weighted power cylinder of the floating lever or compensated type. This permits of the band being applied partially or set up tight, as may be desired.

The general design is very similar to the one shown in Fig. 9, with the exception that the drums are conical and the brake is of the post type, having a parallel motion. The conditions under which this hoist operates are as follows:

Depth of shaft, ft.	190
Weight of cage, lb.	11,000
Weight of car lb.	2,650
Weight of coal, lb.	4,500
Diameter of rope, in.	1⅜
Maximum rope speed, ft. per min.	1,140
Caging rest, seconds	8

Fig. 13 shows the load diagram plotted from the above data and from which the size of motor was determined.

The method of calculating the sizes of driving motors and the plotting of load diagrams is an interesting study, but would lead too far for this article.

FIGS. 11 AND 12. ELECTRICALLY OPERATED SHAFT HOISTS WITH CONICAL DRUMS

The hoist is equipped with the usual safety devices which bring the drums to a dead stop should the operator pull into the danger limit. In case of failure of power supply the machine is also brought to a full stop. A motor-driven compressor for supplying power to the auxiliaries is located in the hoist house.

SHAFT HOISTS WITH CONICAL DRUMS

Figs. 11 and 12 show electrically operated shaft hoists with conical drums driven by General Electric 300-hp., 450-r.p.m., 2300-volt, 3-phase, 60-cycle, form "M" induction motors. The speed of these machines may be varied and controlled by cutting resistance into and out of the rotor circuits.

The resistance is of the cast-iron grid type and is short-circuited by a contactor operating from a master controller. A geared limit switch is driven from the drum shaft and when the cage approaches the surface there is inserted a block of resistance, bringing the hoist to the slow-running speed. Should the cage fail to stop after passing the landing, this limit switch opens the contactor circuits and applies a weighted, compensated brake, such as has been previously described. This operation, however, takes place only in the event of the operator neglecting his duty.

THE CHOICE OF POWER SYSTEM

In the case of large electric hoists there are a number of systems from which to choose and each installation must be gone into thoroughly in order to determine the system best suited for local conditions.

The system that is used in practically all cases in the Pennsylvania coal fields is the straight induction mo-for, geared to the hoist drums through single-reduction herringbone gears, similar to Figs. 9, 10, 11 and 12.

A system that is used in a number of installations is a direct-current shunt-wound motor, direct connected or geared to the drum. This machine gets its power from a synchronous or induction-motor-generator set. With this arrangement a separate motor-generator set must be installed for each hoist motor inasmuch as the latter is controlled by varying the voltage of the generator.

Still another system is a direct-current hoist motor with a motor-generator set practically the same as that described with the addition of a flywheel for the purpose of storing up energy and an automatic speed regulator.

The first system has the advantage of being low in first cost which is of prime importance in many installations and in most cases the efficiency compares favorably with the other systems.

Hoist Delays Cover Much Time

The great objection in the coal field to the direct-current hoist motor driven by a motor-generator set is that the delays in hoisting cover a considerable period; in fact, during an eight-hour day the actual time consumed in hoisting would be from four and one-half to five hours. In addition to this it is necessary to lower men and supplies into the mines during the day and at night, in which case the motor-generator set would have to be kept running. The stand-by losses would, therefore, be considerable, and this, together with the high initial cost and maintenance, make the induction-motor drive the only practical solution.

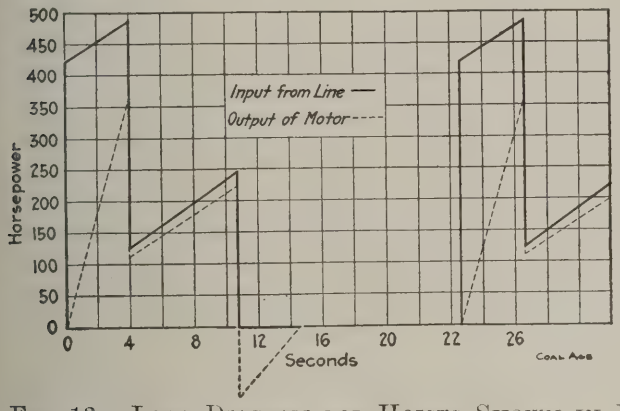


Fig. 13. Load Diagram for Hoists Shown in Figs. 11 and 12.

Wherever it is imperative that the peak load be kept down, owing to the size of the power station, or where current is purchased and peak loads are penalized, the flywheel motor-generator set is usually the only solution.

Each system has its advantages and disadvantages and these can only be brought out by taking up each individual case separately after knowing local conditions. Examples showing power consumed per ton of coal hoisted by each of the foregoing systems for a given depth of shaft lie beyond the scope of this article.

In conclusion I would say that in all cases where electric hoists are being considered, complete information relative to operating conditions should be given the hoist manufacturer, so as to enable him to determine the type best suited for the duty.

Rhenish Westphalian Coal Syndicate

In the report on the trade and commerce of Dusseldorf (Westphalia and the Rhenish Provinces) for the year 1911, presented to the British Houses of Parliament, it is stated that toward the close of that year the Prussian Government began to negotiate with the Rhenish Westphalian Coal Syndicate with a view to turning over the whole coal production of the government mines for sale through the syndicate.

Early in 1912 an arrangement was concluded between the government and the coal syndicate, under which the production of the government's mines in Westphalia and the Rhenish provinces is sold by the syndicate. Previous to the government's decision there seemed to be doubts as to whether the syndicate would be renewed, as there were a number of private owners who were desirous of withdrawing. But now that the government has joined the syndicate, all the coal companies will likewise be compelled to join.

As the report explains, the Prussian Government works a large area of coal fields in the Saar district of the Rhenish province, and also has large interests in some of the most important companies in Westphalia. It is a well known fact that the coal mines managed and worked by the government do not pay as well as those in private hands. The Government has attempted in the past to counteract exorbitantly high prices and to be independent of the private companies.

In the view of the Consul-General the recent agreement points to a change in that policy, and the competition which formerly existed between the government and the mining companies will cease. The result of this agreement is that since Apr. 1, 1912, the Rhenish-Westphalian Coal Syndicate has raised the price of coal and coke all around.

The Proper Use of Oils

By James R. Williams*

Lubrication is the introduction of a medium between two moving surfaces, which will keep them apart and prevent them from seizing or abrading each other.

To secure efficient lubrication, it is not only important to use a good lubricant but it is also necessary that all main bearings, crank pins and cross-heads be kept in proper adjustment, and that all oil holes should be open down to the journal or the part to be oiled. Apply only small quantities at a time, and when oil cups are used, as they should be wherever possible, the feed should be adjusted to the smallest quantity necessary to keep the parts well lubricated. It takes only a small amount of oil to pass between two surfaces, between a revolving journal and a stationary journal brass, or between a sliding contact, such as a cross-head and guide. All material in excess of the amount necessary runs off and goes to waste or drops down on the parts below the point of application, causing an untidy appearance. This wasted oil has been crowded out of the journal before performing its mission. Furthermore, it picks up dirt and grit that are so harmful to smooth surfaces.

Cylinder Oil

Cylinder oil, as the name implies, is intended for use in cylinders only, and should not be used for any other purpose. It may be applied to advantage, however, on hot journals, but its use should cease when the journal is cooled. Some engineers think that cylinder oil is improved by mixing a little graphite with it. This is doubtful; for the tendency of graphite when mixed with cylinder oil is to separate and drop to the bottom of the lubricator. When this mixing is practiced there is always a danger of depositing some of the graphite between the piston rings and the piston body, thereby preventing the rings from performing their duties properly.

Engine oil is especially adapted to the lubrication of all external parts of engines. Being more limpid than cylinder oil, it will spread over the bearing quicker, and will reach all parts to be lubricated in much less time than

*Galena Signal Oil Co., Franklin, Penn.
Note—Abstract of an article in the "Employees' Magazine," January issue.

either cylinder or car-journal oil. The latter oils will lie in heaps. If used on a cross guide they will be pushed off with the first stroke of the cross-head. Engine oil should not be mixed with other oils for any purpose. Its use should be confined to the lubrication of engine bearings, because it finds its way to the journal and fills up the irregularities of the bearing, thereby increasing the smoothness of its surface. It should never be used in steam cylinders, either by itself or mixed with cylinder oil, because it disintegrates when raised to high temperatures.

Oiling the Engine

Upon entering the engine house prior to starting up, especially if the engines have been idle for some hours, the engineer should open the cylinder cocks to allow any water that might have accumulated to escape. They should also be left open for a little while after starting, to allow the escape of the steam which the lower temperature of the steam pipes and cylinder walls causes to condense. The neglect of this important precaution might result in serious personal injury, damage to the engine and throwing the entire colliery out of work for some time.

The cylinder-oil lubricator, if of the sight-feed type, should be adjusted to feed about five minutes before starting the engine. If of the mechanical-feed type it should be operated by hand a few times to give the cylinder a good initial lubrication. The oil cups on the crank pins, cross-heads, main journal and all other bearings should be set to feed two or three minutes before the engine is started. This precaution is especially advisable with the crank-pin cup, because an abrasion of the metal at this point might cause expensive trouble and delay.

Importance of Cleanliness

Great care should be taken to prevent dust and dirt from getting into the engine room. The oft-given advice to keep all oil and grease cups covered should be religiously observed. Hot bearings are liable to occur when dirt or grit is carried into them by the oil, even though the oil is of the best. Drip pans should be used wherever necessary and the waste oil contained therein dumped into the filter frequently.

It has been my experience that where an engine house and its machinery are kept clean and tidy, trouble of any kind rarely occurs. Before leaving the engine house after the day's work is over, all windows and doors should be closed, and all waste or inflammable material of any kind should be put into a covered metal can. The feeds on all oil cups and lubricators should be closed, and if the latter are nearly empty they should be filled ready for the start next morning, it being understood, of course, that reference is made only to engines that are in daily service and worked single shift.

The Care of Wire Rope

SYNOPSIS—If a wire rope is carefully watched at work it is possible to prevent much wear and tear. The article describes where the deterioration is to be expected and the cure for it is obvious.

Experience has taught that there are four leading causes for the destruction of wire rope, namely, abrasion, overstrain, undue bending and corrosion. In time, one or more of these causes will so weaken a rope that it can no longer support the load for which it was designed. When it fails, from any of the above mentioned reasons, the cause can usually be determined from the appearance of the rope. If, for example, the wires wear thin in a short time, the rope has been subject to abrasion; if the wires are but little worn and broken off squarely, usually sticking out all over the rope, it has suffered from either severe bending stress or overstrain; and if the wires are rusty and pitted, corrosion is to blame.

Causes of Abrasion

Abrasion in a wire rope is frequently the result of one of the following causes: (1) Faulty grooves in wheels that are roughly worn or too tight for the rope.

(2) Dragging of the rope upon the ground or over some fixed obstruction.

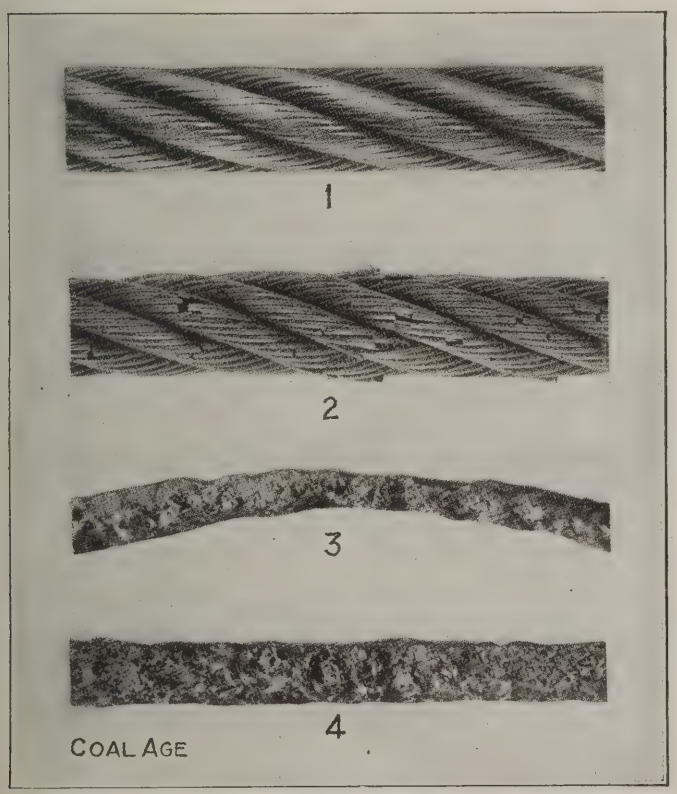
(3) Using a rope under conditions for which none but the toughest steel (plough or improved plough) is adapted, and failing to select ropes of such grades.

Another cause for sudden breaking may be excessive abrasion at some point. This may occur to ropes running on slopes over heavy knuckle sheaves. After the train has come to a rest, if the sheave keeps on spinning, it tends to wear the portion of the rope resting upon it, and that part will slowly wear and become weak.

Causes of Broken and Corroded Wires

Badly broken wires, showing excessive bending, indicate that the wheels are too small or too numerous. They should be rearranged or a more flexible rope used.

Rope badly corroded shows the lack of proper lubrication. Local corrosion sometimes causes failure. If, in passing through a tunnel in which water is dripping from the roof, a rope is allowed to lie still for a considerable length of time, the part exposed to the drippings will rust faster than the rest.



In addition to the destructive causes mentioned above, ropes sometimes suddenly tear apart. Such cases are invariably the result of accidents to machinery or appliances, which bring upon the rope a load far beyond its capacity, or they are due to a serious weakening of the rope at the point of rupture, caused by some local abuses. Such abuse should by all means be avoided. A new rope made from the materials and with the care that distinguishes "A-1" quality, is sent from the factory as nearly perfect as a mechanical product can be and the purchaser should protect the rope from those injuries which may with very little care be prevented.

One of the most common of these injuries is the damage arising from "kinking." If for any reason the rope is allowed to form a loop, and this loop is drawn taut, a kink will result. Though the kink may be straightened out, it leaves a permanently damaged and weakened spot and so should always be avoided.

Note—From the January issue of the Employees Magazine, published by the Lehigh Valley Coal Co. This article was furnished by the John A. Roebling's Sons Co.

When a running rope has a socket attached to the end, constant vibration tends to weaken the wires, and this weakness is increased if water collects directly over the end of the socket. It is, therefore, advisable every three to six months to cut off a piece from the end of the rope and reattach the socket.

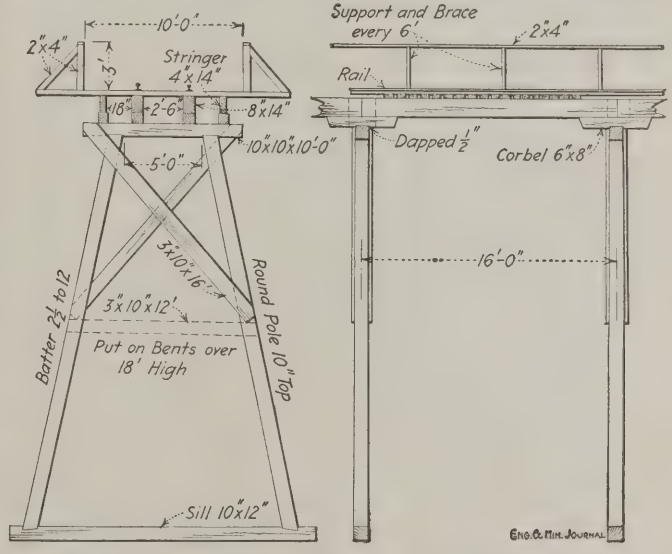
Besides the causes mentioned, the effects of which are usually revealed by inspection, temporary overloads producing excessive stresses are sometimes applied, and by straining the wires beyond their elastic limit these tend to shorten the life of wire rope. Such excessive stresses are more apt to occur where a rope is slack, or is attached to a short length of slack chain, and the power to lift or haul a load is suddenly applied, with the result that, instead of the rope gradually adapting itself to the required pull, it is subjected to the jerk arising from the full inertia of the load. Lifting tests made on wire ropes, attached to chains having from 2½ in. to 12 in. of slack attached, show that when loads are applied sud-

1—Wire Rope Used under Proper Conditions, Shows Normal Wear. 2—Wire Rope That Has Been Subjected to Short Bends, Causing Broken Wires. 3 and 4—Enlarged Views of Pieces of Wire Taken from Badly Rusted Rope

denly, the stresses are from one to four times as great as those sustained when the same loads are gradually applied. Therefore, care should be taken to avoid, as far as possible, such pulls and jerks.

Wire-Rope Lubrication

When a complaint is made that a wire rope has not given satisfactory service, the first questions asked by the manufacturer are: "How was the rope lubricated?" "What is the condition of the inside wires?" These questions arise because the experienced wire-rope maker fully appreciates that a wire rope is a complex piece of machinery and knows that the importance of proper lubrication is too often overlooked. Sometimes a wire rope is covered with a compound too thick to penetrate beyond the outside wires. The effect of this is to leave the inside strands without protection against water and moisture.



Examinations of ropes that have fallen short of the period of good service, frequently show the outside wires to be in apparently good condition, while the areas of the inside wires have been materially reduced and the whole rope weakened. This is due to corrosion that could have been prevented by the use of a lubricant which would have reached and protected the inside wires.

A lubricant or preservative should not only penetrate to the hemp center, in order to saturate it and prevent absorption of water, but it should also coat thoroughly the inside wires of each strand. This cannot be expected from thick, heavy and sticky compounds or the greases frequently used for the lubrication of wire ropes, which were made primarily for some other and quite different purpose.

Wood Trestle for Motor Tramming

By William Wallace

From a typical iron-range shaft several trestles usually lead off, one or two for the ore stockpile, one for the waste rock and a short one for a tail track, when motor tramming is employed. The bents of these trestles are sometimes steel, more frequently wood, and in the latter case are often temporary. The accompanying illustration

Elevation Showing Details of Construction

represents a rather typical bent of light construction. It is designed for a load of 10 tons, that is, a loader car and an electric locomotive. The material specified is hemlock, except for the posts which are cedar, spruce, or tamarack round poles. Such a trestle will range in height from 15 to 50 ft., although for the higher structures, three or four posts are used in the bent. The stringers instead of being sawed timber, are frequently hewed poles, which may be lapped and the corbels eliminated. The full sill shown here is often omitted on a temporary bent and 1x6-ft. bearing blocks used under the various posts. —*Engineering and Mining Journal.*

The Congressional Investigation in Colorado

SYNOPSIS—The operators admit the importation of arms, but declare that it was done to protect their property. They show clearly that the men were making good wages and had saved over a half million dollars. The right of the committee to subpoena witnesses who are held by the governor, is denied.

In the coal-strike hearing the importation to Colorado from West Virginia of rapid-fire guns for use during the strike in the southern field was the subject of considerable investigation by the Congressional committee while in session in Denver. Albert C. Felts, of the Baldwin-Felts Detective Agency, testified to having shipped four such guns together with 4000 rounds of ammunition, but that this was not done until after murders had been committed by the strikers. He claimed that the arms were secured for protection and not for offensive warfare, and that the freight on them had been paid by the operators. John G. Osgood, president of the Victor-American Fuel Co., declared that he would assume full responsibility for his share in the importation of the arms, and stated that they were not used by anybody except the sheriffs.

OSGOOD'S TESTIMONY

Osgood declared that violence, on the part of the strikers, began the first day of the strike and that altogether he believed 11 company men and three strikers have been killed. He accused the strikers of many depredations, such as the burning of bridges and attacks on nonunion camps. He testified that there is no formal organization among the coal operators of the state, but that they have frequently met in one another's offices for consultation, inasmuch as their interests are largely common. Both Osgood and J. F. Welborn, president of the Colorado Fuel & Iron Co., emphatically stated that they did not wish to and would not deal with the United Mine Workers of America, Welborn saying, "I am going to run my own business or not have any business."

These men explained their attitude in this matter as based upon the fact that the union, being unincorporated, is not a responsible body and does not abide by its contracts nor can be forced to do so. Osgood said that while he is personally opposed to the eight-hour law that has been in force for about a year in Colorado coal mines, he has enforced it. He believed that the miners themselves preferred not to be limited to the short hours, for their work is seasonal, the mines frequently running on short schedule during the summer months. Numerous canvasses of the men on this subject, he claimed, showed that the miners were opposed to the eight-hour restriction. Referring to troubles arising over disputed weights of coal, Osgood said he was glad to have checkweighmen at his mines but that it is always difficult to find men who will accept such positions.

SCRIP AND SALOON REGULATION ARE NECESSARY EVILS

Questioned regarding the use of "scrip," he explained that his company inaugurated the system as a convenience to the miners who are never obliged to trade at company stores and are not discriminated against if they trade elsewhere. He is opposed to the system on the ground that shiftless miners often use scrip in payment for saloon bills. He stated that his company had no relation with the saloons of the coal camps except to regulate them somewhat for the benefit of its employees. At some of the camps, his company had established "clubs" where liquors and tobacco were sold at reduced prices that effected savings, for some men, of about $5 per month.

He said that one notorious saloon, flaunting a red flag with a bowie knife on it, was frequented by anarchists and that the company had raided it a number of times. Osgood further declared that his company had done everything it could to comply with the new coal-mining code and had even anticipated some of the demands. He also explained the organization of rescue crews and the purchase of a car fully equipped for instruction, two years ago. So far as he was concerned, he said, the strike was over, for his company is producing more coal than the market demands.

Welborn declared that his company had already spent $250,000 resisting the present strike but that this expenditure was preferable to recognition of the union. He created some surprise among the members of the Congressional committee when he asserted that the strikers had about $400,000 in money deposited with his company. The corporation has a system of notes whereby miners may deposit their earnings, and when the strike began such deposits amounted to about $500,000. Questioned concerning the need for the militia now, Mr. Welborn said that, although the strike is settled, so far as production of coal is concerned, violence is still imminent. Concerning scales of pay, he testified that the average pay for miners in his company's mines just previous to the strike was $3.84 per day. Both Osgood and Welborn denied any interference with the political liberty of employees and disclaimed any part in the control of local elections.

MOTHER JONES

After the taking of testimony from these two large operators, the work of the investigation was transferred from Denver to Trinidad, where it was resumed Monday, Feb. 16. About the first important feature to occur in the work at Trinidad was a scathing attack on Gen. John Chase and the militia in general. Horace N. Hawkins, attorney for the union, filed a habeas corpus petition on behalf of Mary ("Mother") Jones, who has been held military prisoner since Jan. 12 in a hospital at Trinidad. The document sets forth many alleged acts of the militia that are contrary to the Federal and state constitutions.

When the Congressmen proposed to subpoena Mrs. Jones, Major E. J. Boughton, judge advocate for the National Guard, objected on behalf of Governor Ammons. He declared that neither Congress or any of its committees has any power to subpoena persons held incommunicado by a state militia acting under the orders of the governor. Lengthy discussion ensued which much surprised the Congressmen. The position assumed by the military authorities and the governor rests upon a decision of the supreme court of Colorado some years ago, during the Cripple Creek strike, on the appeal of Charles H. Moyer, president of the Western Federation of Miners, for a writ of habeas corpus; and also upon a decision of the United States supreme court in a civil suit afterward brought by Moyer against Governor Peabody. The state supreme court decided that the governor is the supreme power whenever he has declared a state of insurrection to exist. In the present instance, Major Boughton declared that the public presentation of "Mother" Jones would incite riot. John R. Lawson, of the United Mine Workers, made a plea for Mrs. Jones and agreed to assume full responsibility for any disorder that might result from her presence in public. This elicited a noisy demonstration, requiring sharp criticism from Chairman Foster, who threatened to hold further hearings in secret session.

The committee wired to the Governor, in Denver, requesting him to direct the military authorities to bring Mrs. Jones before the committee. To this the governor replied by wire that he would obey the request but would prefer that her testimony be taken either at the hospital or in Denver. The evidence taken on the second day at Trinidad was from witnesses produced by the strikers and was intended to prove that the militia had been guilty of numerous assaults upon strikers and had interfered with postal rules in preventing strikers obtaining their mail at the post office. Two miners testified that they had been turned back from the post office, and that when some miners had resisted such interference, they had been attacked with muskets. One Michael Skidoda created much amusement by his ludicrous and dramatic description of such mistreatment, and required frequent reprimands from the chairman. The testimony of several strikebreakers was taken to prove that they had been brought from Pittsburgh under misrepresentations concerning the existence of a strike.

A PITTSBURGH STRIKE BREAKER

But to offset their statements, the operators called upon Charles Morgan, who testified that he came from the East, with other strikebreakers, fully aware of conditions. Contradicting statements made by preceding witnesses, he declared that traveling conditions were satisfactory throughout the trip, that he had never had any trouble with the militia, and that he had never known it to disturb anyone who was not drunk or disorderly. He considered the conditions of miners here better than they are in Pennsylvania, where he had worked for years. He scored the immigration of foreign, nonEnglish-speaking miners. A woman witness charged the militiamen with much drunkenness. Another woman who had been active in a street riot and was held

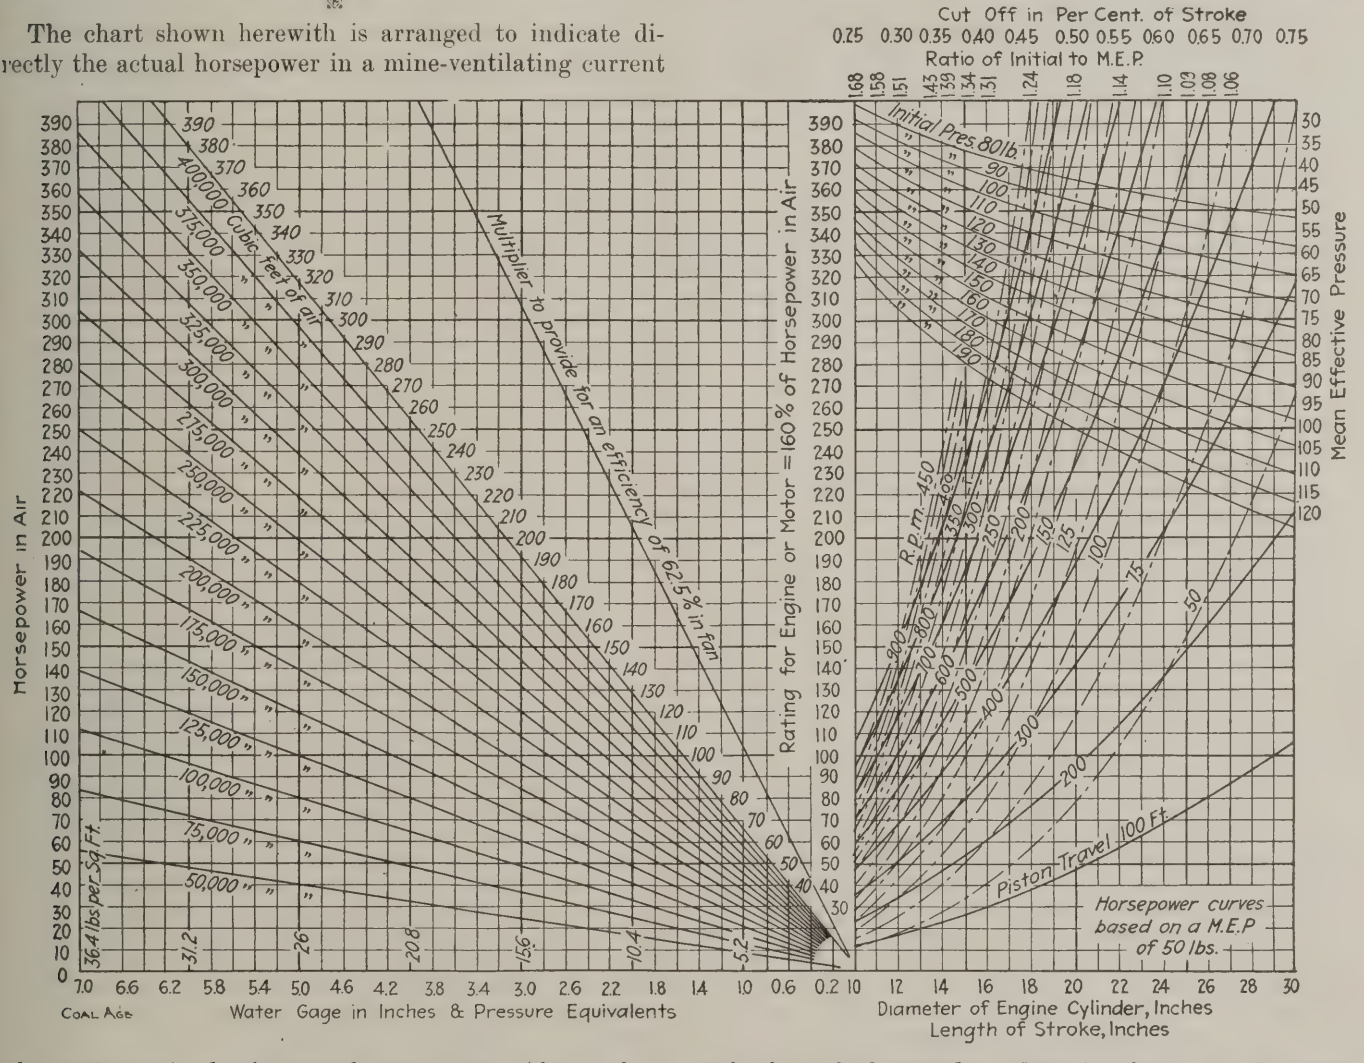
under arrest 11 days, complained of the filth of her prison quarters and of the food furnished her.

THREAT TO WRECK A TRAIN

A fireman and a brakeman engaged on the Colorado & Southern R.R. claimed that they had been arrested by the military authorities for refusing to pull a train in violation of the law that regulates the working hours for train crews. John H. Abrams, superintendent at Trinidad for the same railroad, related the receipt of a telegram warning him not to permit a passenger and mail train to pass a striker's tent colony at Ludlow. He took the train as far as Forbes Junction and then sent a messenger afoot to the colony, with the assurances that the train carried no deputies, before he was told that it would be safe for the train to proceed. During the day, Representative Evans, of Montana, secretly visited this tent colony to obtain personal information. The following day, the committee spent its time visiting the coal camps and interviewing the strikers. It is anticipated that the inquiry will soon come to an end.

An Air-Power Chart

By D. Gerber*



SYNOPSIS—A chart is here presented by means of which if the volume of air handled and water gage are known, we can determine (1) the actual horsepower in the air, (2) the horsepower necessary for the engine or motor driving the fan, and (3) the diameter of the cylinder. In the latter case, we are to assume the piston speed.

The chart shown herewith is arranged to indicate directly the actual horsepower in a mine-ventilating current of a predetermined volume and water gage. Also to show the commercial rating of a motor or steam engine required as a source of power. In the event of using a steam engine for power, the diameter of the engine cylinder required for a given piston speed may be read directly from the chart.

The calculations for cylinder diameters are based on a mean effective pressure of 50 lb. per sq.in. For other mean pressures it will be necessary to interpolate. As noted on chart, the assumption is made that the mechanical efficiency of the fan is approximately 62½ per cent. This percentage may be taken at any figure, however.

In general, the chart is constructed with a water-gage scale along the lower edge, advancing from near the center of bottom border toward the left. Above this scale is a group of converging lines, used to represent volumes of air in cubic feet, and a single inclined line passing through the common converging point. This line serves as a multiplier to obtain a proper figure for power under the assumed efficiency of 62½ per cent.

The vertical line passing through the point of convergence is graduated to show the rating of the prime mover.

*Pittsburgh, Penn.

the series of (heavy lines) curves to the right of horsepower scale, represent piston speed in feet per minute. Extending to the right from the common converging point, along lower border is a scale-reading diameter of engine cylinder and may be read in connection with horsepower value and piston speeds.

The graduations used to represent cylinder diameters may also be used to designate length of stroke, and when read in connection with the light (dot and dash) curved line, marked revolutions per minute, a continuation reading of stroke revolution from which piston speed may be read. Care should be taken in making such a reading to avoid confusing the length of the stroke and the diameter of piston.

In the upper left-hand corner of right portion of chart there is a group of curved lines from which may be obtained a value for the mean effective pressure corresponding to any point of cutoff for a range of initial pressures.

By the initial pressure is meant that at engine throttle or near it. These values do not have any direct connection to the work done by the chart, but serve as a ready means of arriving at a value for a mean effective pressure with which the charted results may be checked.

An Example to Illustrate Method of Using Chart

The method of using chart may be readily understood from the following example:

Example—It is desired to know the horsepower in a volume of 275,000 cu.ft. of air moved against a pressure of 3½ in. of water gage, the horsepower of a suitable motor or engine to drive a fan, having an efficiency of 62½ per cent., of the above capacity, also the diameter of cylinder of this engine, the piston speed of which is 500 ft. per minute, the mean effective pressure to be 50 lb. per sq.in. Find the 3½ graduation in water-gage scale and read up to a line marked 275,000 cu.ft. of air, thence to the right to scale reading actual horsepower in air and read 152, thence up to the line marked multiplier, thence to the right to horsepower-rating scale and read 242 horsepower.

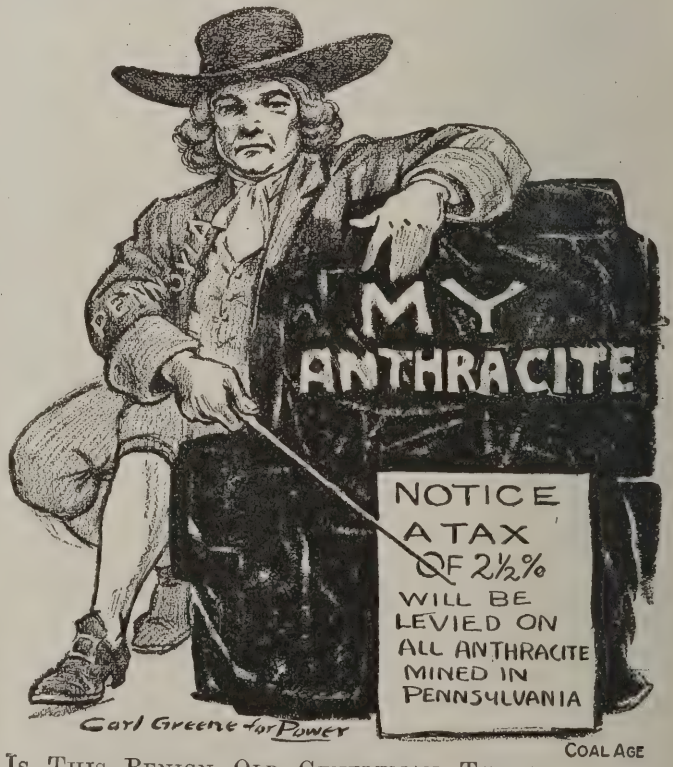
Note that these ratings are based on a mean effective pressure of 50 lb. per sq.in. Should the pressure be more or less in connection with any problem it will be necessary to interpolate; for instance say the mean effective pressure is 40 lb.; it would be necessary to add 20 per cent. to the horsepower reading, or use 290 instead of 242. If the mean effective pressure is greater than 50 lb. the rating would be reduced.

From the rating above found read to the right to the heavy curved line designated as 500 ft. per min. piston speed, thence down to the cylinder-diameter scale and read 20¼ in. diameter of cylinder.

By reading up from the scale indicating the length of stroke in inches to the 500-ft. piston speed, the number of revolutions per minute of engine may be determined. From the group of lines indicating mean effective pressures the per cent. of cutoff required for a particular initial pressure may be found.

Suppose a mine superintendent has an engine of known diameter and stroke; he also knows approximately the steam pressure available and wishes to ascertain the range of volume and pressure under which such motive power would be effective.

The number of revolutions per minute and stroke combined will give the piston speed. The diameter combined with the piston speed will give the horsepower for a mean effective pressure of 50 lb. per sq.in., and by interpolation this figure may be changed to correspond with any mean effective pressure.



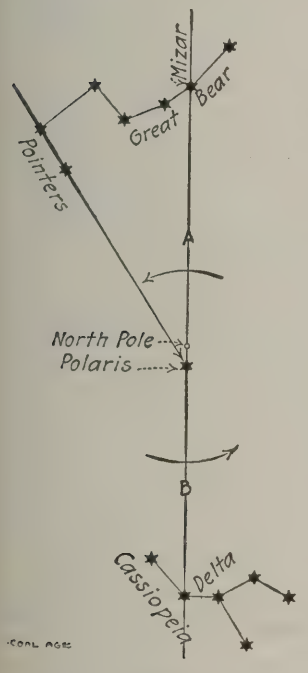
The horsepower once determined, it is only necessary to reverse the operation previously described to read the water gage at which the determined horsepower will deliver various quantities of air.

The scope of this chart does not take into account any features of the fan other than to assume that it operates with a mechanical efficiency of 62½ per cent.

Cleaning Commutators

Cotton waste should never be used for cleaning a commutator, as the loose threads are liable to be caught under the brushes or by the commutator segments. Commutators should have a smooth, dark glaze. When slightly roughened they may be polished with a small amount of vaseline and a little No. 00 sandpaper fastened to a block especially made to fit the curved surface. For a greater roughness coarser sandpaper is effective, but if the roughness is very pronounced and ridges have developed, the commutator should be turned in a lathe.

It is well to apply a little vaseline to a commutator in good condition. Avoid the use of emery cloth. It contains iron and is therefore a good conductor of electricity; hence it is liable to short-circuit the current through adjacent segments. Vaseline is superior to clear oil as a lubricant of commutators. Too much vaseline, however, will give a dirty black appearance and will cause sparking.—*Employees' Magazine.*



Is This Benign Old Gentleman Turning into a Shylock?

Method of Obtaining Time and Azimuth

By J. A. Macdonald*

The usual method of obtaining the azimuth from Polaris is by making observations at elongation. While the following method is not new, it is not generally known and will be found much simpler in application and fully as accurate as the elongation method. No instrument is required and no nautical almanac or mathematical tables are needed.

This method is based on the fact that Polaris and two adjacent bright stars are in the same vertical plane only a few minutes before Polaris crosses the meridian. It can be used at only one moment in each 24 hours and it requires a fairly clear sky to enable the stars to be sighted behind a plumb line. The two stars that can be used in this observation are Mizar, the middle star in the tail or handle of the constellation known as the Great Bear or the Dipper, and Delta in the constellation Cassiopeia , commonly known as the Little Dipper. The former can be used only when it is below the pole during the night. When it passes the meridian above the pole it is too near the zenith to be of service, in which case the latter star is observed.

Showing Mizar and Polaris on Meridian

The accompanying diagram shows the principal stars of the constellations of Cassiopeia and the Great Bear with Delta Cassiopeia, Mizar and Polaris on the meridian. The following tables show the exact time at which these stars are in the same vertical plane on given dates. The time for other days can be secured by direct interpolation, the daily variation being four minutes. From January to June the observation is made with Mizar, and from July to December with Delta Cassiopeia.

	On line.		On line.
January 20	5.22 a. m.	July 20	5.30 a. m.
February 20	3.20 a. m.	August 20	3.28 a. m.
March 20	1.30 a. m.	September 20	1.26 a. m.
April 20	11.24 p. m.	October 20	11.24 p. m.
May 20	9.26 p. m.	November 20	9.22 p. m.
June 20	7.24 p. m.	December 20	7.24 p. m.

When it has been determined by observations that Polaris is in the same vertical plane with one of these stars it can be shown that it will pass the meridian 7.15 minutes later during 1913. This interval is increasing from year to year at the rate of 0.33 minutes so that in 1914 the interval will be about 7.5 minutes. The observation can be made either indoors or out by suspending an ordinary plumb line and marking the direction of the meridian by setting a second point at the stated interval after the two stars are in the same vertical plane.

The same observation may be used to determine local standard time by the use of the accompanying tables for time, adding four minutes for each degree if the place of observation lies west of the time meridian and subtracting the same for stations east of the meridian.—*Railway Age Gazette.*

The Mine Mule

By J. W. McCabe*

Some people believe that a mule should always be fed as much as he will eat, and have both hay and grain in the manger all the while he is in the barn. Thus no change in his allowance is made whether he works every day or only three or four days a week. The failure to reduce rations with due regard to the time the mule is idle not only tends to increase the cost of maintenance, but is harmful to the health of the animal. The excess hay will be scattered under his feet and wasted and the grain will accumulate in the bottom of the feed box, where it will soon become sour. This bad grain will surely hasten the mule into poor health by causing indigestion. Thus when starting to work, after several days' idleness, the mule naturally develops spinal meningitis or some other serious disease.

How Much Food a Mule Should Receive

A much better way to feed the mule is to give him, during working days, only as much grain as he will eat up clean at each meal. At no time should any more hay be given than he will consume in his one meal at night. A safe rule by which to be guided, with slight variations to suit individual requirements and local conditions, is as follows: One pound each of hay and grain per day for one hundred pounds of flesh. For example: A 1000-lb. mule should be fed 10 pounds of hay and 10 pounds of grain per day. When the mule is idle and is having little or no exercise, the amount of hay should be increased and given twice a day, and the grain ration should be reduced from one-third to one-half, according to his physical condition.

When the ration is composed of corn, oats and timothy hay, without a mixture of nice green clover or alfalfa hay, about one-third to one-half pound of wheat bran should be fed daily, in addition to the above mentioned grain ration. Plenty of good water should always be kept accessible in front of the manger.

Keeping all roads and cars in good condition will add considerably to the comfort of mules, as well as help a great deal toward keeping them in good shape. A sick or crippled mule cannot work and is therefore a dead loss to the company while under the doctor's care.

A mistaken idea which seems to prevail among many drivers and assistant foremen is that in order to secure the best results from a mule while at work, it is necessary to hurry him. Frequently their only reason for this haste is that they themselves may have more time to rest at the bunk, and in order to gain this little extra time, the mule is often overloaded and seriously abused. Some mules will submit meekly to this hard treatment. Others, having strong minds of their own, refuse to permit it and resort to their ever-trusty heels for self-protection; and when the cry goes through the mines, "Another mule has gone crazy," do you wonder why?

Note—From the "Employees' Magazine," January issue.

Gasoline Industrial Locomotive

By S. T. Nicholson*

SYNOPSIS—A general summary of the industrial railway field with particular attention to the mine tramway. A short description is then given of the Vulcan gasoline locomotive, which has successfully met the exacting conditions of underground service.

Long before the advent of gasoline, electricity or compressed air as factors in transportation, a well known railroad man was heartily ridiculed by some of his fellows at one of the early steam-railroad conventions. His mental acrobatics had been of the prophetic sort. He had been sufficiently ambitious to suggest that less than a quarter of a century would find sources of power other than steam as active agents in transportation.

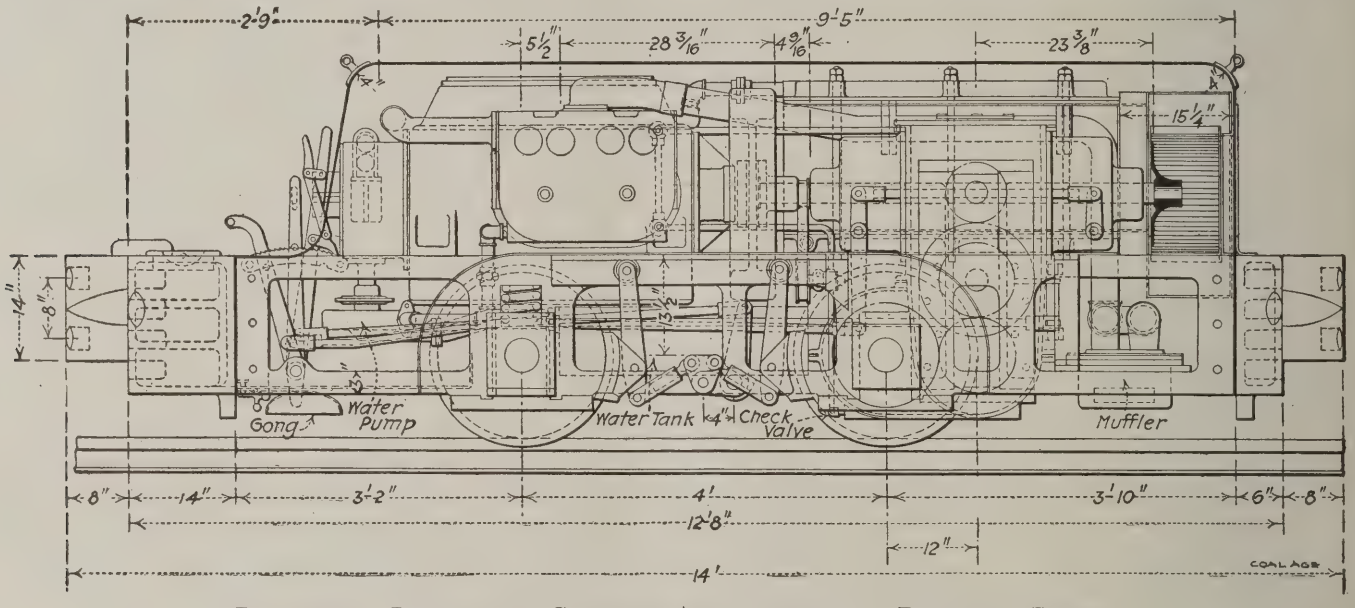


Diagram of Locomotive, Showing Arrangement of Principal Parts

The way of the world has been thus from time immemorial. Yet when a new force or a device hitherto unknown is brought out, when it has passed through its experimental stages, when it has reached the point where its components can be subjected to standardization, and, finally, when it has established a record for commercial success, we have a new economic factor, another power affecting the price of the world's goods.

Locomotives Are the Result of Evolution

The gasoline locomotive is simply another example of the usual process of evolution. Like the steam-actuated tractor, its forerunners were and are still in a much augmented and highly developed form, highway vehicles propelled by a similar force and largely in a similar manner. Steam road wagons with crude upright boilers and unrefined engines preceded the locomotive by many decades. The incongruities of their construction rendered them commercially impossible; the limited knowledge of their day prevented their becoming economic factors. Nevertheless the application of their principles to machines traveling on rails has proved highly successful, and the steam locomotive for the last 80 years perhaps has been an enormous economic power.

That the use of gasoline in railroad work fell short of keeping pace with its utilization for road vehicles—automobiles—has often been a source of wonder; but recent applications of highly developed, standardized gasoline locomotives in industrial transportation have indicated their successful economic usefulness in certain fields where steam locomotives are either impracticable or impossible, and where the cost of electric or compressed-air operation and maintenance is usually incommensurate with the profits of the business.

Comparatively large gasoline locomotives are at present used in standard-gage freight-switching service in some parts of this country and Europe. Their work has been satisfactory, and they are undoubtedly embryonic forms of larger and more flexible future units. Nevertheless industrial railroads and more specifically mine tramroads seem to be of the nature to which such locomotives are best adapted.

Until means are at hand by which internal-combustion locomotives can be produced in a form that can compete with the steam-actuated machine, their development for industrial purposes is of greater interest and somewhat more timely. It is immediately apparent, however, that the gasoline locomotive is in the strict sense a locomotive, not an automobile, and that it requires a locomotive builder to produce it successfully.

The Gasoline Locomotive Is Self-Contained

Like the steam locomotive, the gasoline machine has the fundamental advantage of being an independent, self-contained unit. It has also the additional advantages which are especially potent on industrial railways and in mines, of being less dependent upon a copious supply of water, and absolutely divorced from the coal pile.

Of course, weight is an important element in any tractor, for without it a large pulling effort is unattainable.

*Wilkes-Barre, Penn.

Weight, however, is of two varieties, useful and excess, and as the pull of any tractor is a question of engine power, diameter of drive wheel and several other factors, it follows that the elimination of excess weight (in the case of the steam locomotive a boiler three-quarters or more full of water, and a coal supply of from one-half to two tons) will increase the locomotive efficiency by lowering the center of gravity, reducing wear on the track, and so far as the engine is concerned, transform a relatively greater amount of the power generated by the internal explosion into useful mechanical motion than the steam driven machine can of the heat generated from the coal pile.

Granted that these conditions are true, the efficiency of this type of locomotive will be high. Consequently, its economic status is immediately established, since higher efficiency simply means getting a greater return on a given investment.

There are certain inherent characteristics in any design, even in the underlying principles, of any type of present-day gasoline locomotive which limit its usefulness as a machine of general utility. As those which have attained commercial success stand today, they are essentially slow moving, heavy-duty machines. The form of construction that is generally followed is not conducive to high speed, nor are high speeds desirable on industrial railways.

We therefore arrive at a highly specialized locomotive, capable of developing its greatest power under the most desired or rather the most generally existing conditions. The average industrial or mine locomotive is expected to exert its maximum draw-bar pull on a rough, light track with many curves, some of which are extremely sharp, severe grades, and uncompensated curves on gradients at speeds of from 4 to 12 miles per hour.

Typical Conditions of Operation

A typical case illustrating the conditions with which this form of tractor frequently has to contend is shown in the report of operation of a six-ton Vulcan gasoline locomotive at a mine of the Righter Coal & Coke Co., at Lost Creek, W. Va. Here the conditions of operation absolutely eliminated steam locomotives—although steam-storage or compressed-air machines might have been acceptable if clearances had been greater—and the great cost of an electric system with its danger due to the arcing of the trolley wheel, the sparking between the commutator and brushes and the lack of headroom for the trolley wire precluded electricity also. The report of the demonstrator at the Righter Coal & Coke Co.'s mine is clear and brief, covering the entire situation.

The locomotive works inside the mine, hauling loaded cars from a branch road to the top of the plane over 25-lb. rails. Empty cars are handled on the return trip. The track is uneven and the undulations present grades varying between 1 and 2½ per cent., there being practically no level track. The distribution of grades is about equally favorable and unfavorable to loaded movement. Curves are sharp and frequent.

The weight of the empty cars is about one-half ton each, while the loaded weight is about three tons per car. Fourteen cars have been hauled on a single trip, although the average is 12. The locomotive however has demonstrated that it could handle 20 cars easily, were the capacity of the branch track great enough to hold this number. This is computed on the basis of the above loaded weight per car and a hauling capacity of 64, 42 and 34 tons on grades of 1, 1½ and 2 per cent.; respectively. The locomotives rated tractive effort is 2400 lb., which enables it to haul 114 tons on a straight and level track with frictional resistance figured at 20 lb. per ton.

The length of run from stop to stop in 1800 ft. with a running time of 1¾ minutes. In the average nine-hour day, 275 cars or 30.55 cars per hour are hauled.

This work requires 10 gallons of gasoline, or 0.9 gallon per hour, the equivalent in cars being 27½ per gallon. The quality of gasoline used costs 16c. per gallon, but a better grade with probably a higher heat content can be had for 20 cents.

On the 16c. basis this would place the cost of hauling 275 cars or their equivalent 481¼ short tons at $1.60 per day, or about ⅓c. per ton for fuel only. Of course, interest on the investment, cost of track, car and locomotive maintenance, lubricants and labor, as well as the absence of earning power of the locomotive when the machine is not in motion must be added to the fuel cost before the final expense can be determined. But with the fluctuations of these values in various localities it is simple to estimate the cost on any specific railway, and furthermore, these figures point conclusively to the locomotive's dividend-increasing ability.

Time-Tried Characteristics Are Retained

Quite naturally locomotives of this type can be built in varying sizes and made to incorporate special features

External Appearance of Locomotive

that will enhance their value in specific kinds of service. As a general rule, however, they follow a definite principle and retain as many of the time-tried characteristics of steam locomotives as possible. The cast-steel frames with their pedestal jaws, shoes and wedges and binders are familiar; driving boxes, brake and spring rigging hold to the old form also, except where structural differences make alterations obligatory.

The essential features are a four-cylinder, four-cycle, double-opposed gasoline engine, bolted direct to the frame; a driving shaft with flywheel connected to the transmission shaft by universal joints and delivering power through two multiple-disk clutches. Between these clutches is a train of bevel and spur gears for driving the jackshaft. The rear or main drivers are rotated from this latter through case-hardened spur gearing and transmit their energy to the forward drivers in the usual manner. The gears run in oil and are inclosed in an oil- and dust-proof case.

The magneto is gear driven from the engine shaft. The cylinders are water-cooled and circulation is maintained by a large centrifugal pump. Almost the entire section over the front drivers is devoted to cooling tubes, and these are aided by a large multi-bladed fan mounted on the engine shaft. The entire design savors of great care and thought and a thorough acquaintance with the best gasoline practice.

There is little reason for going deeply into the structural details, since the accompanying diagram, shows the general arrangement clearly. Some features, however, rather more of an engineering and operating than of a structural nature, combine good, common engineering sense with the idea of saving money.

The Machine Is Designed for Hard Usage

It is clear that the designer must have had the rough treatment and hard usage of the mining regions in mind when he put a rugged and foolproof machine on paper. Three points insignificant in themselves are upon second thought among the best economic features embodied in the Vulcan locomotive. The cylinders are horizontal and double-opposed instead of vertical, since in this way the opposite pairs of pistons neutralize the thrust on the crankshaft and the horizontal plane of the cylinders does not encroach on the limited head room.

Another point is found in the change gears, where two integral jaw clutches take the stress of shifting, leaving the gears always in mesh. The strong point of the arrangement is in the placing of the jaw clutches on the high-speed engine shaft, with accessories that lock them in position when the multiple-disk clutches are engaged. It follows, consequently, that the transmission is relieved of all strain when speeds are changed.

The method of reversing the locomotive is novel in that it is done entirely through the two multiple-disk clutches. The process, however, could not be simpler, and is less laborious than reversing a steam or compressed-air machine, for throwing a lever to the rear engages the rear clutch, while moving it forward engages that for forward motion. At the neutral point both clutches are disengaged and the locomotive is stopped.

For convenience in operation the brake, change-speed and sand-box levers are placed on the same shaft as the clutch-reverse lever. With this arrangement, the consequent ease of control is a close approach to effortless labor.

The keynote of design in this locomotive is simplicity; that of its operation, economy plus ability and efficiency. There are, of course, many small points of refinement that are extremely interesting, while the results thus far achieved make it a formidable economic factor. The full report of its operation, cost (maintenance and otherwise), and its economic effect on mining and industrial railways are valuable contributions to the art of industrial railroading.

Reasons for Opposing Anthracite Tax

The bill in equity of the Peoples' Coal Co. of Scranton against the enforcement of the new 2½ per cent. anthracite tax by Archibald W. Powell, auditor general, of Pennsylvania, and Robert K. Young, state treasurer, will be argued in the court of common pleas for Dauphin County within a few days. The Peoples' Coal Co. avers that the act imposing the tax is illegal in eight different ways and as illogical as it is illegal.

The first legal objection to the act is that it is a local and special enactment, and no notice of its passage or proposed passage was given as should have been done according to Article 3, Section 8, of the Constitution of Pennsylvania.

The second legal objection is that the tax violates Section 1 of Article 9 of the State Constitution which provides that all taxes shall be uniform upon the same class of subjects within the territorial limits of the authority levying the tax. Anthracite coal differs from bituminous, semi-bituminous, and semi-anthracite coal in no wise except in the percentage of fixed carbon contained in it, and the line of demarcation is so slight, and the uses to which it is put, so similar as to make any attempt to separate it from other coal, as a subject of taxation, arbitrary, illogical and illegal. All the coals mentioned are mined within the limits of the state of Pennsylvania which is the authority imposing the tax.

Tax Will Go to Townships Where Coal Is Not Mined

The third legal objection to the tax is that it violates the elementary principle of taxation, which requires that its purpose must pertain to the district taxed, and this objection also covers the illogical features of the distribution of the proceeds. The result of the distribution of one half the proceeds to the boroughs and townships of the various counties where coal operations are carried on, pro rata according to their populations, as specified in the act, would be that many boroughs and townships would receive large sums of money from this source when, as a matter of fact, not a pound of coal of any description is produced within their limits.

It is pointed out that if this act were enforced, a number of municipalities in the county of Lackawanna for instance would receive amounts two, three, four or five times as great as their municipal expenditures, though these municipalities do not produce a pound of anthracite or of any other kind of coal. Dalton and Waverly boroughs and the townships of Benton, Covington, Greenfield, Jefferson, Newton, Scott and South Abington, of which the above is true, would receive an estimated aggregate of nearly $20,000. This would result, on the other hand, in only a small amount being appropriated to the municipalities producing the coal.

The fourth legal objection is that the bill is contrary to Article 3, Section 3 of the Constitution of Pennsylvania which provides that only general appropriation bills, may contain more than one subject, which must be clearly expressed in its title. The bill in question provides in its third section that the failure of the operator to furnish reports shall constitute a misdemeanor, punishable by fine and imprisonment, thus introducing a new crime into the criminal code of Pennsylvania without a word in the title of the act to give notice of any such purpose or intention.

Also Violates United States Constitution

The act is also alleged to violate two provisions of the Constitution of the United States. Anthracite is an article of interstate commerce, and Article 1, Section 8 of the United States Constitution provides that Congress shall have the power to regulate commerce among the several states. Furthermore, the Fourteenth Amendment to the Constitution provides that no state shall "deprive any person of life, liberty or property without due process of law."

The act is said to be contrary to Section 18 of Article 3 of the Constitution of Pennsylvania, inasmuch as

it undertakes to distribute as a gratuity to certain communities large sums of money, assessed and collected by the accounting officers of the commonwealth as state taxes, said communities being in no special manner entitled thereto, because the subject matter of the said tax is not situated within their limits. The act contains two distinct and diverse subjects, not clearly expressed in its title, i.e., the provision for raising revenue by taxation and the appropriation of state funds, raised by this taxation, to various municipal corporations. This is an additional violation of Article 3, Section 3 of the Constitution of Pennsylvania.

The Explosion at Ravenwood, Colo.

By Samuel Dean*

SYNOPSIS—This accident seems to prove the efficacy of shale dust as a preventive of widespread coal-dust explosions. It is stated that shale dust is not likely to cause lung troubles. Much depends on having dust-tight cars.

A small explosion, causing the deaths of two men, the result of a blown-out shot of permissible powder (Monobel No. 3), occurred at the Ravenwood mine, near Walsenburg, Colo., on Jan. 17, last.

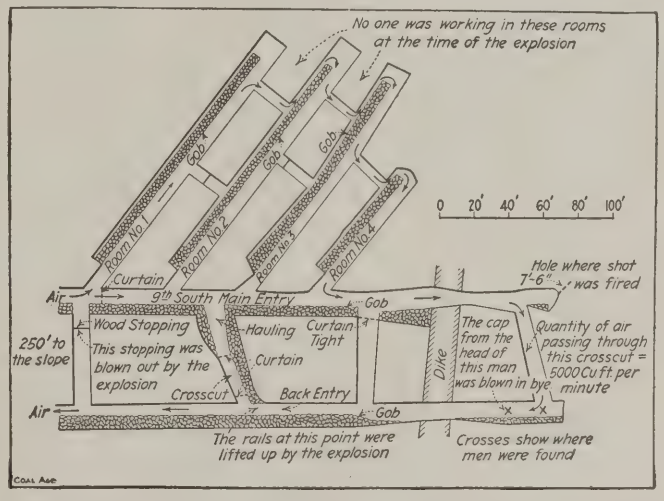
It appears that the two men were working at the face of the main ninth south entry just off the slope, and had drilled a hole 7 ft. 6 in. deep into the solid coal. Several sticks of Monobel had been seen by the driver near the face before the hole was charged, and the assumption is that the men inserted a quantity of powder which was beyond the charge limit (1½ lb.). Circumstances point to the fact that after lighting the fuse they passed through the last crosscut near the face into the back entry to avoid the concussion of the shot.

The shot, quite naturally, blew out, starting a dust explosion, and both men were afterward found dead in the back entry opposite the last crosscut. There had evidently been much flame as both bodies were badly burned.

Evidence Points to Disobedience

A shotfirer is provided at this mine (which is worked with open lights), and one of the rules is that no holes shall be charged or fired before all employees, excepting the shotfirer, are out of the mine. Miners are not supposed to have any blasting caps in their possession. These two men, who directly caused their own deaths, had procured caps, and their probable intention, in drilling this deep hole, was to fire what is called a cracking shot.

The shotfirer fires, on the average, about 45 shots a night; the majority of these being brushing shots. The rules do not authorize him to charge or fire holes in the coal unless the coal is sheared or undermined.



At the time of the explosion (between 12 noon and 1 p.m.), there were 92 men in the mine. And the reason why the explosion did not propagate over a larger area was that there was a quantity of shale dust lying in the entries, which became mixed with the coal dust. This quenched the flame and caused the explosion to die out before reaching the slope.

The shale dust is formed naturally. The coal is only 2 ft. 8 in. thick, and 2 ft. of the top and 1 ft. of the bottom are brushed. Much of the shale from the brushing is gobbed along the sides, and in addition to what is left on the floor, pieces fall down and are crushed by the wheels of the cars and the feet of men and mules.

*Delagua, Colo.

Men in other parts of the mine felt the explosion and hurried out to the slope. A driver standing on a parting on the north side had his cap blown off his head. Some little time elapsed before officials were able to penetrate the ninth south entries on account of smoke and afterdamp.

Back from the faces, and where the explosion stopped, the entries were perfectly dry, and dust on the ledges

Underground Plan of Ravenwood Mine with Descriptive Notes

could be blown away into the air-current. No one in the mine, as far as could be learned, noticed any counter-currents or inrushes of air. But it is quite easy to understand that the minds of people would not be in a condition to make scientific observations at such a time. It was quite plain that there had been an inrush of air toward the faces, but whether this had occurred as the explosion was dying or had opposed the explosive wave when at the height of its power, I am unable to say. However, it may be found to be an easy matter to arrange different apparatus in an experimental mine to prove, or disprove, the "counter-current" theory.

Analyses of the Dust

After the explosion, samples of dust were swept from the floor and sides of the ninth south entry. The following are analyses of the dusts:

	No. 1 Sample Per Cent.	No. 2 Sample Per Cent.	No. 3 Sample Per Cent.
Moisture	6.51	6.19	2.95
Volatile matter	17.08	19.89	19.78
Fixed carbon	42.79	51.98	50.78
Ash	33.62	21.94	26.49
Total	100.00	100.00	100.00

Sample No. 1 was gathered at the face of the ninth south main entry, from around the hole which was shot.

Sample No. 2 was taken from rib opposite crosscut, which measures 12 ft. from face of main entry.

Sample No. 3 was gathered off the roadway from between the rails, at different places, all from within 14 to 20 ft. of face of main entry.

Samples taken further outby on the entry, where there had been more traffic, would have shown a larger ash content. From appearances there was at least 50 per cent. of shale dust in the dust mixture where the explosion stopped.

The following table shows the barometer readings on the day of the explosion, and a few days previous:

Date	Time, Bar.	Time, Bar.
January 14	9 a.m., 24.20	3 p.m., 24.06
January 15	9 a.m., 23.93	3 p.m., 23.84
January 16	9 a.m., 23.92	3 p.m., 23.85
January 17	9 a.m., 23.86	3 p.m., 23.84

This may be an opportune occasion to say a few words regarding the application of incombustible dusts, which are used for the purpose of preventing or stopping explosions of coal dust.

Shale Dust versus Water as a Preventive of Coal-Dust Explosions

A number of water-treated mines have "blown up" violently, causing hundreds of deaths, within the last two or three years, with the result that an increasing number of mining men are giving the use of "stone dust" attention.

To begin with, it may be said that, the terms "rock dust" or "stone dust" are not satisfactory. They give the impression of dusts which are hard and gritty. Shale dust is more suitable, but several different dusts can be used with success, and without any apprehension as to dangers arising from breathing or swallowing them. Boiler-flue dust, or the light brown dust called ash is now being used and is giving satisfaction. It has been found, after a number of years of practical experience with dusts in coal mines, that they are not likely to cause lung troubles.

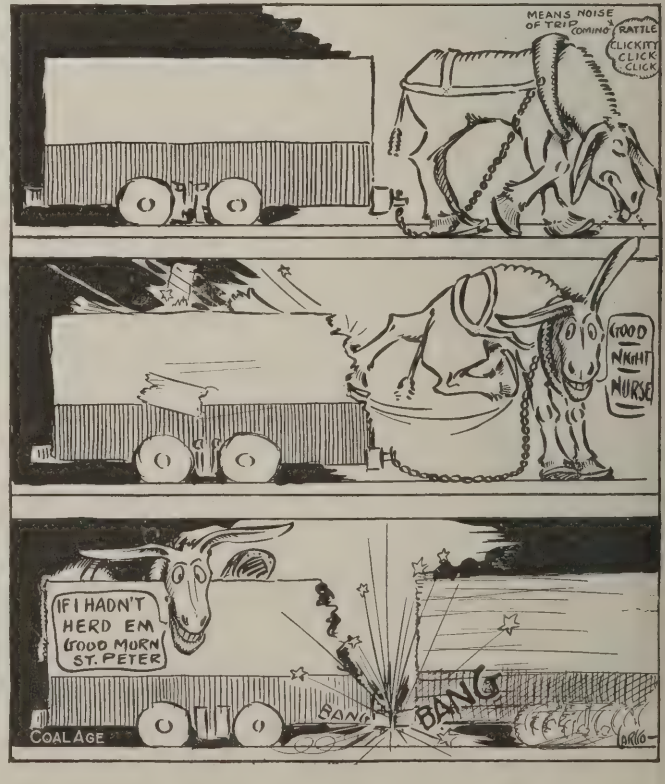
In place of the term "rock dust," we might use "incombustible dust," as suggested by W. C. Blackett; this covers all the different dusts that are suitable for the purpose.

Where it is proposed to use an incombustible dust, the writer wishes to urge strongly that the applications of dust should be plentiful. It is also important that the man who has charge of the installation of this preventive should be enthusiastic about its merits. It would be very unfortunate to have it applied in such an inefficient manner that an explosion would travel through a treated roadway.

Application of Incombustible Dust Is Not Costly

The efficient application of incombustible dust is not costly. But it is expensive to maintain clean roads in mines where poorly constructed wooden end-gate cars are used, and the coal is soft and friable. Should small coal and coal dust be allowed to accumulate on the roads and exceed the amount of incombustible dust, then a widespread explosion would be possible, and the money spent in "shale dusting" will then be thrown away. In addition, in the event of an accident, this method of prevention would probably receive a condemnation which was not deserved.

In my opinion, the best thing to do first to combat the coal-dust menace is to install rotary dumps. Then set the carpenters to work bolting down the end doors, and making the cars as dustproof as possible. Where crossover dumps are used, the cars are often not completely emptied, and coal is not only sprinkled along the roads by the loaded trips coming out, but also by the empty trips going in. All new cars should be tight, and preferably built of steel. Road cleaning and shale dusting can then proceed and will certainly produce valuable results.



It is practically impossible to keep a mine free from the minimum quantity of dust necessary to propagate an explosion, and the weight of incombustible dust required should be governed by the amount of coal dust present.

Of course, the introduction of all these safety precautions, which we hear so much about, must of necessity be governed by the margin between the cost of production and the selling price. And this margin is smaller in the United States than in any other part of the coal-mining world.

At the coroner's inquiry into the recent explosion at the Vulcan mine (Colorado), the chief state inspector said that he had been unable to carry out the law on account of a lack of funds. It is difficult to imagine a more ludicrous situation—a government inspector unable to carry out the law because the state was short of money. Should a coal operator make any such plea, he would probably be compelled to go out of business.

Some Sagacity!

Many mules have been killed by runaway cars and by the carelessness of trip-riders in sending blind loads down entries and slopes. The sketch below indicates how a W. Va. mule took care of himself and utilized the only means of escape.

The Du Bois, Penn., Convention

SYNOPSIS—Patrick Gilday advocates fines for violation of agreements. The miners are anxious to start co-operative stores.

On Tuesday, Feb. 24, the convention of District No. 2 of the United Mine Workers of America met in the Avenue Theater, at Du Bois, Penn., Vice-President James Purcell presiding. The President, Patrick Gilday, was unable to be present owing to illness.

Passing over minor matters, we come to the report of President Gilday read on his behalf by Charles O'Neill. We wish to compliment him on the boldness of his open advocacy that violations of the agreement between miners and operators be made a matter of penalty. Our readers will remember that this was one of the six demands made by the operators at Philadelphia, where District No. 2 was not represented.

Difficulties in Assessing Fines

This proposal is undoubtedly fair but it is hard to enforce against the operators because no one can tell why they suspend individual men or lay off all their employees whether because of union activity or to promote efficiency or from lack of market to keep their mines running.

It is equally difficult to make such a provision operative against the mine workers because of the poverty of the union and its failure to incorporate and also for the reason that there are so many ways of avoiding an open violation of the terms of the agreement. Unduly protracted holidays may be mentioned as means of creating the effect of a strike without perhaps a violation of the letter of the contract.

Will Public Opinion Favor Even a Fair Scheme?

However, the experiment may be worth trying and the result might prove wholly beneficial even if far less completely effectual than it would appear to be on its face. We cannot say that we are extremely hopeful. The system is one of fines and while it works both ways it has an unpleasant similarity to a practice in certain mercantile establishments and factories of fining those who are guilty of infractions of rules of the house. This practice has died out in America largely. Its existence was marked by no little friction.

Mr. Gilday stated that operators and miners had broken their agreement. We are somewhat disposed to think this true. Of course, it will be readily acknowledged as of force with regard to the mine workers because otherwise why is it acknowledged by their spokesman. Besides everyone knows it is true.

The Claim that Operators Break Agreement

On the other hand, the mine-workers claim that any action taken by the operators to prevent bosses from joining the Union is in violation of the agreement. The operators did not expect to face unions so aggressive that even the bosses would be induced or compelled to join. In former days the tendency was rather toward "class," than toward "industrial unionism" and bosses were considered proper members of a union of their own and were not wanted in the United Mine Workers of America where the other members feared their presence would be a menace rather than an assistance. On the one hand, they might have been disposed to use undue influence and on the other hand to spy for the benefit of the operators.

Consequently, the agreement tacitly overlooks officials of all kinds. If, however, the contract reads so as to bind the company with regard to these men, the operators cannot excuse themselves in breaking it by loosely stating that they did not have it in mind when they signed the agreement. Nor can they excuse themselves by saying that exclusion is reasonable and should be incorporated in the contract. It is only proper that such a proviso should be made just as proposed by the operators at the Philadelphia Conference but this fact would not justify the employers in slipping in a new clause, however righteous, into a contract to which they had already appended their signatures.

The Contract to Be Read in Light of Past Practices

But does the contract so bind the operator. The agreement clearly provides for increased wages for "monthly men" and so possibly in verbal strictness even general managers and vice-presidents may be included. As a matter of actual fact and usage, we believe the companies rarely advanced bosses in accord with the changed wage scale and the union, not regarding these men, as of their own kin made no objection. The agreement is to be read according to the "law merchant," if we may be excused the expression. The actions of both union and operators have been such as to show conclusively that neither party hitherto regarded bosses as subject to union agreements and the meaning of the contract is to be judged by the customary practices in the industry.

The contract applies to all, union and nonunion men, who work for the corporations under the schedule whether their particular employment is named or unnamed but it does not have any bearing on those whom long practice has exempted from the operation of the agreement whether they join the union or not.

Excluded from the benefits of the wage scale because they are bosses, how can they be made to be covered by the contract for the sole purpose of maintaining the unrestricted right of the union to enlist new members. They are either in the contract or out of it, being unnamed. If they are not in the wage scale they are also not in that part of the agreement relating to the noninterference with union activity.

Do Operators Ever Try to Break Contract?

Though we cannot feel that the exclusion of bosses is a violation of the contract, there is probably some truth in the statement that here and there the operators have shown a disposition to break, and in some cases may have broken, the contract. In most cases, however, the situation is like that arising out of the Panama treaty and results from a variant interpretation of an agreemnt signed without due consideration.

In a neighboring district, a man who is as well disposed to laboring men as we are likely to find, wanted to violate the scale agreement, as he related at the Coal Mining Institute of America, and he probably would have taken up the fight to break it, had conditions favored. He was introducing a better system and new machines in his

mines which he declared at the institute enabled two men to undercut 447 tons of coal per day instead of 200 as before. He wanted to provide that those men would earn nearly a half more pay than they were getting but to reduce at the same time the rate per ton paid them. The new machine men were to get 7c. per ton, the old cutter and scraper got 11c.

The union demurred; there was the scale already signed and it would have to stand till the next convention and conference. But the scale will remain just as it was—a deterrent to all who would otherwise scrap their older types of machines and discontinue their more antiquated methods of operation to the advantage of the worker, the consumer and the enterprising operator. We introduce this as an evidence of attempts to change the scale, some of which, however, are not marked by any such ample reason.

Consistency in accepting the scale, good or bad, logical or illogical is to be urged without reserve on all parties and a court to interpret its meaning is much needed.

Fines Involve a Court

The fines proposed lead us inevitably to a board of conciliation and arbitration for without a court how can fines be assessed? And so Patrick Gilday appears to be ready to accept another principle demanded by the operators at Philadelphia. One advantage of such a body would be that it might be given broad powers which would permit it to take under consideration questions of remuneration where a new device assures the workman increased productivity. As a further advantage the arbitral body would place equal burdens on all in a district and make inequalities in interpretation of the wage scale impossible.

Patrick Gilday further recommended that the union give scholarships to young men entering State College. He recommended the mine workers to remain at work after Apr. 1, pending the outcome of the deliberations provided the conference between miners and operators was then in session.

The District Union Had $2.57 per Member Jan. 31

The membership in the district union increased during the past year from 32,755 to 37,993. The highest figure reached was in 1910 when it was 38,649. The total receipts for the year including the previous year's balance were $463,455.14. The expenses were $365,-624.82, leaving on hand, Jan. 31, $97,830.32.

On the second day, a resolution was passed recommending the international president to withdraw the national organizers from district No. 2 and send them to nonunion fields. A resolution was adopted authorizing the district officers to start a wholesale store so that local unions which start coöperative stores may buy their goods at wholesale prices.

Coöperative Stores

We hope that some attempts may be made in this direction. Nothing like capitalism in the union will tend so speedily to convert its members into the friends of capital. If, however, the unions should prove able to undersell the company stores, then these are doomed and few would regret it. This, however, is unlikely and the experiments of the unions in this as well as in benefit associations will broaden their viewpoint as to all forms of capitalism.

Resolutions were passed providing for the disciplining of delegates found under the influence of liquor, instructing the subdistrict officers to see that every mine has first-aid supplies always on hand, commending President J. P. White for not accepting the seventh vice-presidency in the American Federation of Labor and recommending that wires, motors and electric pumps be taken out of mines where dangerous gas exists. Other resolutions offered provided that checkweighmen pass an examination, that companies be required to pay the union for all unchecked coal coming from the mine, and that benefits continue to be paid for two weeks after a strike.

Coal Mining Safest of Big Industries

For the last quarter of a century the news of occasional mine disasters has been given prominent display in the newspapers of the land. In addition to these news displays, there have been reports now and then of serious mine accidents in Europe and Australia. The result has been that the general public now has the impression that mining is the most dangerous of all occupations. But this is not true.

Recently the casualty statistics for persons employed in coal mines, on railroads and in steel mills of the United States, in the year 1911, were assembled for comparison. The year 1911 was taken as a basis because that was the last year for which the Federal authorities had reports for all three industries. It was seen by the comparison that, for each thousand men employed, fewer coal miners were injured than railroad men or steel workers.

Bulletin 69, of the United States Bureau of Mines, shows that in 1911 the number of coal miners in this country was 729,279. Of this number 31,334 were injured more or less seriously. In the same year, according to the "Twenty-Fifth Annual Report of the Interstate Commerce Commission," the railroads employed 1,669,-809, and of this number 126,039 were injured. United States Senate Document 110, Sixty-Second Congress, bears testimony to the fact that 35,764 steel workers were injured of 158,604 employed.

A study of the figures contained in these government documents, shows that there were about half as many coal miners as railroad men employed and that less than one-fourth as many were injured.

It is also shown that, while the mines employed 570,675 more men than the steel mills, the steel mills injured 4430 more men than the mines did.

A reduction of the figures to a common basis brings out the fact that, for each thousand men employed, 42.96 were hurt in the coal mines, 75.48 on the railroads and 225.48 in the steel mills.

Editorials

Electric Winding Engines

Upon another page, under the caption "Types of Electric Winding Engines," by L. F. Mitten, we print an extremely comprehensive article dealing with the problem of slope and shaft hoisting. This clearly portrays the best practice along this line in American coal mines.

Having spent some years in charge of the design of hoisting machinery for one of the most reliable and successful firms in the United States engaged in the manufacture of this class of apparatus, Mr. Mitten is perhaps as well qualified to speak authoritatively upon this subject as any other man in America. We have no hesitation, therefore, in recommending a careful perusal of this article to such of our readers as are interested in hoisting problems.

Reversing Main Air Currents in Coal Mines

A paper presented by William Clifford, at the meeting of the Manchester Geological and Mining Society, held at Manchester, England, Feb. 10, 1914, and which will be published later in the *Transactions* of the Institute of Mining Engineers, draws attention to the need of reversing the main air currents in coal mines, under certain conditions and at certain seasons of the year, for the purpose of preventing the accumulation of ice in air shafts or in main hoistways used as downcast shafts.

The paper also describes briefly the arrangement of shunting doors for reversing the air current, so as not to destroy the uniformly curved lines of the expanding chimney commonly used when exhausting air from mines by means of centrifugal fans. Mr. Clifford was for a long period the agent for the Guibal fan in the United States. His device, in this connection, consists of a hinged door made to travel in channeled guides built into the sides of the chimney. In other respects, the arrangement of the shunting doors is similar to that used for many years, in the construction of the Beard-Stine fan.

In his paper, Mr. Clifford draws attention to a fact that has too often received insufficient attention; namely, the reduction of the intake area that often results from the accumulation of ice in the downcast shaft, or the main intake, slope or drift openings of a mine. The cold intake air quickly freezes any moisture that may be present in these intake openings. Mr. Clifford refers to this fact as being a chief factor in the explosion that occurred in the Harwick Colliery, near Pittsburgh, Jan. 25, 1904, in which 179 lives were sacrificed. Mr. Clifford states that the fan ventilating this mine was a Capell fan 13.5 ft. in diameter and 7 ft. wide, capable of producing 200,000 cu.ft. of air per min. and reversible, and that it had been run continuously as a blower, without change, for several weeks previous to the explosion, the weather in that time being severely cold. He adds that the accumulation of ice at bottom of downcast shaft had reduced the intake area at this point to 9 sq.ft.

In this paper, Mr. Clifford further draws attention to the important fact that before an air current can be reversed in a mine, the person responsible for its direction must have an intimate personal knowledge of the plan of the mine and the course of the ventilating current, and understand fully the effect that will be produced in respect to the flow of gas-charged currents, in different portions of the mine workings.

In this connection, we would refer readers to the valuable discussion that was conducted some time ago, in COAL AGE, Vol. 2, on the question, Should Mine Fans Be Built Reversible? The discussion extended from Oct. 19, p. 545, to Dec. 21, 1912, p. 880. Thirty letters were published, giving the views of men of large mining practice and varied experience. Although some arguments were presented adverse to the building of mine-ventilating fans reversible, the general consensus of opinion was that the greatest reliability, in respect to the ventilation of large mines, could only be secured by building the fan in that manner.

Mine Visitation

The danger attending the practice, too common in some districts, of permitting visitors to enter coal mines unattended and especially during working hours, has been again emphasized by a fatal accident that occurred at the National mine, Monday night, Feb. 23.

The victim in this case was Nelson Banchrost, 32 years of age, a marble cutter and resident of New York, who was engaged at the time on contract work in Scranton. He had been in Scranton but a week and had never seen the inside of a mine before. In company with several companions, Mr. Banchrost visited the mine and was lowered on the cage, to make a tour of the workings. After watching the miners at work in the chambers, they returned to the foot of the incline and watched the loaded cars going up and the empty cars coming down the plane. In a foolish attempt to cross the track, Banchrost was run down and so badly injured that he died the following night in the hospital, where he was taken.

No one will question the propriety of permitting visitors, at proper times and suitably attended, going into the mines to gain knowledge and experience, or it may be to satisfy curiosity, that they may understand better how coal is taken from Nature's great storehouse. However, mine regulations should be strictly enforced, forbidding irresponsible persons and persons unattended from exploring mine workings or entering the mine for any purpose whatsoever while the mine is in operation. Mine officials should be held to a strict accountability for any violation of these regulations.

It is common practice, in a large number of the anthracite mines, to permit no one to enter the mine without a duly certified pass, designating the time of the visit and the number of persons admitted, and requiring that the visitor be properly attended, although the company assumes no responsibility for his safety while in the mine.

This is as it should be. A mine is truly a dangerous place for one unacquainted with mining practice and conditions; especially during the busy hours of the day when coal is running and every passageway is an avenue of danger.

List of Fatal Coal-Mine Explosions

We publish, in the discussion department of this issue, p. 418, a letter from Prof. E. N. Zern, drawing attention to the difficulties surrounding the work of making a complete list of the fatal mine explosions. In referring to the admirable list of mine accidents, recently published by the Federal Bureau of Mines, Technical Paper 48, Professor Zern mentions a few mine explosions not included in this list compiled by the Bureau.

Since the publication of this accident list, which is properly limited to a fatality of "five lives lost in the accident," we also have noted numerous omissions of important explosions that have occurred in this country and which should be included in such a list. No one can fully appreciate the difficulty of securing a complete list of mine accidents, until he has attempted the work of compilation.

Some years ago, the author of Mine Gases and Explosions attempted to secure from the different state mining departments a complete list of mine explosions in which the fatality was limited to five lives lost and dating back only to 1896. Many of the replies received from the state departments, at that time, revealed the fact that no record had been kept of these fatalities, until very recently.

With a hope of eventually completing, as far as possible, the list of coal-mine explosions, both gas and dust, that have occurred in the United States and Canada up to the present time and that resulted in five or more deaths as a result of the explosion, either at the time or within a period of, say 30 days thereafter, COAL AGE proposes to publish at an early date a more or less complete list of such explosions.

To assist in this work, which will simply be carrying out the work already begun by others, we ask the hearty coöperation of readers and all others interested, directly or indirectly, in coal mining, to send us any information in their possession, or to make any correction or reference to such lists already published. This is a work in which all should heartily coöperate.

The Business Outlook

Although there are many who prophesy a more or less immediate return of the business activity so evident in the coal industry last summer, there actually seems to be little tangible evidence upon which to base such a prediction. It must be conceded that conditions are not normal, probably being at only about 65 per cent. of the average. The situation is particularly acute with the railroads, whose business represents about one-third of the total for the country. Under the pressure of adverse legislation, current reports show decreased earnings, and a generally straitened financial condition. The steel industry, which is closely affiliated with the coal business, has also felt the effects of the abnormal conditions keenly.

Probably one of the strongest optimistic arguments at the present time is the fact that the currency and tariff legislation have finally been enacted, and are now a closed issue, while this is further supplemented by the sanguine reports constantly emanating from Washington. It is also generally true that the economic condition of our country is much stronger than during the Cleveland administration in 1893, but there are many who will recall the disasters of that time with apprehension.

Improvements in mechanical devices, effecting a higher efficiency of labor, have made it possible to cope better with foreign competition; however, there has been but little time in which to prepare for this test which the country is now facing. There is some doubt also as to the practicability of the new currency legislation, although it is generally conceded that it will at least relieve the possibility of any panicky conditions, such as prevailed in 1907.

Without entering into the various merits of the issues now facing the government, it will be agreed that constant agitation must inevitably continue the policy of retrenchment on the part of capital. One cheerful feature of the current situation is the large amount of surpluses accumulating in the banks, awaiting opportunity for permanent investment. To this might be added the recent decision of the Interstate Commerce Commission, granting the industrial roads allowances which, it is said, will increase their revenue $15,000,000 annually; and it is also probable that the commission will ultimately permit a general advance in freight rates. These favorable developments have, at least, caused a feeling of cheerful hope in the conservative element of the business world.

As to the coal business itself, the indications are that anthracite, with its limited supply and close control, will have its customary profitable year. The outlook in bituminous, with its heavy over-production, and consequent keener competition is, of course, more susceptible to conditions in general industrial circles. The labor situation will be a potent factor in determining the ultimate results, and if there is a general suspension in the union fields for a period of six weeks or two months, it is reasonable to believe that a high price-level will prevail over the balance of the year, but with the heavy supply of coal now available at all the distributing centers, the reverse may be expected if this anticipated curtailment fails to materialize.

Prohibition in West Virginia

The mining industry of West Virginia is to be congratulated on the enactment of a state-wide prohibition law, which will take effect July 1, 1914. If this new measure is faithfully carried out, there is sure to be a noticeable improvement in the morale of the men in mining communities. Nothing has been more active in the destruction of character and prosperity in coal camps than the unrestricted sale of intoxicating liquors. Let the operators now provide moving pictures, playgrounds and baths, and the consequent reduction in lawlessness and enforced idleness will show up favorably on the cost sheets. But above all else will be the personal satisfaction and feeling of pride that must come to every man who lends himself to the work of fostering human happiness.

Legal Department

Mining Royalties Dependent upon Existence of Coal

By A. L. H. Street*

SYNOPSIS—The courts incline toward an interpretation of leases as exempting liability for rent or royalties where production is impossible or unprofitable, except where there is an express agreement to the contrary.

The law reports indicate that disputes frequently arise under coal-mining leases concerning the lessee's liability for rent or royalty as affected by exhaustion of coal or failure to find a merchantable seam.

A lease of land for the purpose of exploring for and mining merchantable minerals at a fixed annual rental has been declared by the Michigan Supreme Court to involve an implied understanding that minerals exist in the land, releasing the lessee from liability for rent, on it appearing that no minerals exist. (Blake vs. Lobb's Estate, 68 Northwestern Reporter 427.)

As was said by the Colorado Supreme Court in the case of Colorado Fuel & Iron Co. vs. Pryor, 57 Pacific Reporter 51, the parties to a mining lease are presumed, in the absence of express provision to the contrary, to have contemplated mutual advantages, and unless merchantable coal is found and can be produced at a reasonable profit the lessee is not bound to work the mine. The court accordingly decided that a lessor, in order to show himself entitled to recover on account of the lessee's failure to operate under the lease, was bound to establish not only that the land was underlaid with merchantable coal, but that it could be mined with profit after deducting the royalty.

Colorado Supreme Court Quoted

The court said: "The coal might be merchantable, and yet the lessee be unable to produce it at a profit, after deducting the stipulated royalty, which would be regarded as fair and reasonable for ventures of this kind."

But where a lessee made annual payments to avoid forfeiture of the lease for failure to mine, it was decided by the Iowa Supreme Court in the case of Bloomfield Coal & Mining Co. vs. Tedrick, 68 Northwestern Reporter 570, that on sinking a shaft and ascertaining that, contrary to the supposition of both parties, there was no coal under the land, the lessee was not entitled to recover the payments made. The court rested its decision, however, on a finding that the payments were made to avoid forfeiture of the lease pending the lessee's failure to commence operations, and were not intended as an advance payment of royalties, intimating that the lessee would otherwise have been entitled to repayment.

Lessees in a Pennsylvania case, who claimed exemption from liability for a minimum royalty under an express provision of their leases applicable to beds of less than 2½ ft. in general thickness, were held by the Supreme Court of that state to have had the burden of showing that the coal was of less thickness, it not being incumbent upon the lessors to show that the bed in question had a general thickness greater than 2½ ft. This decision was influenced, however, by the fact that it was conceded that there was merchantable and workable coal in the land. The evidence in the case being conflicting on the question as to the actual thickness of the bed, and there being proof tending to show that the lessees had not made proper examinations to test the actual thickness, the lessors were awarded the minimum royalty. (Holt vs. Kelley, 73 Atlantic Reporter 947.)

In the case of Consolidated Coal Co. of St. Louis vs. Peers, 37 Northeastern Reporter 937, the Illinois Supreme Court, in awarding recovery of a minimum royalty, which was guaranteed regardless of whether mining operations should be conducted, decided that the leasing landowner was not required to prove that there was a seam of workable coal under the land, the lease containing no express warranty on that point.

Unexpected inferiority of coal, making it unsalable, was a "circumstance" beyond the lessee's control within the meaning of a lease which required him to pay royalties on not less than 500,000 bu. of coal, unless prevented from taking and shipping that quantity by some accident or circumstance beyond his control, according to the decision of the Kentucky Court of Appeals in the case of Givens' Executors vs. Providence Coal Co., 60 Southwestern Reporter 304.

Effect of Exhaustion of Coal

Exhaustion of coal in the leased land discharges the lessee from further liability under a clause binding him to mine and ship sufficient quantities of coal to produce $5000 in royalties, unless prevented from doing so by unavoidable accident, or occurrences beyond his control. (Pennsylvania Supreme Court, Bannan vs. Graeff, 40 Atlantic Reporter 805.)

On the other hand, in a recent case where a lease provided for a stated royalty and for a minimum production and a minimum rental on that basis, the St. Louis Court of Appeals held that the lessee could not escape payment of the minimum rental on the ground that the coal had been exhausted, so long as he retained possession of the premises under the lease. (Lennox vs. Vandalia Coal Co., 66 Missouri Appeals Reports 560.) And in an early case, McDowell vs. Hendrix, 67 Indiana Supreme Court Reports 513, a lease providing a minimum payment unless no coal should be found and the lease should be abandoned was held not to release the lessee from liability for such rent so long as he retained possession of the land.

A Pennsylvania lessee, who guaranteed a minimum annual royalty for ten years, was declared liable for the full amount, although the coal seam became unworkable in eight years. (Timlin vs. Brown, 28 Atlantic Reporter 236.)

*Attorney at law, St. Paul, Minn.

Discussion By Readers

High Safety Records

As a subscriber and reader of your valued publication, I have read with considerable interest the article in the issue, Feb. 21, in regard to high safety records, and am pleased to see the interest taken in drawing attention to the decided decrease in fatalities, as compared with production. Whether or not this statement from us will be of any special interest, I wish to give it to you anyway.

We have been mining coal in Muhlenberg County, now, for a little better than ten years, and in that time have produced five million tons of coal with a total fatality of six. Last year our output, at the two mines, Luzerne and Graham, was 661,118 tons, without a single fatality.

I think on the whole the fatality per ton is decreasing, in Kentucky; and the mine operators, as well as the employees are showing much interest in making all possible provision for safety.

C. W. TAYLOR, Vice-Pres. and Mgr.,
W. G. Duncan Coal Co.

Greenville, Ky.

List of Coal-Mine Explosions

In looking over a recent issue of COAL AGE, Jan. 10, my attention was attracted to the footnote at the bottom of p. 47, which stated that neither of the two explosions mentioned in the report of Thomas A. Shaw, State Mine Inspector of Arkansas, is found in the list of fatal mine accidents compiled by the Federal Bureau of Mines (Technical Paper 48, Bureau of Mines, Washington, D. C., pp. 67-71, inclusive).

The completeness of the Bureau's list is appreciated by all, and especially by anyone who has attempted a like compilation. The difficulty in locating and securing correct information on the mine catastrophes of even as recent a date as 1905 can be better estimated when it is said that in some instances explosions wherein as high as fifty lives were lost, were then given much less attention and publicity in the technical mining papers, than now. The incompleteness of state mining reports of a decade ago is well known and these often offer but little help to such investigations. In order that the explosions record, however, may be made still more complete, I beg to submit four such occurrences that are not found in the Bureau's list. They are as follows: Flat Top mine, Littleton, Ala., Dec. 1, 1903, 4 lives lost; Short Creek mine, Short Creek, Ala., Oct. 29, 1908, 6 lives lost; Jumbo mine, Antler, Okla., Nov. 28, 1910, 13 lives lost; Gayton mine, Henrico, Va., January, 1909, 6 lives lost.

E. N. ZERN,
Professor Mining Engineering,
West Virginia University.

Morgantown, W. Va.

[We would draw attention to the fact that the list of mine explosions and other mine accidents, published by the Federal Bureau of Mines and referred to above, is limited to a fatality of five lives lost as a result of the accident. Our correspondent mentions one explosion, that in the Flat Top mine, Littleton, Ala., Dec. 1, 1903, in which only "four lives were lost." This explosion would not properly be included in the Bureau's list.

In the hopes of completing, as far as possible, the list of mine explosions that have occurred in the United States and Canada up to the present time, we are making editorial mention of the matter, and hope to receive, from our readers and all classes of mining men, any information that will aid in completing the tabulated list. See p. 416.—ED.]

The Mine-Run Problem

Letter No. 3—Referring to the article of S. F. Rock, COAL AGE, Feb. 14, p. 296, it seems to me that the method he suggests for solving this problem is not practical, since the proportions of lump coal and screenings vary to such an extent, in different districts and even in different parts of the same mine, that if there were to be established an agreed price for lump coal and another for nut, pea and slack, the result would prove of advantage to some and a decided disadvantage to others. Such a method would, therefore, be no improvement over the present system of paying miners on the basis of screened lump coal. One of the chief objects of the miners, in demanding the mine-run system of payment, is that justice might be secured by *all*.

At the present time, I recall a mine where the coal on the north side was mined in large lumps without shooting, while the percentage of nut and slack would not run above 15 per cent. The conditions of mining in the rest of the workings were about normal, except in two rooms that were narrowed and were being driven to the crop, to provide good natural drainage for the mine. The coal mined in these two rooms was estimated to contain about 50 per cent. of nut and slack, which all passed through the screens and for which the miner received no pay. The average percentage of screenings for the entire mine was about 22.5 per cent., which is somewhat below the average percentage for that district. This is not an imaginary case, but the facts as stated are the result of my observation while employed at the Copperhead mine, near Gore, Ohio, operated by the Hocking Fuel Co., of Columbus.

Mr. Rock suggests that the rate of payment be based on the proportion and price of the two grades of coal produced, lump and screenings. For example, assuming that the average selling prices are $1.65 for lump, and say 50c. for screenings, per ton, if the price for mining lump is 87½c., the mining price for screenings would be obtained by the following proportion:

$$1.65 : 0.50 : : 0.875 : x = 0.265$$

For the sake of illustration, let us apply this rule and assume a miner mines, say 10 tons of coal on the north side of the mine mentioned above; and compare this with 10 tons mined by a miner, in driving one of the places

running to the crop, as mentioned. The earnings of these two men, in mining 10 tons of coal, would then be as follows:

North side of mine, producing 85 per cent. lump and 15 per cent. screenings,

8.5 tons	@ $0.875	= $7.44
1.5 tons	@ $0.265	= $0.40
Total		$7.84

Crop workings, producing 50 per cent. lump and 50 per cent. screenings,

5 tons lump	@ $0.875	= $4.37
5 tons lump	@ $0.265	= $1.33
Total		$5.70

This shows a difference of $7.84 — $5.70 = $2.14 in the earnings of these two men, in mining 10 tons of coal in their several places. While I willingly admit this situation to be anomalous, I believe Mr. Rock would be confronted with difficulties from the start, in attempting to apply his proposed method of payment, practically.

Careful study of the situation seems to indicate that the only proper solution to this question is a flat, mine-run basis of payment. In opposition to this plan, Mr. Rock states that miners will practice "hard shooting," with the result that a larger percentage of fine coal would be produced, and more impurities will be left in the coal. In the study of the question, the Ohio Mining Commission recognized this fact, which is quite generally conceded by all. I believe that experience will teach miners the folly of such practice, which, undoubtedly, would soon result in the adoption of a rule restricting the weight of charge to be employed in shooting coal.

In the meantime, Ohio operators, confronted as they are at present with the necessity of changing their equipment from screens to chutes, and being forced to compete with natural and economic conditions in West Virginia, face a considerable hardship. The estimated cost of making these changes at the mines of Ohio is $1,000,000.

Notwithstanding these facts, it seems only right that miners should be paid for their coal on a mine-run basis. This should have been done before; but, whatever trade adjustments are necessary should be considered in the sense of correcting an existing wrong. We are proud to say that Ohio is the pioneer in such legislation. In passing through a crisis demanding many reforms, such as Ohio is experiencing at the present time, the needed legislation, if not proved unconstitutional, must later be followed by other states. Such was the case in regard to the Workmen's Compensation act, which is now in force in at least 15 states. Let us hope for the final and equal adjustment of these matters that will reduce the hardships for the operator and provide greater justice for the miner.

GEORGE N. LANTZ.

New Straitsville, Ohio.

Longwall Mining Methods

Letter No. 6—My attention was especially attracted by Letter No. 3, in answer to the inquiry on longwall mining. Both Letters Nos. 3 and 4 refer to the longwall-advancing system, instead of the retreating system asked in the inquiry.

Mr. Marson, in Letter No. 3, states that one gateway is provided for each 100 ft. of face, the gateway to be 9 ft. wide, with 6-ft. packs on each side. He uses, also, three rows of posts along the face. In my experience, these gateways are too far apart for safety, for the amount of support shown between them. The 6-ft. gate-side packs are too narrow, and would be thrown into the gateway when the weight comes on them. I consider that gateways 7 ft. wide, with 3-yd. packs; crossroads, 10 ft. wide, with 4-yd. packs; and main roads, 12 ft. wide, with 4-yd. packs on each side, are necessary for safe working, under the conditions given. In such an advancing system, the small gateways should be cut off by the crossroads, at a suitable distance, and new ones started.

As I understand this inquiry, it refers to the retreating system; which consists in driving haulage roads and airways to the line or boundary, and bringing back the coal by the longwall face. The roads being driven in the solid coal, as the face retreats toward the shaft, the roof is allowed to fall completely. In this system, no roads are maintained in the goaf.

In respect to the style of timbering such a longwall face, I would refer Bituminous to Letter No. 1, p. 99, COAL AGE, Jan. 10. All timber is withdrawn as the face recedes. The work is much more simple than when the roads must be maintained in the goaf, as in the longwall-advancing method. I much prefer having the roadways leading to the face 54 ft. apart, as there is less danger to the loaders, and the face can be cleaned up quicker. Wooden rails should be used at the face, and the size of the car should be such that they can be readily handled along the working face.

LONGWALL.

Marianna, Penn.

The Certificate Law

Letter No. 22—I have noted with interest the letter of Wm. Kellum, No. 15, COAL AGE, Jan. 31, p. 217, on The Certificate Law. I fully agree with Mr. Kellum in his statements, especially where he says that a man may possess a first-class certificate and yet be deficient in many points that are essential to the making of an efficient and competent mine foreman.

I have worked in the mines 26 years, and during that time have filled every position from a trapper to assistant mine foreman. For the past 10 years I have been employed in the capacity of fireboss. Having but a fair education myself, I feel the need and realize the importance of every miner making an effort to secure as much education as possible. In my mining experience I have met many men who could not read or even write their own name, but who are first-class mining men, from a practical standpoint, and men whose judgment in practical mining matters can be safely trusted. They are men whom I and many others would not be afraid to follow in any mine where gas is generated.

It is my belief that a man should have this practical experience before he can be trusted with a safety lamp to examine workings for gas where so many lives are at stake. I have known firebosses who hold certificates, but who did not seem to know the importance of cleaning their lamps, but who would go into the mine and proceed to examine for gas with a safety lamp that was so clogged with coal dust and oil that you could not see through the gauze.

In many cases, these men would carry a flame as large as that of an ordinary mine lamp, when making a test for gas. It is needless to say that such men should neither hold a certificate nor be allowed to carry a safety lamp, much less to examine the mine for gas.

I would say, therefore, in conclusion, that practical experience should be considered an essential qualification for every man holding a certificate. No examining board should grant a certificate of competency to a man who has had no practical experience and does not know what is necessary in the handling of a safety lamp.

FIREBOSS.

Huntington, Ark.

Letter No. 23—The recent letters discussing the question of the certificate law have interested me very much. In my opinion, anyone who attempts to handle men and conduct mining operations underground should be a properly certified person. I do not see the need, however, of a law compelling a man to take more than one examination, in the state where he is employed. I do not believe in the interchange of certificates issued in different states.

In regard to residents of another state obtaining certificates of competency in a state other than their own, I believe the state mining law should protect its own citizens. If a man desires to obtain a certificate in another state, let him become a citizen of that state, so that he can study and become familiar with the state mining laws and the conditions in the mines. I consider our Illinois law is right in this respect, in not permitting a man to take an examination, except he is a resident of the state.

In discussing this question, we should remember that the certificate law does not make good mining men. Practical experience is necessary when operating a mine underground, and I would rather trust a really practical man with the responsibilities that rest on the mine foreman than a man who has obtained his mining knowledge from books only. I believe every mine manager (foreman) should keep uptodate by reading mining journals, as we can learn much from the experience of others.

Speaking of examination for certificates of competency, there are many mine managers (foremen) in this field who could not secure a rating in an examination, at the present time; nevertheless, these men are successful in the operation of their mines and are competent to have charge of mines.

COUNTY MINE INSPECTOR.

Catlin, Ill.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

THE DECIMAL SYSTEM

The common system of notation, as previously explained, multiplies the value of a figure **ten** times for each successive place, from the units place to the left. Thus, beginning at units place in a line of figures and counting to the left, the order of notation is units, tens, hundreds, etc., each successive position to the left increasing the value of the figure ten times or multiplying its previous value by ten.

Advantage has been taken of this principle to extend the same notation to the right of the units place. By the same law of notation, beginning at units place and counting to the right, the value of a figure is now divided by **ten,** for each successive place to the right, making the order of notation to the right thus, units, tenths, hundredths, thousandths, ten thousandths, hundred thousandths, etc.

The Decimal Point—The extended decimal system is thus seen to include a notation of units to the left and of fraction units to the right. To divide these two branches of the system a point called the "decimal point" is used. The decimal point is placed immediately to the right of the units place, thus dividing the fractional units on the right from the units on the left.

DECIMAL FRACTIONS

A fraction is a part of a whole. A numerical fraction is a part of a unit or one; its value is therefore always less than one.

There are two general classes of fractions; namely, "common fractions," which have been already described and "decimal fractions."

A **common fraction** is one whose fractional unit is not a decimal part of a unit; or, in other words, is not obtained by dividing one by ten or a multiple of ten; as ½, ⅓, ¼, etc.

A **decimal fraction** is one whose fractional unit is obtained by dividing one by ten or any multiple of ten; as $^1/_{10}$, $^1/_{100}$, $^1/_{1000}$, etc.

Writing Decimal Fractions Decimally—As explained above, in the decimal notation, the first place to the right of the decimal point expresses tenths; the second place, hundredths, etc. Hence, the fractional unit $^1/_{10}$, written as a decimal, is 0.1; the fractional unit $^1/_{100}$ is 0.01; and in like manner $^1/_{1000} = 0.001$; $^1/_{10000} = 0.0001$; etc.

It follows, also, that any decimal fraction, $^7/_{10}$, $^{62}/_{100}$, $^{79}/_{1000}$, etc., may be written decimally thus, 0.7, 0.62, 0.079, etc.; always observing to write the numerator of the fraction, with as many decimal places (places to the right of the decimal point) as there are ciphers in the denominator, if necessary writing as many ciphers immediately after the decimal point as are needed to make the required number of decimal places. To illustrate, the following examples are given:

$$\frac{37,062}{100,000} = 0.37062 \qquad \frac{50,120}{1,000,000} = 0.05012$$

$$\frac{207}{100,000} = 0.00207 \qquad \frac{500}{1,000,000} = 0.0005$$

The Coal Age Pocket Book

It is important to note that when the numerator of a decimal fraction contains fewer figures than there are ciphers in the denominator, it is necessary, in order to write this fraction as a decimal, to prefix ciphers to the numerator so that the number of decimal places expressed will equal the number of ciphers in the denominator. For example $^5/_{100} = 0.05$.

It is evident that any ciphers standing on the right of a decimal can be dropped without changing the value of the decimal. Thus, $0.500 = 0.5$; $0.0230 = 0.023$.

Again, the numerator of a decimal fraction may contain more figures than there are ciphers in the denominator, as in an "improper fraction" previously defined. In that case, all that is necessary to express this fraction as a decimal is to write the numerator as a number and point off from the right, by a decimal point, as many decimal figures as there are ciphers in the denominator of the fraction. For example, the following improper decimal fractions expressed as decimals are

$$\frac{389}{100} = 3.89; \qquad \frac{65}{10} = 6.5; \qquad \frac{4500}{100} = 45.00 = 45$$

Rule—To express a decimal fraction as a decimal, first cancel any ciphers at the right of the numerator and as many in the denominator of the fraction. Then write the remaining numerator as a number and point off from the right as many decimal places as there are ciphers remaining in the denominator, if necessary prefixing ciphers to the number until the required number of decimal places are obtained. The result is the desired decimal value of the fraction.

To Express a Decimal as a Fraction—The operation is the reverse of that just explained and is as follows:

Rule—To express a decimal as a fraction, write the given decimal as a number, omitting the decimal point and any ciphers immediately following the point and preceding this number. Taking this for the numerator of the required fraction, write beneath it for the denominator one with as many ciphers annexed as there were decimal places in the original decimal. Finally reduce this fraction to its lowest terms.

The above rules, each, apply alike when an improper decimal fraction is to be reduced to a whole number and a decimal; or, vice versa, when a whole number and a decimal is to be reduced to fractional form. In the latter case, simply drop the decimal point and write the result over one with as many ciphers annexed as there were decimal places in the number.

To Express a Common Fraction Decimally—Whether the given fraction is a proper or an improper fraction the operation is the same and is as follows:

Rule—Proceed to divide the numerator by the denominator, as in the process of division; only write as many decimal ciphers on the right of the dividend as desired and separated from it by a decimal point. Proceed as in the division of decimals. The quotient obtained will be the required decimal value.

Inquiries of General Interest

Study Question--Hoisting Problem

We have been studying the answer to the third question, COAL AGE, Vol. 4, p. 357. The question reads as follows:

What kind and size of hoisting engine would you install to hoist 1200 tons of coal from a shaft 400 ft. deep, in eight hours, with a steam pressure of 70 lb. gage? The weight of coal in each car is 3000 lb. Allow 20 per cent. for resistance of engine, ropes and pulleys; also make allowance for the time lost in caging.

The answer to this question states that the size of duplex direct-connected engine required is 16x18 in., the engine running at a speed of 200 r.p.m. It is found that the maximum speed of hoisting, in this case, is 20 ft. per sec., or $60 \times 20 = 1200$ ft. per min.

In order to give this speed of hoisting when the engine is running at 200 r.p.m., the circumference of the winding drum would have to be $1200 \div 200 = 6$ ft., and the diameter $6 \div 3.1416$, which is less than 2 ft. But, the hoisting rope being 1 in. in diameter, would it not be better to design this engine with a longer stroke and running at a lesser speed, so as to provide a drum having a larger diameter?

* * *

In the same connection, in studying the answers given to a number of questions asked at different state examinations, I notice that it is sometimes stated that, in a two-cylinder engine with the cranks set at right angles, so that while one cylinder is exerting its full force the other is on dead center and doing no work, the power of such an engine is measured by one of its cylinders only.

I fail to understand how the combined power of two cylinders, the cranks being set at right angles, can only equal the power of a single cylinder. I readily understand that it is necessary to have each cylinder strong enough to start the load off the bottom, under any and all conditions, assuming, for instance, that one crank is on dead center. But, it does not appear to me strictly correct to say, "The horsepower of such an engine is measured by one of its cylinders only." If I am in error, please put me right.

S. A. DRIVER,
Mining Engineer.

Warrior, Ala.

We are glad to have our correspondent draw attention to the oversight in the answer to the question quoted above. The difficulty, however, is not in the speed of the engine, since, in order to obtain the highest efficiency of a common, slide-valve engine, it should be designed on a piston speed varying from 600 to 800 ft. per min. The speed of the engine, as calculated in the answer to this question, namely 200 r.p.m., is, therefore, correct.

The oversight, in answering the question, consists in the fact that a geared, or second-motion engine, should have been used. In hoisting practice, the engine is under better control in hoisting from deep shafts, at a fairly high rate of speed, when a second-motion engine is employed. This gives a lesser speed of the winding drum, while the speed of the engine is sufficient to yield a good efficiency.

It is true that regard must always be had to the relation between the diameter of the rope and that of the drum. In the use of steel ropes, the diameter of the winding drum should not be less than sixty times that of the rope, in order that the bending stress in the rope when wound on the drum shall not be excessive. In special cases, it is necessary to calculate the bending stress in the rope, for the size of drum employed, in order to ascertain that the rope is not strained beyond the safe elastic limit of the steel. Ordinary practice, however, assumes that it is safe to make the diameter of the drum or sheave, sixty times that of a steel rope, having six strands and 19 wires in each strand.

Using, in this case, a 1-in. cast-steel, 6-strand, 19-wire rope, the required diameter of the winding drum is $60 \times 1 = 60$ in., or 5 ft.; and its circumference, $5 \times 3.1416 = 15.7$ ft. The required speed of the drum, for a hoist or rope speed of 1200 ft. per min., is then $1200 \div 15.7 =$ say 76 r.p.m. The engine running at 200 r.p.m., the required ratio of gearing is 200 : 76 = say 8 : 3. That is, for every three teeth in the pinion, there should be eight teeth in the drum gear. It would be even better to use, in this case, a 6-ft. drum and a ratio of gearing of say 25 : 8; that is, for every eight teeth in the pinion gear, there would then be 25 teeth in the drum gear. In more exact calculation, in practice, allowance must also be made for the diameter of the rope increasing the effective diameter of the drum When, for example, a rope 1 in. in diameter is wound on a drum, 6 ft. or 72 in. in diameter, the effective diameter, sometimes called the "diameter of winding" is equal to the diameter of the drum plus the diameter of the rope.

In answer to correspondent's second question, it must be remembered, as he has stated, the lifting power of a single cylinder of a hoisting engine must be such as to pick up the load from the bottom, without difficulty and when the other engine is on dead center. This lifting power is quite separate from the actual horsepower of the engine. In most cases, when the horsepower of an engine is calculated for a single cylinder only, the lifting power of that cylinder under full steam pressure will be sufficient to pick up the load readily when the other engine is on dead center. This is owing to the initial cylinder pressure being greater than the mean effective pressure due to expansion of the steam after cutoff.

It is incorrect, however, to state that the horsepower of a duplex engine is measured by one of its cylinders only. The power of a duplex engine is always double the power of a single engine of the same size and running at the same piston speed. However, in hoisting practice, it is essential to have a surplus power and, for this reason, the required size of a hoisting engine is generally estimated on the power of a single cylinder, which gives a sufficient lifting power, as just stated.

Examination Questions

Mine Managers' Examination, Held at Springfield, Ill, Feb. 9, 1914

(*Selected Questions*)

Ques.—A mine is ventilated by three splits of air, *A*, *B* and *C*, which take, respectively, 2500, 1500 and 2000 cu.ft. per min., making a total of 6000 cu.ft. of air in circulation. What will each split take if the total circulation be increased to 75,000 cu.ft. per min.?

Ans.—Assuming that this increase, in the total circulation in the mine, is caused wholly by an increase in the ventilating power or the power on the air, the quantity of air passing in each split will be increased in the same ratio, namely, 6000:75,000; or 1:12.5. The circulation of air in each split is, therefore, as follows:

Split A, $2500 \times 12.5 = 31{,}250$ cu.ft. per min.
Split B, $1500 \times 12.5 = 18{,}750$ cu.ft. per min.
Split C, $2000 \times 12.5 = 25{,}000$ cu.ft. per min.

Total, 75,000 cu.ft. per min.

Ques.—A barometer registers 30 in. at the surface; what will it register at a point 1890 ft. below the surface?

Ans.—Ignoring any increase or decrease of ventilating pressure in the mine, caused by the action of a blower or exhaust fan, the increase of barometric pressure, due to the depth of the shaft, may be taken as, approximately, 1 in. of mercury for every 920 ft. of air column; which gives, in this case, $1890 \div 920 =$ say 2 in., making the barometric reading, at the foot of the shaft, in this case, $30 + 2 = 32$ in.

Ques.—Name three gases found in coal mines and that are dangerous. What are their chemical symbols and comparative weights?

Ans.—The three dangerous mine gases, commonly found, and their respective molecular weights are: Methane or marsh gas (CH_4), molecular weight, 16; carbon monoxide (CO), molecular weight, 28; carbon dioxide (CO_2), molecular weight, 44.

Ques.—If 10,000 cu.ft. of air are passing per min., through an airway 8x10 ft., under a pressure of 13 lb. per sq.in., what is the estimated length of the airway?

Ans.—First, write the formula for the unit of ventilating pressure, in terms of the quantity of air in circulation,

$$p = \frac{klOq^2}{a^3}$$

The perimeter of an 8x10-ft. airway is $2\ (8 + 10) = 36$ ft.; the area, $8 \times 10 = 80$ sq.ft. Substituting these and the given values in the above formula gives,

$$13 = \frac{0.00000002\ l \times 36 \times 10{,}000^2}{80^3} = \frac{9\ l}{64{,}000}$$

and

$$l = \frac{64{,}000 \times 13}{9} = 92{,}444+\ ft.$$

Ques.—If a mine-ventilating fan, running at 80 r.p.m., gives a water gage of 3.75 in., at what speed will this fan give a water gage of 1.82 in.?

Ans.—Assuming the conditions in the mine remain unchanged, and ignoring the slight change in the efficiency of the ventilator, the speed of the fan is ordinarily assumed to be proportional to the quantity of air circulated, on which basis the speed of the fan would vary as the square root of the ventilating pressure. In other words, the speed ratio is equal to the square root of the pressure or water-gage ratio. This assumption gives, calling the required speed of the fan x,

$$\frac{x}{80} = \sqrt{\frac{1.82}{3.75}} = \sqrt{0.4853} = say\ 0.7$$

$$x = 80 \times 0.7 = 56\ r.p.m.$$

In actual practice, however, the fourth power of the speed of the fan is found to vary, approximately, as the fifth power of the quantity, which makes the speed ratio equal to the eighth root of the fifth power of the water-gage ratio. This calculation can only be made satisfactorily by the use of logarithms, and gives for the required speed of the fan, in this case, say 51 instead of 56 r.p.m.

Ques.—If the ventilation of a mine was insufficient, and you could not increase the power, how would you increase the circulation of air in the mine?

Ans.—Proceed to clean up the airways by loading out all falls of roof and other rubbish; enlarge all breakthroughs, straighten the air courses and shorten, as far as practicable, the distance the air must travel. Split the air current wherever it is possible to do this without reducing the velocity of the current below that required for good ventilation and the removal of the gases that accumulate in the workings. Remove every unnecessary obstruction in the air courses and avoid sharp angles in all airways, or obstructing the roads and air courses by standing loaded cars in them.

Ques.—How much more resistance will a current having a velocity of 600 ft. per min. meet, than one with a velocity of 500 ft. per min., the dimensions of the airway being the same in each case?

Ans.—For the same dimensions of airway, the resistance varies as the square of the velocity of the current; or the ratio of increase is equal to the square of the velocity ratio, which is, here $600^2 : 500^2 = 6^2 : 5^2 = 36 : 25$. This shows an increase of $\frac{(36 - 25) \times 100}{25} = 44$ per cent.

Ques.—The pipe line in a slope is 144 sq.in. in area and 2000 ft. long; the slope dips 1 in 10. What is the presure per square inch, and the total pressure on the pipe, at the bottom of the slope?

Ans.—The vertical head, for this length of pipe, is $2000 \div 10 = 200$ ft. The pressure per square inch, due to this head of water, is $200 \times 0.434 = 86.8$ lb. per sq.in. The total pressure, for the entire sectional area of the pipe is, then, $144 \times 86.8 = 12{,}499.2$, say 12,500 lb., or 6¼ tons.

Coal and Coke News

Harrisburg, Penn.

A report covering the cost per mile of hauling anthracite coal from the mines to Philadelphia as compiled by Price, Waterhouse & Co., accountants is now in the hands of the Public Service Commission. The Commission will hear arguments on the question of freight rates at the capitol on Mar. 24, and meanwhile it is refusing to discuss findings.

From an authentic source it was learned that the accountants had not only reported the cost per ton per mile, but that the figures of the report were so low that the railroads would vigorously combat them. It was said that the figures were less than the cost estimated by experts who testified before the old State Railroad Commission. Furthermore, it was said, the accountants' figures would compare favorably with those introduced by the Interstate Commerce Commission in regard to the Central R.R. of New Jersey at a recent hearing in Philadelphia. The Interstate Commerce Commission found that the average cost to the New Jersey Central reduced to the per ton mile basis would be 3.3 mills.

The employment of the New York accountants by the Commission really grew out of a statement made by Wharton Baker, a veteran financer, who declared the railroads could ascertain the cost per ton per mile if they wanted to. The railroad men, at the Commission hearings, had ridiculed the idea and said it could not be done. Mr. Baker made an affidavit that he had seen such statistics in possession of the Philadelphia & Reading Ry. Co. Then the Commission agreed to put the accountants at work.

Rates now charged by the railroads on hauls, from the Lehigh region to Philadelphia are $1.86; to Germantown, $1.96; to Chestnut Hill, $2.06. Experts had complained that it should not exceed 62 cents. The Interstate Commerce Commission figures showed that it cost 59 cents a ton from the Wyoming region to tidewater at New York, or 3.3 mills per ton per mile. On this basis the cost of hauling a ton of coal from the same district to Philadelphia would be 51.38 cents and the cost of assembling was shown to be 5.2 cents. The total rate charged by the railroads is $2.10.

AGITATION FOR ORGANIZATION

The agitation for organization which is now going on in the anthracite region by that class of unorganized labor; namely, assistant mine foremen and fire bosses is worthy of more than passing thought.

That there will be opposition not only from the coal companies, but from others in the ranks whose interests seem to be identical with those of the companies, toward the organization of the fire bosses into a branch of the United Mine Workers, is becoming evident every day.

It is asserted by some coal operators that with the foremen allied with the union, the law of the latter will prevail, and that the foremen cannot be considered servants of the companies to carry out all orders issued.

At the meeting of the tri-district board of the United Mine Workers of America, held at Wilkes-Barre on Feb. 28, no definite action was taken to admit these men to the union, either as a separate organization or as individuals. In fact the by-laws and the constitution of the organization practically stipulates that these men shall not be admitted to membership.

Charges were also preferred at this board meeting that certificates to foremen and assistant foremen have been issued to men not qualified for the positions. The miners for some time have been complaining about the powder furnished them, and have appointed a committee to take this question up with James E. Roderick, chief of the Department of Mines and Dr. Holmes of the Federal Bureau of Mines, and there is a possibility of compelling the companies to stamp powder kegs with the grade and percentage contained. It was charged by men from the lower fields that some of the companies had refused to stamp the kegs.

PENNSYLVANIA

Anthracite

Drifton—The Lehigh Valley Coal Co.'s stripping work in the vicinity of Freeland and Drifton has been suspended until spring, due to the cold weather.

Forest City—The report of Benjamin Maxey, state mine inspector of the 21st district, which comprises Sullivan, Wayne, Susquehanna Counties, and a portion of Lackawanna County, shows 22 men were killed during 1913. Eleven wives were made widows and 31 children were left orphans as a result of these accidents. The tonnage for the year was 3,145,662 thus making one fatal accident for every 142,994 tons of coal mined.

Mahanoy Plane, Penn.—The contract for the erection of the Lawrence breaker has been awarded to Wheeler-Reilly Construction Co. The structure when completed will be one of the largest in the anthracite coal region and is being erected by the Maderia-Hill Coal Co.

Lattimer—The Pardee interests around Harwood, have passed into the hands of the Lehigh Coal & Navigation Co., and it is stated that the mines will no longer be operated for marketing purposes. The remaining coal will be used at the Harwood power plant.

Edwardsville—No further trouble is expected from the fire which broke out in No. 3 shaft of the Woodward Colliery which broke out about Feb. 24. The officials of the Lackawanna Co. report that the fire has been sealed up with a firewall in the Hillman vein and this wall will not be removed until the fire is extinguished.

Wilkes-Barre—A miner and his laborer in the Pettebone Colliery of the D. L. & W. R.R. Co. of Dorrancetown recently had a narrow and fortunate escape from death. After completing their day's work they found themselves imprisoned by a mine fire. Fearing an explosion of gas they retreated far into the slope, where lying flat on their faces they remained for about an hour and a half while a rescue corps fought the fire.

Bituminous

Philadelphia—Unable to reach an agreement upon the wage scale, the joint conference of operators and miners from Western Pennsylvania, Ohio, Indiana and Illinois adjourned on Feb. 26. It is announced that this action does not necessarily mean a strike, as the two sides may get together in another effort to reach an agreement.

Greensburg—According to the report of Chauncey B. Ross, Inspector of the 2nd Bituminous District, embracing much of Westmoreland County, the Jamison Coal & Coke Co. is the largest producer of coal and coke in the district. This firm produced coal to the amount of 9,037,469 tons in 1913, and manufactured coke to the amount of 2,716,148 tons. In the district were 57 mines, 56 of which were in operation There were 33 fatal accidents underground and four outside.

Somerset—According to the report of inspector Fletcher W. Cunningham, the death toll in the coal mining industry in the 20th Bituminous District including the greater part of Somerset County during 1913 was one human life for every 265,738 tons of coal produced. The total production of the county, part of which lies in the 24th Bituminous District was 9,172,389 tons.

Waynesburg—Figures compiled in the offices of the County Commissioners of Greene county show that there are undeveloped in 17 of the 18 townships of the county 340,000 acres of coal. Of this amount 274, 699 acres are in the hands of investors and 65,301 in the hands of farmers.

Lilly—A single stockholder has petitioned for a receiver for the Lilly Coal Co. There is no financial disability, but internal dissatisfaction.

WEST VIRGINIA

Fayetteville—After all the evidence had been submitted to a jury in the case of John M. Henson vs. the Quinnimont Coal Co. attorneys for the defendant asked the court to direct a verdict in favor of the plaintiff in order that the case might be appealed to the Supreme Court. Henson was a check weighman. Certain of the miners protested to the company against having his pay taken from them, and the company therefore refused to pay him on their checks. Henson brought suit to recover and the case will now go to the Supreme Court in order to have the law settled.

Charleston—It is expected that a permanent organization of the operators along the line of the Chesepeake & Ohio

Ry. will be perfected at a meeting to be held on Mar. 7. This organization will then be sufficiently strong in numbers and financially to secure at least the shipping rights of each member. The principal idea is to prevent the delays in shipment arising upon various roads connecting the Chesapeake & Ohio with the Great Lakes.

A delegation representing the Kanawha Coal Operators Association called on the Public Service Commission recently for the purpose of hearing interpretations on parts of the Workmen's Compensation Law. The operators submitted a list of questions covering conditions such as are most frequently met with in the occurrence of accidents in and about the mines. Answers to these were given verbally and in writing. The operators now declare that they have a more lucid understanding of the working of the new legislative act.

TENNESSEE

Nashville—The recent order of the Interstate Commerce Commission requiring reciprocal switching of coal in Nashville yards between several roads has resulted in a considerable stimulation of activity in the handling of rail coal, as it means a saving of 10 to 20 cents a ton. Applications have been made by the railroad involved for an injunction, however, and it is possible that the old rates and charges will be again placed in effect, pending prolonged litigation.

KENTUCKY

Burlington—Options recently taken by the Deep Water Coal Co. on properties in Hopkins County will be closed soon. Steps are progressing as rapidly as the nature of the work will permit for abstracts to be drawn of certain working properties and also some undeveloped fields of mining rights. The taking over of the operating properties and the development of the new ones, will mean much to Hopkins County.

Pikeville—Six modern and well-equipped coal operations are now working on full time on Marrowbone Creek. The Allegheny Coke Co., which succeeded the Mitchell Coal Co., operates 150 ovens, which convert its entire output into coke, which is marketed and consumed within a radius of 200 miles of the mines. Nine thousand tons of coke were shipped during last year after June 1, with only a part of the ovens completed. The company contemplates doubling its capacity this year, using 300 ovens, and getting out a correspondingly increased amount of coal.

Henderson—Several coal mines in this vicinity have been flooded recently, the snow and rain which fell during the past two weeks, followed by thaws, resulting in putting a number of streams out of their banks and raising the Ohio River almost to flood stage.

Frankfort—A bill has been introduced in the Kentucky legislature, and referred to the committee on Mines and Mining, requiring corporations paying employees in scrip to redeem the same in lawful money on demand. It is significant that the bill was referred to the mining committee, although coal companies were not named in it. It is stated, however, that few companies in Kentucky pay in scrip.

OHIO

Coshocton—The mining tools, mules and other personal property of the Daily Cannel Coal Co. were recently sold to satisfy a claim for lumber furnished.

Salem—About 80 men entombed in the Peerless mine, near here, by a cave-in worked from about noon, Feb. 24, until the morning of Feb. 27, when they finally dug their way out. A runway trip heavily loaded, broke down timbers supporting the roof, which caved in, blockading the mine entrance.

INDIANA

Indianapolis—A suit has been filed in the Federal Court here by the J. B. Arpin Coal Co., of Brazil, asking $10,000 damages from the Browning Manufacturing Co. and the Browning Engineering Co. because, as alleged, a steam shovel failed to come up to guarantee, making it necessary for the company to cancel valuable contracts.

The Indiana Supreme Court affirms the judgment of a lower court for $25,000 which Benjamin Simpson obtained against the Big Four railroad. He owned a farm in Clay County under which was coal, the upper vein lying within 40 ft. of the surface, and possessing a good mine roof. In taking an additional strip of land for double tracking the railroad company lowered the track grade 30 ft. The roof of the mine caved in and the mine became flooded and ruined. Simpson began suit for $150,000 damages.

ILLINOIS

Springfield—The Pittsburgh Coal Co. was recently granted a deficiency decree for $2,787,837.50 against the Illinois Collieries Co. This was granted on the evidence that the Pittsburgh Coal Co. owned that amount of the bonds of the bankrupt Collieries Co., as against $195,175 held by all other bond holders. The Collieries Co. was recently disposed of at receiver's sale for $126,000. The property consists of eight mines in central Illinois.

Canton—According to the report of the State Mining Board covering the fiscal year from June 30, 1912, to June 30, 1913, a total of 3672 men were employed in the 129 mines of Fulton County within the period in question. A total of 2,154,799 tons were produced by hand mining and 378,220 tons by machinery. During the period covered, two men were killed and 18 injured in Fulton County mines. Fourteen new mines were opened and 18 mines abandoned, making a net loss of four operating mines.

Taylorville—The mine of the Springfield Coal Mining Co., which was closed when the concern went into the hands of a receiver, was recently reopened with a force of 600 men.

Peoria—The Illinois division of the United Mine Workers of America on Feb. 27 passed a resolution condemning the National Guard and urging that local unions do everything in their power to keep their members from affiliating themselves with that organization. The resolution enumerates that in every industrial struggle the state militia has opposed union labor, and all labor organizations should do all they can against the National Guard in an effort to defeat its purpose.

ARKANSAS

Russellville—The Russellville Anthracite Coal Co.'s mine resumed work recently, after an idleness of several weeks, due to lack of orders. There has been no labor trouble in the Russellville district for two years or more.

OKLAHOMA

Oklahoma City—Evidence in the complaint of the Farmers Fraternal, Economic and Business Association against all coal companies operating in the state, asking for an order directing the latter to sell direct to the consumers, was recently heard by the Corporation Commission. About 40 coal companies were represented in the hearings, and the order governing the case is expected within a few weeks.

Bartlesville—Considerable mystery appears to surround the results of the prospecting for coal on the leases recently taken by A. M. Parsons, west of Copan. Several prospect holes have been put down with a core drill, but the drillers have so far failed to enlighten anyone as to what has been found.

Pahuska—It is believed that northern Oklahoma will be soon enriched by the development of coal deposits that until recently were known only to persons engaged in drilling oil wells. This coal is bituminous of excellent quality, the veins ranging as high as 8 ft. in thickness and lying at a depth of from 70 to 100 ft.

COLORADO

Trinidad—William Diamond, local treasurer of the United Mine Workers, was arrested Feb. 26, charged with aiding deserters from the militia and having government property in his possession. It is alleged that Diamond had uniforms for which he had exchanged citizens' clothes with absconding militia-men. He will be turned over to United States authorities.

FOREIGN NEWS

Paris, France—At a meeting held Mar. 1, of the National Council of Miners' Unions, it was decided to call off the strike of the coal miners begun in the southern coalfield on Feb. 24. The National Council requested the various organizations to have their men resume work Mar. 3.

Brussels, Belgium—Nine coal miners were drowned Mar. 3 in a mine at Bracquegnies, in the Province of Hainaut, by a subterranean stream bursting into the galleries. The danger signal was sounded throughout the mine, and the hundreds of men below hurried to the surface, but nine of those working a long distance from the shaft were caught in the rush of water and were drowned.

PERSONALS

L. P. Miles, of Memphis, Tenn., is reported as contemplating the purchasing and development of 25,000 acres of coal land in the Arkansas field.

Walter L. Keen has been elected vice-president of the Solvay Collieries Co. in place of Dr. L. P. Jones resigned. J. C. Rawn, who resigned the position of general manager of the same company, has been elected consulting engineer.

John C. C. Mayo, one of the best-known coal operators in Kentucky, who has been seriously ill for some time with Bright's disease, is said to be improving at his home at Paintsville, Ky., and his physicians now predict his recovery.

A. P. Devinnish, formerly connected with the W. J. Hamilton Coal Co. will be sales manager of the Hocking Valley Products Co., of Columbus, in the place of T. C. Collins, resigned to take up similar work with the W. J. Hamilton coal company.

B. F. Nigh, secretary of the Michigan-Ohio-Indiana Coal Association has about completed the work of collecting copy for the annual year book of the organization which will be ready for distribution about Apr. 1. It will contain much valuable information relative to the trade in the three states.

Mike Davasconick, one of two coal miners, who were entombed by a cave-in at the Cannon mine of the Pacific Coal Co., at Franklin, Wash., for nearly a week, was finally rescued alive, and, although much weakened from lack of food, the mine physicians say that there is every prospect that he will soon recover his normal strength.

John Nugent was recently given a judgment of $709 against Sam Dixon, and the various companies of which he was general manager, at the conclusion of the case. Nugent, as state labor commissioner, had a contract with the defendants under which he was to induce miners from England, Scotland and Wales, to accept work for the defendants. He claimed that his employers had not settled in full with him for this service.

OBITUARY

Andrew Horatio Reeder, on Feb. 26, died at the Hahnemann Hospital, Philadelphia, Penn., and was buried at Easton, Penn.

Mr. Reeder was born Sept. 9, 1869, at Easton, Penn. He graduated with honors at Lafayette College in the class of 1890 and took a post-graduate course of one year at Lafayette. He was chief engineer for Senators J. G. Davis and Elkins. Later he took charge of the Carnegie coal properties known as the H. C. Frick Coke Co., at Uniontown, Penn. He was also connected with Mr. Fitzpatrick in building and operating the Shamrock plant in the Connellsville region. Later he sold out his interest with Mr. Fitzpatrick and became an expert consulting engineer and in that capacity was employed by the Virginia Iron, Coal & Coke Co. to inspect and make recommendations in connection with its Toms Creek, Va., plant. He became general superintendent and remained in charge of the plant for 18 months. He left Toms Creek to become general manager of the Crows Nest Pass Coal Co. at the request of James J. Hill. He left the employ of the Crows Nest Pass Coal Co. to become general manager of the Stonega Coke & Coal Co., and allied coal, coke and railroad interests at Big Stone Gap, Va. Later he became vice-president and general manager and held this position at the time of his death.

In the year 1895 he married Elsie Longstreet Eckhard, who is a daughter of Dr. Leighton W. Eckhard, of Philadelphia, secretary of the Pennsylvania Bible Society. He is survived by the widow and two children, Andrew H. Reeder, Jr., and Elizabeth Bayard Reeder.

He was a director of the Virginia Coal & Iron Co., Stonega Coke & Coal Co., Virginia Wholesale Co., the First National Bank of Appalachia, Va., and the Interstate R.R. Co.

CONSTRUCTION NEWS

Gatliff, Ky.—The Gatliff Coal Co. is contemplating the installation of an electric-lighting system for its several mining camps. It will furnish current from its own power plant.

Providence, Ky.—The Providence Coal Co. is having several old buildings torn down, and will replace them with a handsome brick structure which will be used for its offices.

Bakertown, Penn.—The Dravo Construction Co., of Pittsburgh, has just been awarded the contract for the construction of two concrete-lined shafts for the Ford Collieries Co., on its property in Allegheny County.

Canonsburg, Penn.—The Pittsburgh Coal Co. is pushing work on the mine which it is preparing to open at a point on the montour R.R., between Hills Station and Thompsonville. The shaft is now down about 150 ft.

Fayetteville, W. Va.—Work will soon start on a new tipple for the New River Co. at Scarbro to take the place of the one recently destroyed by fire. It is probable that this new structure will be built of steel and that it will be enlarged and improved in many ways.

Jackson, Ky.—The Wolf Valley Coal & Lumber Co. is starting a first-class coal operation near Quicksand, 5 miles from here, and will be ready to begin the shipping of coal within two weeks. Over 100 houses are practically complete, and 100 more are to be built.

Big Stone Gap, Va.—The Stonega Coke & Coal Co. has placed with the J. S. Webster Co., of Middleboro, Ky., and Knoxville, Tenn., representing the Webster Mfg. Co., of Tiffin, Ohio, an order for $12,000 worth of conveying machinery, screens and other tipple equipment for its plant at Keokee, Va.

Williamson, W. Va.—The Tug River R.R., a branch of the Norfolk & Western, will be built from Naugatuck across Tug River and into the coal fields of Blackberry Creek, Pike County, Ky., a distance of 18 miles, construction to be started Mar. 1. A number of coal companies will make developments along the new line.

Hazard, Ky.—The Himyar Coal Co. recently organized here, is getting well under way on a coal operation on the Old Combs coal-land tract three miles above here on the Lexington & Eastern R.R. By Apr. 1, the company expects to be shipping from 30 to 40 tons a day. A first-class electrically equipped plant is being installed.

Point Pleasant, W. Va.—Plans for an extension of the Virginian R.R. by a direct route from the Ohio river to Toledo have been prepared by a firm of Columbus, engineers. The proposed route extends from a point near Point Pleasant, W. Va., in almost a direct line to Toledo. The proposed route is 90 miles shorter than that traversed by any other road from the Ohio river to the Great Lakes.

Whitesburg, Ky.—The Mineral Development Co. makes the announcement that it will start immediately the development of a large coal-land tract in the Colly Creek and Kentucky River sections of the coal fields. Several million dollars will be expended in the development. Two industrial cities, it is announced, will be built. J. L. McCormick, Big Stone Gap, Va., will be at the head of the new development.

NEW INCORPORATIONS

Bicknell, Ind.—The Linn Coal Co. has reduced its capital from $30,000 to $10,000.

Altoona, Penn.—The Munster Coal Co. has been organized here with a capital of $6000.

Coal Hill, Ark.—The Peoples Coal Co. has been incorporated here with Martin Rafter, president, and M. W. Rafter, secretary.

Coalton, Ohio—General offices of the Twin Ada Coal Co. have been removed from Jackson to Coalton, Ohio and combined with those of the Harper Coal Company.

Melbourne, Mo.—The Melbourne Coal Mining Co. has been organized with a capital stock of $3000. The incorporators are B. S. Moulton, A. L. Chambers, and Lewis M. Davis.

Austin, Tex.—The Strawn Coal Co. has been organized at Fort Worth with a capital stock of $500,000 which is all paid in. The purpose of this company is the mining, production and marketing of coal and other minerals. The business is to be transacted in Tarrant, Palo Pinto and other counties, while the principal offices will be in Fort Worth. The incorporators are W. Burton, Paul Waples, L. H. McKee, John L. Johnson and A. Deffebach.

Columbus, Ohio—The Seidenfeld-Hammond Coal Co. has been incorporated with a capital stock of $10,000 to en-

gage in the coal brokerage business. The incorporators are Charles Seidenfeld, E. H. Hammond, Louis M. Seidenfeld, Mary Hammond and W. B. Cockrell.

Charleston, W. Va.—The Lincoln Coal Mining Corporation, of Fairmont, has been organized for the purpose of acquiring coal, oil and gas land and developing the same. The authorized capital stock is $150,000, of which $500 has been subscribed and $100 paid. J. H. Ritchie, J. R. Burns, Chas. S. Windsor, W. C. Devault and C. L. Frost, all of Fairmont, are the incorporators.

Viper, Ky.—The Big Bend Coal Co. has been organized here by J. H. Justice, D. T. Rigby, C. H. Barrowman and B. F. Kaylor with a capital stock of $50,000 for the purpose of starting a coal mining development on Maces Creek. The mining plant will be reached by a short line branch of the Lexington & Eastern R.R. It is expected that the development will be started immediately. J. H. Justice will be manager.

Pineville, Ky.—The Asher Coal Mining Co., of Wasioto, has filed articles of incorporation at Frankfort, with a capital stock of $593,000. The incorporators are T. J. Asher, Robert Asher, H. H. Asher, G. M. Asher, M. Brandenburg and A. J. Asher, Jr. The company owns mines at Tejay, Varilla and Colmar, in the Pineville district, which are now operated by the Southern Mining Co., and controls a large acreage in Harlan County.

INDUSTRIAL NEWS

Hopkinsville, Ky.—Henry Wimberg, of Evansville, Ind., has sold the Waverly coal mine to R. C. Arnold, of Cass County, Mich., the price paid, it is understood, being $42,000.

Washington, D. C.—The Pennsylvania Coal Pillar Law of 1891 requiring pillars to be left along the boundary line of adjoining coal properties was recently upheld as constitutional by the Supreme Court.

Indiana, Penn.—The Operators' Coal Co., of Johnstown, has filed deeds of the purchase of, approximately, 5000 acres of land in East and West Wheatfield townships. The price of this property is placed at $240,000.

Pittsburgh, Penn.—The Epping-Carpenter Co. has just completed an extension to its foundry and machine shops, which enables it to properly care for an increasing business. This is remarkable considering the extreme inactivity in the mine-pump business at the present time.

Frank, Alta.—The big coal mine owned by the Canadian Coal Consolidated Co., which went into liquidation some months ago, has been acquired by a French company composed mainly of the bondholders of the old firm. New capital to the amount of $400,000 has been secured and the mine will shortly be re-opened.

Pittsburgh, Penn.—The Concordia Safety Lamp Co. has established offices in the Manufacturers' Building, this city. The specialty of the new firm will be electric safety lamps and accessories, the equipment of electric-lamp cabins and the general lighting of mines. R. Koch is engineer in charge and William Dominick is sales manager.

Pittsburgh, Penn.—A large pumping boat, the property of the Monongahela River Consolidated Coal & Coke Co., was practically destroyed by fire Feb. 27, entailing a loss of $3000. The boat was moored on the south bank of the Monongahela river near the Point Bridge, and, before the fire was extinguished, was burned to the water's edge.

Philadelphia, Penn.—J. B. Kennerly, a coal operator and shipper, with offices in Philadelphia, has filed a voluntary petition in bankruptcy, giving his liabilities as $603,032 and his assets as $6895. He has been engaged in mining and shipping coal from the Beccaria mine at Glasgow, Penn. E. F. Hoffman has been appointed referee in the case.

Huntington, W. Va.—The Banks Supply Co. has been appointed general agent in this district for the Epping-Carpenter Co. This connection is a valuable one for the supply company, owing to the completeness of the line of mine pumps built by the Epping-Carpenter Co. and the possibilities offered for handling this trade in this immediate vicinity.

Franklin, Penn.—To meet the constantly increasing business of the Lake Erie, Franklin & Clarion R.R., the president of the road on Feb. 28, announced that he would place an order for 100 fifty-ton steel coal cars at an early date. Orders for other new equipment have been placed and it is possible that the road will place another order for coal cars in the near future.

Peace River Crossing, Alta.—An important discovery of coal has been made in the Peace River district, Alberta, where there has been a great influx of settlers. An experienced prospector named Edwards, from Colorado, has located a seam of coal about seven miles from Peace River Crossing, which it is anticipated will be of much advantage to the people of the province.

Waynesburg, Penn.—The report is current here that J. V. Thompson, of Uniontown and associates have closed one of the biggest coal deals ever consummated in Green County. It is alleged that they have sold to H. C. Frick 10,000 acres of coal land in Perry Township at $600 per acre. The tract surrounds the town of Mount Morris and is 8 miles from the Monongahela River.

Victoria, B. C.—A motion of lack of confidence in the conservative ministry was introduced by John Place, of Nanaimo, on Feb. 16, in the Legislative Assembly of British Columbia, and the premier, Sir Richard McBride, replied to the criticisms of the mover. The cause for this action, intended to overthrow the ministry, was the alleged mismanagement of the situation arising out of the Vancouver Island strike.

Connellsville, Penn.—According to the mine inspector's report for the year, 1913, a total of 5,282,264 tons of coal were mined in Jefferson county and 9,065,553 tons in Indiana county. This latter tonnage exceeds by nearly 2,000,000 tons, the production of 1912, while that of Jefferson county is one-half million tons greater than in the preceding year. There were 60 fatal accidents in Indiana, Armstrong, Clearfield and Jefferson counties.

San Francisco, Calif.—The sale of Japanese coal to foreign counties is steadily increasing, one interesting feature of the trade being the demand for the better grades of this fuel on the Pacific Coast. The output of the Fushun mines, in southern Manchuria, has gone as far south as Colombo and India, at the same time the Japanese exporters have largely monopolized the markets in the territory around the Malay Peninsula and in the Philippine Islands.

Philadelphia, Penn.—The injunction proceedings brought in the Court of Common Pleas No. 5 by the Eastern Pennsylvania Co. against the Lehigh Coal & Navigation Co. to restrain the latter from shutting off a water supply from its canal, resulted in a dismissal by the court of the plaintiff's suit. The injunction was contested on the grounds that the power company had no right to a supply of water for condensing purposes, but only for the direct generation of power.

Pittsburgh, Penn.—The Epping-Carpenter Co. has been awarded the contract for 15 large power and centrifugal mine pumps by the New River Co., McDonald, Penn. Randolph & Means, Oliver Bldg., Pittsburgh, Penn., are the consulting engineers. This is the first important high-class installation of efficient deep-mine pumps in the New River district. It embodies a number of novel engineering features that will be of considerable interest to coal operators and mine engineers.

Toronto, Canada—A charter has been obtained by the Pacific, Peace River & Athabasca Ry. Co., for the construction of a line 1500 miles in length, from the mouth of the Nass River, north of Prince Rupert, B. C., eastward through British Columbia and the Peace River country to Prince Albert, Sask., which will open up an extensive coal and mineral area. The chief promoter is D. A. Thomas, of Cardiff, Wales, who proposes to tap the coal deposits more particularly the smokeless-coal areas of northern British Columbia, for the supply of the British navy on the Pacific Coast.

Washington, D. C.—It has been suggested that the situation which might be created, should the plans of various representatives from Pennsylvania, Kentucky, West Virginia and Virginia, to have American coals handled exclusively on the Panama Canal Zone materialize, would cause possible international complications. The plan suggested is to handle American coal only to the exclusion of that of all foreign countries. Under no circumstances, however, will anyone, except the United States, be permitted to control the bins or own any machinery used in coaling ships, as this government has built and owns adequate apparatus of this type.

Hazard, Ky.—At the instance of the leading coal operators and other business men in this vicinity, a bill has been introduced in the Kentucky legislature for the purpose of making Hazard a city of the fourth class, as the town now has more than 3000 inhabitants, with fine business buildings, a $30,000 school, a water-works system, and other metropolitan features. The desire for other improvements, which can be handled much more easily by a city, is responsible for the bill referred to, and it is expected that there will be no opposition to the enactment of the measure.

Coal Trade Reviews

General Review

Heavy snow storm fails to create any activity in the wholesale trade. General tendency is toward lower prices and there is considerable anxiety over the future. Adjournment of the Philadelphia conference stiffened up the market in some districts.

The heavy storm the early part of the week created some uncertainty in the hard-coal market. Prices are fluctuating sharply, and all prompt cargoes available are commanding premiums, due to the slow movement. Although the tendency is undeniably toward a lower price level, the recent severe weather has undoubtedly served to clean up the winter stocks which dealers were beginning to look forward to carrying over into summer. While this will not serve to stimulate immediate business, it will create a more active market when the discount goes into effect.

The bituminous market experienced practically no benefit whatever from the storm while the return of warmer weather has developed further weak spots, and there is a good deal of anxiety over the future. In spite of attractive bargains being offered, the business is unsatisfactory, although some small improvement is noted in the jobbing trade with quotations fairly steady. Reports regarding contracts for the new year are of a conflicting nature. A number of contracts are said to have been closed at concessions on last year's prices, but a more authoritative statement is to the effect that one of the largest bituminous companies has covered practically its entire tonnage on the same basis as last year; in spite of the relatively profitable figures of last year, there seems to be a tendency on the part of the operators to hesitate over closing at these prices, regardless of numerous opportunities to do so.

Quotations are being more stiffly held in the Pittsburgh district, due to a heavier consumption as a result of the colder weather, and also a slightly increased demand from manufacturing sources; operations still continue heavily curtailed, however. A generally better feeling in trade circles, together with the proximity of a possible suspension, has strengthened up the situation in Ohio, and caused an increase in the demand all along the line. The colder weather has enabled dealers to clean up their stocks, while demurrage coal has disappeared almost completely.

The freezing weather has grealy handicapped handling coal at the Hampton Roads piers, with the result that shipments were only fair last week, though increasing toward the end; spot sales continue light, although it is believed that the circular is being firmly held.

A materially stronger situation is noted in the Middle Western market. Mines are only waiting an improvement in transportation conditions, which were nearly demoralized by the recent heavy storm, until they open up full blast. The market was particularly benefited when it was known that the delegates to the Philadelphia conference had failed to reach an agreement and adjourned. This resulted in considerable heavy buying for storage purposes, which, if continued, will create an advance in prices. The renewed activity has injected a better tone generally into the trade, and there is a more hopeful outlook on contracts for the new year.

EASTERN MARKET

BOSTON, MASS.

Soft spots in bituminous appear with the milder weather. Contract basis also shaded. Buyers not much aroused over possibility of suspension in Pennsylvania. Favorable prices held on preferred Pennsylvania grades. Georges Creek firm. Anthracite demand good. April prices announced.

Bituminous—Some soft spots have appeared with the slump in the weather. Certain of the Hampton Roads shippers are shading prices radically in order to make spot sales, as low as $2.70 having been quoted f.o.b. for some of the brands. The contract figure has also been shaded in several instances, and there is a good deal of anxiety over the price outlook. Some fair sized mill contracts have been placed the past week and in each case it is believed at a material concession from $2.85. Obviously the curtailment has not been heavy enough. There is an evident determination on the part of some of the New River shippers to regain tonnage they have lost in other seasons and the campaign is expected to get pretty active in the course of the next few weeks.

Distribution business at points like Boston and Providence continues to show improvement. The smaller consumers find their reserves much depleted by the severe winter and there is a steady demand that keeps quotations on a satisfactory basis.

The possibility of a suspension in the Pennsylvania districts Apr. 1, is not having much effect on the market here. Buyers apparently reason that there will be plenty of coal in any event and they decline to be hurried.

Only a small tonnage of the Pennsylvania grades is coming forward for the tide-water market, and this is pretty well restricted to the quality coals. A better movement is looked for during March, especially if the labor situation looks at all threatening. The favored grades are holding well up on price and $1.50@1.60 at the mine is frequently heard as a season basis. If the mining dispute is settled early these coals will probably hold the tonnage they have gained the past two years.

There is no news on Georges Creek. While output is under curtailment shipments are being made regularly to all points and with prices characterisitically well maintained.

The loss of another coal schooner this week serves to call attention again to the rapid passing of this type of coastwise transportation.

Anthracite—Orders are fairly plentiful for March. Stocks are low in all directions and the outlook is excellent for spring business. The Maine ports that open to navigation early in April are already having supplies railed in from Portland.

Certain of the companies have already announced April prices. Those shippers who did not last year assess the Pennsylvania state tax are now adding a flat 10c. to their last year f.o.b. basis. With a 50c. water freight, upper New York ports to Boston, the price delivered alongside Boston will therefore be $5.35 for stove and egg, $5.60 for chestnut, and $5.10 for broken. Loading at New York has been slow, both on account of ice at the piers and an actual shortage of sizes like broken and stove.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.60	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.85	2.92@3.02	
New York*	2.50@3.05	2.80@3.15	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.70@2.85
Boston†				3.73@3.83
Providence†				3.68@3.83

*F.o.b. †On cars.

NEW YORK

Heavy storm ties up transportation the first of the week. Anthracite prices erratic. Surpluses being cleaned up. Bituminous continues heavy.

Anthracite—As a result of one of the worst snow storms in a quarater of a century, occurring just as New York was recovering from the effects of another storm of severe proportions, the hard-coal market is fluctuating uncertainly. Fortunately the latest storm was not accompanied by particularly low temperature. Prices were erratic and fluctuating over a wide range during the early part of the week, spot cargoes being particularly short and commanding a premium. With the crack trains on all the trunk lines running fifteen hours late and all passenger service cancelled over twenty-four hours on the Pennsylvania R.R., the movement of coal was naturally at a complete standstill.

One of the chief advantages of the severe weather on the wholesale trade will be to promote a greater activity in the domestic business after the Apr. 1 discount goes into effect.

The recent heavy demand upon dealers and jobbers will clean up stocks which dealers feared they would have to carry over. Work in the mining regions was restricted somewhat by the holiday last week and some companies also curtailed still further, but mining will probably be up to the full limit of the car supply throughout the current week; with the congested condition of the railroads, however, this will not amount to the full rated capacity by any means.

Although official announcement has as yet not been made, it is understood generally that the circular price on the upper port junior grades, that is those below pea coal, will be advanced 5c. per ton when the new circular goes into effect Apr. 1, this increase being made to carry the new 2½% Pennsylvania state tax. The companies are also notifying many of the large consumers that their allowances on contracts for the steam grades will be materially cut during the new year, this probably being done to secure additional tonnages to apply in the more profitable line trade. The market was exceedingly erratic and uncertain over most of the week, but is probably quotable on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00	$4.60@5.10	$5.05	$4.55@5.05
Egg	5.25	5.25@5.35	5.30	5.10@5.30
Stove	5.25	5.20@5.35	5.30	5.15@5.30
Chestnut	5.50	5.45@5.55	5.55	5.35@5.55
Pea	3.50	3.60@3.75	3.50	3.35@3.75
Buckwheat	2.75	2.75@2.90	2.70@3.45	2.50@2.90
Rice	2.25	2.25@2.35	1.95@2.20	1.90@2.20
Barley	1.75	1.75@1.85	1.70	1.60@1.80

Bituminous—If the recent storm had occurred two months earlier it would have had a beneficial effect on the soft-coal market. As it is, it has only served to cause a great deal of trouble with delayed shipments and other difficulties of all kinds in transportation. In fact, conditions are so unsettled that some operators are encountering both embargoes and demurrage, a rather unusual situation. Operations in the mining fields were, of course, up to the full limit of the car supply during the entire week, but this was far from being the full capacity of the mines. However, there would not have been sufficient demand to justify full operation in any event, and the curtailed production is not liable to result in a shortage.

Some activity in contracts for the new year is being noted, one of the largest companies in the local market having covered most of their production for the year. It is claimed that this business was done at the same relatively high price level as last year; in fact it appears that all companies could contract on this basis if they so desired, but prefer to hold off for the time being.

Prices are fluctuating over wide range as a result of the delays in transportations, but are still nominally quotable on the same basis as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.75@2.80; best Miller Pennsylvania, $3.10@3.15; George's Creek, $3.15@3.25.

PHILADELPHIA

Improved conditions still continue in anthracite. Tidewater business flat, but local demand satisfactory. Bituminous shows little improvement. Demurrage coal cleaned up and curtailed operations keeping output within requisitions. Prices erratic, with tendency to lower levels.

Anthracite—Conditions favorable to the consumption of anthracite still prevail in this locality. All the dealers report trade satisfactory, with duplicate orders coming in, deliveries rather uncertain, owing to the streets being filled with ice and snow. Both the wholesale and retail trade look forward to an unusually satisfactory March. Many dealers have disposed of stocks, which they were fearful of being compelled to carry over into April, and as a result, the wholesale market reflects this in an increased demand. The heavy storm early in the week delayed deliveries and enforced curtailment of work at the mines, owing to the men not reporting for work. The steam sizes are in particularly good demand.

Bituminous—There has been no marked improvement in the bituminous situation. It is understood that most if not all of the demurrage coal has been disposed of, at prices which will about pay demurrage, leaving little for the coal. Owing to curtailed production, the output is being absorbed, in most cases, but it is usually the case that the order must be in hand, before the coal is started to cover it.

BALTIMORE

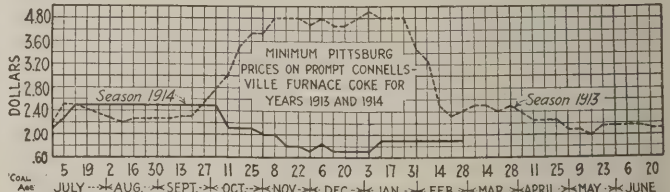
Soft-coal conditions still unsatisfactory. Anthracite domestic sales large, but light on manufacturing.

The bituminous market here remains unsatisfactory from almost every angle, although there is a note of encouragement in inquiries concerning contract business for the year to come. Spot demand is poor despite attractive bargains that are offered. Considerable coal is reported on track that is not covered, and the outlook for more congestion at tide and on mine sidings is apparent even to the causual observer. Pennsylvania steam coals of the better varieties are in the best demand. Highest grades are only bringing from $1.20 to $1.25, however, and the scale runs down to 90c. in some cases. West Virginias are weak, the better class steam coals being offered at 85c., while gas fuels of the state are down to from 65 to 80 cents.

Loading at the local piers for foreign delivery has been fairly steady. The first part of the week saw considerable trouble in making the loading points by reason of unusually heavy ice in the approaches. Trouble with frozen coal in the cars proved a handicap during the entire week.

The largest anthracite sales of the winter were probably recorded. Every householder seemed to be short of fuel at one time. Those who had depended on going through a warm winter on a shortened supply, were disappointed when the 8° temperatures arrived. All classes of fuel were in call, and there was trouble with delivery between yards and houses, because of urgency of orders. Fortunately there was little or no trouble in the handling of supplies from mine to yards.

An element of much interest to the trade was the announcement that the Baltimore & Ohio R.R. expects to build another giant coal pier here, to be constructed of steel.



CENTRAL STATES

PITTSBURGH, PENN.

Almost certain prospects of mining suspension for six weeks or longer. No agreement at Philadelphia and no second conference arranged. Coal demand improved by cold weather, producing firmer prices but no heavier operation. Coke slightly firmer. Some stock coke moved.

Bituminous—Last December these reports indicated the prospect that there would be a suspension of mining for six weeks or longer, after the termination of the present wage scale, Mar. 31. There is no reason now to depart from that view. Recently there seemed to be prospects of "continuous operation" pending settlement, but the operators have proved firm in their stand that continuous operation must be coupled with an agreement to submit all the issues to arbitration if an agreement cannot be reached by conference, and it now seems clear that the miners will not submit to this condition.

On the one hand the miners do not want arbitration while on the other hand the operators do not want continuous operation if it is coupled with the prospect of a strike or suspension later, for that would throw such suspension into the lake-shipping season. The Philadelphia conference has adjourned without accomplishing anything, just as was expected. A further conference has not been arranged and it is not even known where it will be held, except that it will probably be at Pittsburgh, Cleveland, or some other point in or near the districts affected, rather than in the East.

The operators appear to be absolutely determined that there shall be no advance in wages, also that the checkoff be discontinued, while as to the Pittsburgh district the attitude is firm that payment must be on a screened and not a mine-run basis. The lake shippers insist that they cannot have the mine-run basis when they are in competition with the nonunion districts for this trade.

The coal market has improved somewhat, chiefly on account of extreme cold weather throughout the consuming markets served by the Pittsburgh district. There is a slight increase in demand from manufacturers and there are some signs of slightly greater demand from railroads, the latter for stocking purposes against a suspension. Mining operations have not increased, being still at 50 to 60% of capacity, but prices are more stiffly held, and the market for spot shipment is quotable at the full circular basis. Some of the operators are beginning to negotiate for contracts for the year beginning Apr. 1 and on this account are particularly interested in seeing prices maintained. The cold weather and heavy snow have interfered somewhat with railroad movement, but in general merely to lengthen the movement rather

than to curtail loading, though here and there slight car shortages have been reported. Circular prices remain: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The Maryland Steel Co. is understood to have purchased 10,000 tons of March furnace coke from each of two interests at $2, and to be in the market for second-quarter coke, but unwilling at this time to pay prices asked, generally above $2. There is a little more March coke to be bought by a few consumers, but negotiations have been proceeding slowly. A few lots of prompt coke have sold at $1.90 and $1.95, but as a rule prompt coke of standard grade is $2. The extreme cold weather and heavy snow has delayed delivery of coke and an unusually large tonnage is in transit, but this condition has not caused much increase in demand for prompt. There has been an increase in the offering of soft coke and high sulphur coke, at considerably below $2. The market stands quotable as follows: Prompt furnace, $2; contract furnace, $2@2.10; prompt foundry, $2.40@2.60; contract furnace, $2.40@2.60, per ton at ovens.

The "Courier" reports the production of coke in the Connellsville and lower Connellsville region in the week ended Feb. 21 at 303,160 tons, an increase of 2910 tons, and shipments at 324,170 tons, an increase of 23,920 tons. The preponderance of 21,010 tons in shipments over production is attributed to the movement of 20,000 tons of stock coke by the H. C. Frick Coke Co., the Steel Corporation subsidiary, as this latter is continually blowing in additional furnaces.

BUFFALO

Anthracite still strong, but not expected to continue so. Bituminous doing somewhat better. Coke still slow.

Bituminous—There is something of a stir in bituminous coal. The demand is not brisk, but slack is moving quite satisfactorily. Consumers are buying heavily of slack, and seem willing to pay a good price for it. The meetings to be taken up at once at DuBois in the Allegheny Valley are expected to further emphasize the fact that the miners and operators are not going to reach an agreement right away. This is really what the operators want and the Buffalo trade is so sure that nothing will be accomplished that they are ignoring the meetings. The plan is to shut down on Apr. 1 anyhow. Even if there are no disputes with the men there are always many repairs to make which will keep the mines idle until there is again something in coal.

It is not likely that the improved demand for coal will oblige many of the mines to remain at work and the consumers are beginning to realize that coal will be decidedly scarce if the operators stick to their present plan long enough. It is in reality the only chance of bringing prices back to a paying basis.

Bituminous prices are somewhat stronger on the basis of $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.25 for slack, with the latter much more active than the sizes. There is a fair demand for Allegheny Valley coal, with slack about on a par with Pittsburgh and sizes about 5c. lower.

Coke—All effort to create a stir in the coke market has failed. The demand is not equal to the natural supply and the members of the trade say that the furnaces must run more actively than at present before there is any improvement. Prices continue to be based on $4.50 for 72-hr., Connellsville foundry, with stock coke rather scarce.

Anthracite—The demand is good. Shippers do not report such a rush as took place at the beginning of the cold spell, but February will be recorded as a good anthracite month, making up in large measure for the slackness in the early part of the winter. There is no movement in coal loading in the harbor. The shippers have no surplus and may not do any further loading until well into March, especially if there is prospect of a considerable surplus at upper lake points on May 1.

COLUMBUS

Buying increasing and price-list well maintained. Tendency on the part of large steam users to stock up. Predictions of a suspension running from 30 to 90 days. The severe snow-storm delays the movement.

There is a better feeling in coal circles generally, due to the increased demand for all sizes and the proximity of the expected suspension. Prices at the circular figures of Jan. 15 are holding well and there are few cases of cutting to dispose of stocks; demurrage coal is gradually disappearing from the market. Operators are expecting a better trade from now on, especially for stocking purposes.

It is almost a foregone conclusion that there will be a suspension of from 30 days to three months and this fact is beginning to be realized by large steam users. As a consequence they are placing orders for stocking purposes and this business is expected to be one of the big features during March. Railroads have already stocked up and are gradually accumulating surpluses for at least 60 days.

The domestic demand is one of the features of the market. Dealers have been enabled to move their large stocks and in some cases were compelled to place small additional orders. While they are still inclined to "clean up" rather than to stock up, still they have been compelled to buy to a certain extent. They have had a good demand for the better grades such as Pocahontas and re-screened varieties. The icy streets have made it difficult for dealers to make time in deliveries. This fact has mitigated against a larger volume of trade.

Operations have increased, but congestion on all coal-carrying railroads has had a bad effect. The Hocking Valley reports about 70% of normal and the domestic fields of Jackson and Cambridge report about the same. In eastern Ohio where the car shortage, caused by the severe snow storm was the worst the output was only about 55 to 60%. In the Pomeroy Bend field it was about 85%.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50 @ 1.40	.....	$1.50 @ 1.45	$1.50 @ 1.40
¾ inch	1.35 @ 1.30	$1.20 @ 1.15	1.35 @ 1.30	1.35 @ 1.30
Nut	1.25 @ 1.20	.....	1.30 @ 1.25	1.25 @ 1.20
Mine-run	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack	0.80 @ 0.75	.....	0.85 @ 0.80	0.75 @ 0.70
Coarse slack	0.70 @ 0.65	1.00 @ 0.95	0.75 @ 0.70	0.65 @ 0.60

CLEVELAND

A recurrence of stiff winter weather and light receipts of coal gave the market a stronger tone. Fairmount operators have sold large tonnages at low prices the last week for delivery up to Apr. 1. Semibituminous domestic coals are in good demand.

The rough weather of the last two weeks caused a lighter production of coal in Ohio, which was felt at the opening of this week.

Middle district operators are holding coarse coals at an advance of 10c. over the spot market, while No. 8 operators are asking $2.05 f.o.b. Cleveland, for three-quarter coal. Ohio producers are looking for higher prices up to Apr. 1, when they fully expect the mines to close temporarily.

Fairmount operators have sold large tonnages of three-quarter coal for delivery during the next thirty days at 75c. at the mines or $1.90 f.o.b. local yards. The West Virginia agencies are so anxious to sell that they have given options on tonnages of 75,000 to 100,000 tons for shipment in equal weekly amounts up to Apr. 1. The options were for a week and expired Mar. 1.

The demand for Pocahontas lump and egg is brisk and retailers have been running low on these coals. Hard coal is plentiful, but not so much so as to become a burden on the market. Dealers are taking just enough to fill immediate orders. The demand for anthracite will not be heavy until the last of the month when shippers will begin to place coal at the summer circular. The old stocks will be well cleaned up.

Spot sales Monday were 5c. higher on many grades of coal as compared with Friday and Saturday of last week. Spot sales at the opening of the week were as follows:

	No. 8	Middle District	Pocahontas
Lump, 1¼ in.	$2.00@2.05	$2.00@2.20	$3.60@3.65
Lump, ¾ in.	2.00@2.05	1.95@2.05	
Egg	.....	.....	3.60@3.65
Mine-run	1.90@1.95	1.85@1.90	2.75
Nut	1.95@2.00	1.95@.200	
Slack	1.95@2.00	1.85@1.90	2.60

DETROIT

Colder weather has cleaned up the surpluses. Movement somewhat delayed.

Bituminous—There is little free coal on track and the surplus is reduced to the minimum. The movement during the past week has been heavy, although the situation cannot by any means be described as active there is nevertheless a large number of inquiries which will result in a heavy volume of business. Cars are in full supply, but the movement from the South has been temporarily delayed by the heavy weather.

The colder weather arrived too late to be of any great benefit to operators, the spring discounts now being too near at hand, but nevertheless it is resulting in a sharp decrease in the supplies of domestic coal on hand. With the market heavily congested with coal this is coming as quite a relief. Steam coal seems to be about holding its own at a relatively low level. One of the adverse conditions in the local situation is the tendency on the part of some agencies to force business by offering ridiculously low prices. Such a condition usually prevails with the approach of the spring discount period, but it seems to be particularly aggravated at the present time. Slack coal is under particularly heavy pressure.

Anthracite—With large consumers compelled to wait their turns for shipment, the situation in anthracite has taken a decided turn for the better, and indications are that the jobbers will now be able to clean up their winter supplies, and may even be forced into the market again before Apr. 1.

Coke—The coke market has improved, Connellsville now being quoted $3, Solvay $3.25, and gas house at $2.90, all f.o.b. ovens.

HAMPTON ROADS

Week's dumpings fair. Some slight improvement in demand both coastwise and foreign.

Shipments from Hampton Roads have been fair, the heaviest movement being made toward the end of the week. Weather conditions have greatly handicapped dumpings at the piers the coal being badly frozen in the cars and requiring considerable extra labor to get it out.

Spot sales still continue light and while there have been a few large sales suppliers decline to say at what price shipments were made. It is claimed, however, that there has been no cut in the circular price of $2.85 per ton on the run-of-mine Pocahontas and New River.

Export shipments for the week have been to Genoa, Rio de Janeiro, Havana, Kingston, Canal Zone, Bridgetown, Cerea and Dakar.

While figures showing dumpings for the various piers are not yet obtainable the indications are that the dumpings for February, 1914, will fall behind the 1913 figures. It is probable that the Virginian Ry. will fall off about 45,000 tons while the Chesapeake & Ohio Ry. will practically hold its own. It is expected the Norfolk & Western will fall behind to some extent but hardly as great as the other two roads. Some of the dumpings which will be made early in March should really be credited to the February account as vessels have been delayed by the bad weather and have run over into that month when they were actually due in February. The demand, too, on account of the mild winter, has been lighter than last year.

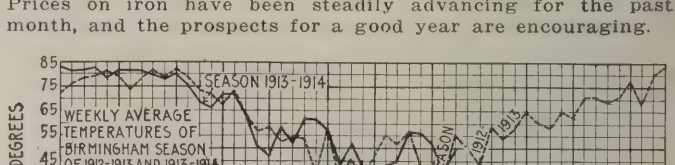
LOUISVILLE, KY.

Continued wintry weather and active domestic demand have brought the retailers into the market. Prices have not advanced, the average still ruling below circular quotations.

With unbroken winter weather lasting two full weeks, the active demand experienced from domestic consumers has resulted in a reduction of retail stocks to a point where dealers have been forced to order fresh supplies, for about the first time this winter. Retailers waited until the last possible moment in the hope that the weather would break, but were disappointed in this, and the demand for coal has been rather urgent. The operators have, therefore, again been able to resume full-time operations, and heavy shipments are the rule. Agents and traveling salesmen find orders plentiful.

While the regular circulars for March delivery have been issued, it would be difficult to find anybody who takes these prices seriously. No advance over the low prices which have prevailed lately has been made, the situation being somewhat too delicate to risk scaring the retailer off, although with the domestic demand as heavy as it has been recently, the buyer would not be inclined to quibble about prices.

The steam market is about stationary, although the greatly increased quantities of screenings now available will probably affect the market adversely. This is not evident as yet, however, the better grades of screenings being in fair demand at 75 to 85c. The renewed supply of screenings has rendered practically unsalable the mine-run coal on tracks in Louisville. This grade was shipped in to fill the gap caused by the scarcity of screenings, as well as to give the mines something to do.



SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM, ALA.

Steam and domestic coal improved slightly. Furnace and foundry coke quiet and blacksmith normal. Large sales of pig iron.

Due to the real winter weather this past week, accompanied with snow and sleet as far south as the Florida line, domestic lump coal shows some improvement, both in the volume of business and prices. Steam coal, while slightly better than for the past two or three weeks, is still far from being satisfactory, and while the prices are remaining about stationary, the orders are not coming in as fast as could be expected at this season. Blacksmith coal seems to be holding its own in a satisfactory manner. Both furnace and foundry coke are quiet, with small sales.

Furnaces again report a large tonnage of iron sold, with prices pushing the $11 mark for 2 Foundry, f.o.b. Birmingham. Prices on iron have been steadily advancing for the past month, and the prospects for a good year are encouraging.

NEW ORLEANS

Coldest weather of winter brings wave of good business. Reduced prices still apply. Large consumers believe bottom has not been reached and are withholding purchases.

Descent of the coldest weather of the winter last week helped materially in the moving of the large piles of coal, which, it was feared, would have to be carried over. Stocks are still too large for this season and the recent price cut is still in force; the fact that the larger consumers do not believe that the bottom has been reached is retarding any heavy purchases of coal at this time.

Never before has the efficiency of motor-driven delivery been proven so satisfactory. With the coming of the cold weather orders appeared in such numbers that no dealer was able to handle all the business promptly, but those having auto trucks saved a good percentage of their costs owing to the rapidity with which the deliveries were made.

This late in the season the cold weather came as a surprise and most of the orders were small; it was not unusual to have to deliver three separate orders to the same house. Orders were accepted only on the basis of sidewalk delivery. During the past two weeks more coal has been delivered in the city than ever before in the same length of time.

INDIANAPOLIS

Snow blockade interferes with freight traffic on railroads, causing mines to fall behind on orders. Situation being rapidly relieved. Severe weather cleaned up stocks of Indiana coal, but Eastern supplies hold out. Railroads and factories stocking up. Prices generally unchanged but satisfactory. Demand for screenings and steam grades not well supplied.

Indiana mines will run full schedule as soon as railroads can handle mine shipments. The blockade by the heavy snow has been such as to almost shut off freight traffic. Mines have plenty of orders. Retail yards have been well cleaned up of Indiana coal during the zero temperatures of the last two weeks. The mines are far behind orders, but expect to catch up rapidly when the car situation is relieved, as the roads promise to give this traffic special attention. Users of screenings and steam grades have been rather scantily supplied.

During this stress of heavy consumption, the demand for Eastern coal has been satisfactorily filled, due to the large stocks piled up in the fall. Indiana coal cannot be stored this way and it has been difficult for retailers to keep up supplies. Railroads and other large consumers of steam grades have continued to stock up against any shut-down, should the operators and miners fail to reach a wage agreement. February was by all odds the best coal month of the season, but March promises to be equally as good. Prices have not been advanced, but mines are getting top figures. Where a buyer has to go to the open market he has had to pay a slight premium the last few weeks. Generally speaking there has been no quotable change either at the mines or yards.

CHICAGO

Continued cold weather and severe storms throughout Illinois and Indiana result in a considerable improvement. The possibility of a mine suspension also helped support the market, dealers taking advantage of present conditions to stock up.

A large factor in the market was the disposal of demurrage coal, but this centered principally around low priced fuels. While obtaining closer to circular prices than for the last two months, producers see no prospect of any increase in the circular. As the result of a limited supply of fine coal, screenings are approaching the mine-run price, there having been an increase of from 5c. to 15c. a ton and the upward trend still evident.

Storage piles of retailers are rapidly being depleted and there is need for additional coal to carry them through March, but they desire to start April with a new stock. This condi-

tion of affairs means that dealers are willing to take 30- or 35-ton cars, but not more unless the April discount be attached to at least a part.

Improvement is seen in the Hocking situation with the demand accelerated by the cold weather. Prices are steady at $1.50 a ton. Some anxiety had been felt regarding the splint situation owing to the fact that Eastern operators persist in sending stock in large open cars whereas the demand is for small cars. With a cleaning up of accumulations, however, conditions have become better with prices at from $1.25@1.40 a ton. Conditions are somewhat better in the Franklin County field and the Carterville market with the recent low prices withdrawn. An improved demand for domestic coke resulted in a stronger market.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.07@2.17	$2.55@2.65	$2.12@2.27	
Steam lump	1.97		1.97	
Egg		2.55@2.65		$4.30
Mine-run	1.87	2.20@2.25	1.87	3.45
Screenings	1.67	1.90	1.62	

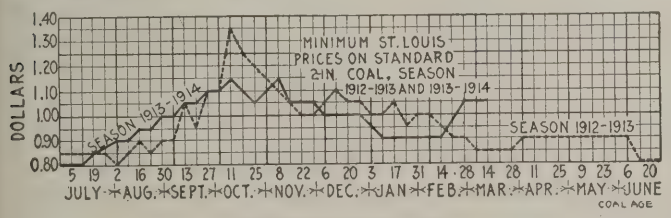
Coke—Connellsville, $5.25@5.50; Wise County, $5@5.25; by-product, egg and stove, $4.90; byproduct, nut, $4.75; gas house, $4.50.

ST. LOUIS

Improved tone in the local market. Large operators attempting to keep the mines working. Considerable buying in anticipation of a suspension.

The local market is in an optimistic mood at this time and has been since the conference adjourned at Philadelphia. The big operators of St. Louis do not want a strike or suspension as they hope to force the little operator out of the coal game. This seems to be the general opinion. The little operator, however, is playing his hand well and will force a suspension if such a thing is possible.

During the past week between four and seven hundred cars of railroad coal was purchased over and above regular requirements. A few steam plants have put in from ten to forty cars for storage coal, but there was no general demand up to the early part of the present week for storage coal.



By Thursday or Friday it is likely that the market will rise considerably on account of the concentration of buying power. This is explained by the fact that big companies are buying in five- and ten-car lots in order to keep the market from getting away from them. So many companies practicing these tactics will have the same effect as if they went into the market and bought their entire requirements.

Screenings are still in good demand, Carterville at from 75c. to 80c. with chances of going to $1, and Standard at about 60c. to 70c. and lined up for an advance. The sized coals have not changed much since last week, but the market is liable to take an upward turn daily, and for that reason a conservative price list is maintained.

There is no demand for smokeless, coke or anthracite. The washed market is strong on Nos. 3, 4 and 5, with little demand for Nos. 1 and 2. There is a car shortage to some extent on the C. & E. I. and I. M., but nothing serious. Movement of coal is better and transportation facilities easier.

The market continues quotable as follows:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	.....	.....	.....	$1.05 @ 1.10	$1.15
3-in. lump	.....	.....	$1.40	.....	.....
6-in. lump	$1.25 @ 1.50	.....	1.50	1.25 @ 1.35	1.25
Lump and egg	1.85 @ 2.15	2.15	.....	.....	1.15
No. 1 nut	1.20 @ 1.40	.....	.....	.....	.....
Screenings	0.80 @ 0.85	.....	.....	0.55 @ 0.60	0.60 @ 0.65
Mine-run	1.10 @ 1.20	.....	.....	.....	.....
No. 1 washed nut	1.50 @ 1.60	2.25	1.50	.....	.....
No. 2 washed nut	1.25 @ 1.35	.....	1.25	.....	.....
No. 3 washed nut	1.25 @ 1.30	.....	.....	.....	.....
No. 4 washed nut	1.25 @ 1.30	.....	.....	.....	.....
No. 5 washed nut	0.75 @ 0.80	.....	.....	.....	.....

KANSAS CITY, MO.

Return of milder weather and mine operations have again slackened up. Market steady but at a relatively low level.

Mining operations in the Southwest have again slackened somewhat after a brisk month. The weather has taken a turn for the better, from the standpoint of the consumer, and coal is moving correspondingly slower. The end of February saw a shortage of cars, due partly to the heavier movement, but chiefly to a blizzard which swept through the Southwest, demoralizing transportation. The trouble was short-lived and caused only temporary inconvenience.

Mines are now producing about 75% capacity, and the market is steady at bed-rock prices.

PORTLAND, ORE.

Mild weather continues and demand for coal remains light. Hopes are entertained that railroads will grant reduction in rates to Portland.

This is about the mildest winter experienced in the Pacific Northwest for many years and consequently the demand for coal for domestic purposes has been and still continues light as compared with former winters. Only for a few hours has the thermometer dropped to the freezing point and there has been practically no snow. The dealers, however, say that while the consumption per capita has been light this winter, it is steadily increasing on the whole, and this in spite of the rapid introduction of fuel oil.

PRODUCTION AND TRANSPORTATION STATISTICS

Suspension Docket No. 331—Alexandria, Va., switching Charges.

Proposed increase in the switching charges on coal and coke by the Southern Railway Co. from the Potomac yard, near Alexandria, Va., to Alexandria proper, not justified, but a maximum charge of 20c. per net ton established for the future.

BALTIMORE & OHIO

The following is statement of coal and coke tonnage moved over this system and affiliated lines during the month of January, 1914, and for the corresponding month of the previous year:

	1914	1913
Coal	2,917,834	3,003,404
Coke	274,955	439,176
Total	3,192,789	3,442,580

PENNSYLVANIA RAILROAD

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for January of this year and last year in short tons:

	January	
	1914	1913
Anthracite	915,027	1,014,259
Bituminous	4,117,514	4,210,196
Coke	853,412	1,288,514
Total	5,885,953	6,512,969

NORFOLK & WESTERN

The following is a statement of the tonnage shipped over this road during January, as compared with corresponding period of 1913 in short tons:

	January	
Coal	1913	1914
Tidewater, foreign	144,062	151,315
Tidewater, coastwise	308,918	337,654
Domestic	1,616,894	1,364,229
Coke		
Tidewater, foreign	143,196	114,776
Domestic	5,055	.....
Total	2,218,125	1,967,974

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Feb. 14, as follows:

	Surplus	Shortage	Net*
New England Lines	2,313	0	**2,313**
N. Y.; New Jersey, Del.; Maryland; Eastern Penn.	20,190	0	**20,190**
Ohio; Indiana; Michigan; Western Pennsylvania	39,580	0	**39,565**
West Virginia, Virginia, North & South Carolina	4,982	15	**4,982**

***Bold face** type indicates a surplus.

GREAT LAKES

The "Marine Review" reports the gross coal trade on the Great Lakes for the past three years as follows in short tons:

	1911	1912	1913
Anthracite	3,917,419	4,204,741	5,033,696
Bituminous:			
Pittsburgh, district	10,611,941	11,300,000	13,415,473
Ohio	4,019,544	4,676,000	6,176,624
West Virginia	7,151,200	7,360,000	8,736,586
Total bituminous	21,782,685	23,336,000	28,328,683

The total of all kinds in 1913 was 33,362,379 tons, which is the heaviest season business ever reported. The Pittsburgh district kept its position as the leader in supplying Lake coal.

IMPORTS AND EXPORTS

The following is a comparative statement of imports and exports in the United States for December, 1912-13, and for the 12 months ending December, 1911-12-13, in long tons:

	12 Months			December	
Imports from:	1911	1912	1913	1912	1913
United Kingdom	9,278	8,697	6,141	2,403	812
Canada	980,174	1,404,139	1,096,924	109,723	116,944
Japan	16,031	30,621	117,483	4,958	18,046
Australia and Tasmania	232,969	162,671	188,613	10,743	27,859
Other countries	356	2,222	4,696	20	1,400

FOREIGN MARKETS

GREAT BRITAIN

Feb. 13—The market continues generally firm for prompt loading. For forward positions, buyers are holding off. Tonnage is being somewhat delayed by stormy weather, but at present this is not having any effect—most collieries having sufficient ready steamers to keep them fully employed. Quotations are approximately as follow:

Best Welsh steam	$4.50	Best Monmouthshires	$4.20
Best seconds	4.38	Seconds	4.05
Seconds	4.29	Best Cardiff smalls	2.73
Best dry coals	4.38	Seconds	2.52

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are net f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days.

British Exports—The following is a comparative statement of British exports for January of the last three years, in long tons:

	January		
	1912	1913	1914
Anthracite	241,924	298,308	269,871
Steam	3,945,278	4,417,993	4,231,381
Gas	827,198	901,364	885,713
Household	139,679	145,726	131,714
Other sorts	267,096	306,927	276,091
Total	5,421,175	6,070,318	5,794,770
Coke	113,871	107,095	124,256
Manufactured fuel	148,932	196,739	169,945
Grand total	5,683,978	6,374,152	6,088,971

FOREIGN TRADE OPPORTUNITIES

The United States Consular Service reports opportunities in foreign coal markets as follows; complete details regarding different items can be obtained on application to the Bureau of Foreign and Domestic Commerce, Washington, D. C., by giving numbers:

The chief owner and manager of a tramways company in a foreign country informs an American consulate that he desires to import American coal. He is chiefly interested in Pocahontas and Georges Creek coal. The inquirier uses about 1600 tons of coal annually and desires to establish coaling stations at several points. He is reported to be able to finance such undertakings, as he is the largest private employer of labor in the country in question. All communications should be addressed to the consul who forwarded the information. No. 12,513.

SOUTH WALES EXPORTS

In the South Wales ports about 35,000,000 tons of coal are loaded annually, of which more than two-thirds is handled at docks in the Cardiff customs district. The great rise and fall of tide compels all ships to enter locked-in docks; these being excavated in level plains compel the use of expensive and elaborate appliances for lifting the coal from the dock over the vessel's side to the hatchway. The haul from the mine rarely exceeds 20 miles, and the cars carry 10 to 12 tons, tare being 6 to 8. All loading appliances are fitted for these weights.—"Daily Consular and Trades Reports."

COAL SECURITIES

William J. Hoey reports the market on various coal securities for the week ending Feb. 28, as follows:

Stock	Bid	Asked	Stock	Bid	Asked
American Coal	80	95	Jef. & Cle'fd. C. & I. Pfd.	75	85
American Coal Products	83	84	Kentucky Block Cannel	40	60
Amer. Coal Prod. Pfd.	104	106	Lehigh Valley Coal Sales	185	195

No Important Dividends were announced during the week.

Central Coal & Coke Co.

President Chas. S. Keith, in the annual report for the year ended Jan. 1, 1914, says in part as follows:

During the past year we have arranged for the funding of the bills payable of the Central Coal & Coke Co., and provided for the construction of a new sawmill in Texas, by organizing the Delta Land & Timber Co. for that purpose. The coal company owns the stock of the Delta Land & Timber Co., and the Delta Land & Timber Co. in turn owns all the timber and lumber properties of the Central Coal & Coke Co. This transfer was completed in January, and will be shown on our annual statement for the year 1914.

At the present time all but $430,000 of the bills payable of the Central Coal & Coke Co. have either been paid, or we have the funds in the bank to cover payments coming due during this month, and possibly by the middle of next month the coal company will have taken care of all its bills payable.

The new sawmill will probably be in operation by January 1 next, from which time the company should take from this property in the way of earnings and depreciation an average of $500,000 per annum, in addition to its present earnings and charges.

The net earnings for the year were $544,044, as compared with $631,508 in the previous year. The comparative statement of earnings follows:

	Credit		Debit		
	1914	1913		1914	1913
Wholesale coal dept.	$490,742	$448,801	Mining dept.	.....	$33,807
Retail coal dept.	28,124	52,654	Roy cred coal lds	$126,663	107,655
Washer	3,551	18,444	Roy cred timb lds	339,865	253,678
Mining store	139,871	132,903	General expense	88,818	81,492
Wholesale lum.	305,804	363,496	Int. on bonds	72,990	78,596
Carson mill	169,275	93,586	Dep. on wash prop.	4,008	4,008
Keith mill	96,503	113,582	Dep. on mil prop	33,986	36,239
Miscellaneous	22,554	41,811	Dep. motor trucks	4,544	.....
Rentals, coal department	31,493	.....	Int. on exchange	73,041	38,291
Total	$1,287,922	$1,265,279	Total debit	$743,918	$633,770
			Net earnings	544,004	631,508

Note—For the previous annual report of this company see Coal Age, Vol. 3, p. 628.

Barsteel Heavy Haulage Locomotive

4 Features of Baldwin-Westinghouse Barsteel Electric Mine Locomotives That Assure Maximum Tonnage with Least Expense

The Cast Steel Bar Frame which gives great strength with least weight; permits easy access to, and excellent ventilation for the motors.

The Vauclain Removable Gib which greatly facilitates the removal of journal boxes and permits inspection or replacement of all wearing parts with a small cost of time and labor.

The Oil and Waste Lubricating System for the motors, with specially designed bearings for long life in service, which has been adopted as a standard after years of investigation.

The Commutating-Pole Motors which insure sparkless commutation at all loads. As a result, the commutator and brushes are long lived and require little attention, brush renewals are seldom required, and carbon and copper dust inside the motor is practically eliminated.

These features are but few of many which have been incorporated in Baldwin-Westinghouse **Barsteel** mine locomotives in order to give the user the greatest possible service. You can obtain them only when you specify Baldwin-Westinghouse.

Address either company for full information.

A Modern Pair Of Twins

The Weekly Ad-Talk Page

"In one sense, advertising and salesmanship are twin sisters. I do not know the girls apart. The one that is nearest I love best"

So says Elbert Hubbard, the man who put East Aurora on the map.

But it is only within recent years that advertising and salesmanship have gone hand in hand. Many of you can look back to the days when it was considered unethical for a reputable house to advertise —when the quacks and charlatans had it practically all to themselves.

Quite a contrast is the situation today—"Let the buyer beware" brand of advertising replaced by good honest salesmanship-advertising, the kind which not only creates the desire but which instills confidence as well.

More goods, today, are sold than are bought.

Why? Because the buyer has more confidence in salesmanship—also because the manufacturer is putting more salesmanship in his advertising copy.

And that is exactly what is making your technical journal more valuable to you—the fact that there is real salesmanship copy in the selling section.

What a slow and uncertain process it would be for you to find the right equipment for every job if you could not depend upon the printed advertisement to help you get what you want.

But you can *depend* upon the advertisers in COAL AGE. They are reliable. They could not stay in the paper if they were not. Their messages are free from misstatements, boasts, exaggerations and knocking—all of them conforming themselves to the "Hill Advertising Code," peacefully and agreeably.

Let, then, this be your first meeting place with the manufacturer who is to furnish any part of your equipment, today or tomorrow.

Pin your faith to the advertiser who stays before you *constantly* in the Selling Section of COAL AGE because *"Only reliable goods can be continuously advertised."*

COAL AGE

Vol. 5 NEW YORK, MARCH 14, 1914 No. 11

The Motive

By Berton Braley

Written expressly for Coal Age

We go below in the shakin' cage
To drill an' cut the coal,
To shoot an' load for our daily wage
An' work like a bloomin' mole,
An' why do we take the chanct of damp,
An' the chanct that the roof will fall?
An' why do we tote a miner's lamp?
Fer the wife an' the kids—that's all?

The boss he plans an' the boss he frets
At tryin' to "make her pay,"
He thinks an' schemes for the wealth he gets
From the depths of the mine each day,
An' why does he drive us for all he's worth
An swear that our work is small,
An' why does he want to own the earth?
For his wife an' his kids—that's all!

The Irish fight with the Hun and Wop
And the English scraps the Russ,
An' the oaths an' grumbles never stop
When the Finn an' the Magyar fuss,
They quarrel an' fight till heads are broke
An' the cops get a hurry call,
But they all work on till the day they croak,
For the wife an' the kids—that's all!

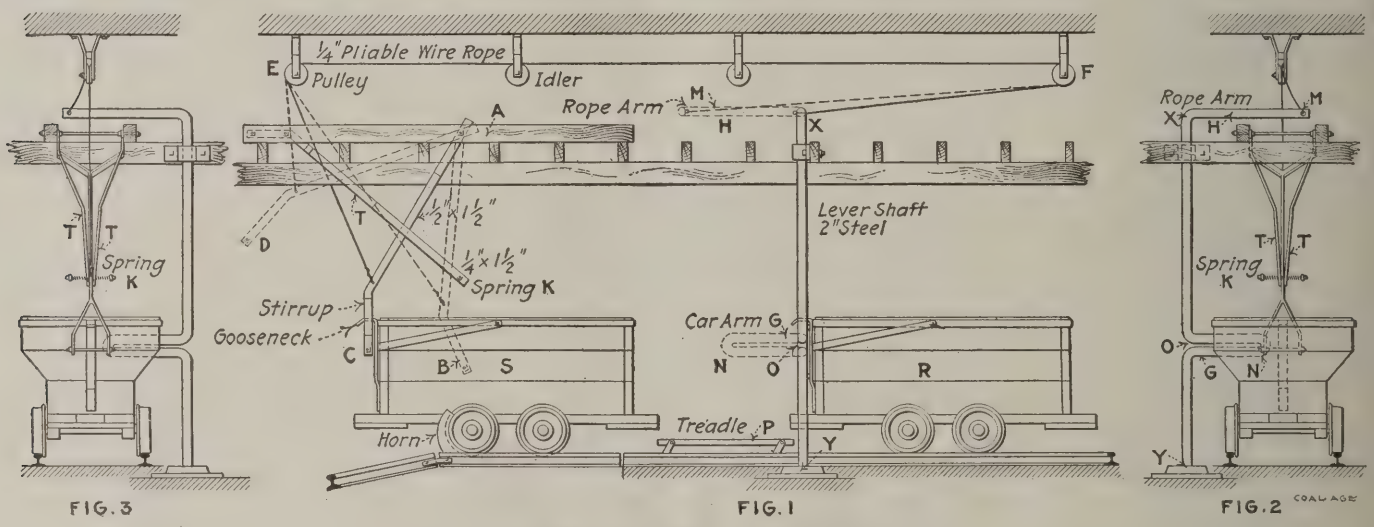
Yes, that's one way we are all alike,
Whatever the work we do,
Tony and Oscar and Hans and Mike,
Master and Miner, too,
Our job may weary us, head to feet,
An' our pay seem pretty small,
But it's all worth while when at night we meet
The wife an' the kids—that's all!

Ideas and Suggestions

Automatic Arrangement for Raising End Gates on Mine Cars

By Elkins Read*

The automatic arrangement for raising the end gates of mine cars here described has proved economical in time and labor, aside from eliminating to a considerable extent accidents at the dump.



The incoming load R, Fig. 1, engages car arm G, which projects over the track. This revolves the vertical shaft XY and rope arm MX, causing the end of the arm M to move forward to the projected position. This movement carries the rope forward as shown, pulling the stirrup AC to the position AD. Load R advances and bumps the empty car S off the dump. The car arm G meanwhile rubs along the side of the car until it is released, thus keeping the stirrup up until the empty is out of the way.

After the load R has released the lever G, the stirrup falls to the position AB, pulling the lever shaft and arm back to their original positions. As the stirrup falls to the position AB, it wedges into the straps TT, which are in turn held by the spring K. It is essential that this stirrup be in approximately the position AB and at rest when the incoming load engages it, as under this condition no matter with what velocity the car approaches there will be no disastrous results, as the stirrup will be carried along with the car and be in perfect readiness to engage the gooseneck. This enables the dump man to throw his lever and let the dump tilt at the instant that the car strikes the horns.

The exact position and size of the several parts will necessarily depend upon local conditions, such as the size of the car, etc. However, there are a few points necessary to observe in order to obtain good results. The lever shaft XY should be placed back from the dump a sufficient distance so that the stirrup will be in the position AD before the incoming load bumps the standing empty. At the same time it should be certain that the stirrup will come to rest at AB before the load R engages it.

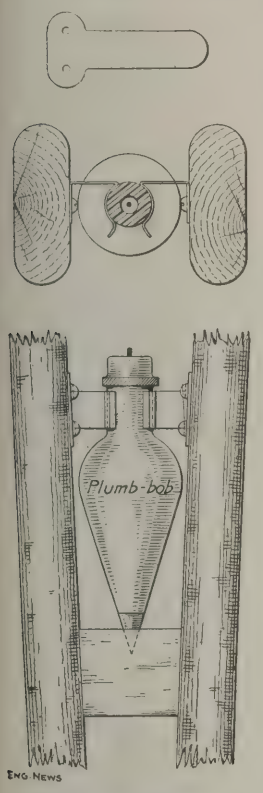
Some Details of Construction

The lever shaft should be set back about 2 ft. from the rail and the arm should be approximately 4 ft. long. The stirrup should be made about 6 ft. in length, fixing the point A about 2 ft. behind the end of the car bed and the point B, 8 or 10 in. below the gooseneck, thus allowing the dump to attain its initial momentum without undue hindrance. The rope should be of sufficient length, so that when the stirrup is in position AB and the arm MX is at right angles to the track it will be taut.

The Automatic End Gate Raiser

There should be a weak link somewhere in the rope, so that if the incoming load should strike the car arm while the dump is down, this link will straighten out and relieve undue strain, after which another one can be substituted. Placing idlers so as to carry the weight of the rope eliminates the necessity of attaching a counterweight to pull the lever arm back into position, since under this favorable condition the stirrup performs this function.

This device can be made at any mine blacksmith shop at a moderate cost. Time and money will, however, be saved by first making a rough model to be used for finding the exact length and position of the entire appliance.



An arrangement of this kind, working in conjunction with a car haul and dumping into a reciprocating hopper feeder, allows coal to be dumped and screened at the rate of six 2-ton cars per minute over a Phillipp's crossover dump.

*Mining engineer, Maryland Coal Co. of West Virginia, Simpson, W. Va.

The common practice of running electric motors and electric currents through the return air courses of dusty mines is dangerous and should be strictly forbidden.

Plumb-Bob Holder for Transit Leg

The description of a device for holding a plumb-bob, in *Engineering News* of Nov. 20 (see COAL AGE, Vol. 4, p. 898), has called forth a description of another, which the inventor, C. M. Lawrence, County Surveyor of Hughes County, Oklahoma, believes much superior. His directions are as follows:

A BRASS SPRING PLUMB-BOB HOLDER FOR TRANSIT LEG

Cut two pieces of thin spring brass (mine are cut from the shell of a discarded alarm clock) as shown in the accompanying sketch. Bend as shown, and fasten in the split leg with 3/8-in. round-head brass screws. I also cut from the same material an oval plate, and tack it on the block below with brass brads before boring the $\frac{3}{16}$-in. hole for bob point. A very light grip will hold the bob, even up to a jolt which would put the instrument out of business. No parts project. And no "trigger work."

A Useful Hitch

R. C. Hardman, Colorado Springs, Colo., sends the following description of a rope hitch, which he believes has not been described previously in print:

In tying the knot a bight is taken wherever desired, as shown in Fig. 1. Then catching the the bight at the points *a* and *b*, the bight is turned over in a direction away from the tier, so that the knot assumes the shape shown in Fig. 2. Another turn is made in the same direction with Fig. 3 as the result. These two turns are made, in practice, in one operation, Fig. 3 being merely a 360-deg. turn of the bight in Fig. 1. The line *B* is then placed beside the line *A* and the loops *a* and *b* are brought together back of the lines *A* and *B*. A hook or other fastening may then be placed in the double loop so made and a strain taken on the line *A*. The finished knot is shown in Fig. 4. Care must be taken to have the line *B* beside the line *A* or the knot will not hold. When the strain is taken off and the hook removed the knot falls apart. Its principal use is on a fall line, or any line to which power is applied, in case a temporary pull is desired at any point other than that at which power is usually applied. It may be used also in various other cases which will be obvious after the knot is known.—*Engineering News.*

Scale Removed by Graphite

The photographs show the front and back views of a piece of scale taken from the bottom front end of a 8-ft. x 30-ft. Lancashire boiler on which we have been using graphite for about three months, says E. Russell in *Power* of Mar. 3, 1914. This boiler is one of a battery of three, fed from a dirty river, the water from

A PIECE OF SCALE REMOVED BY GRAPHITE

which leaves moderately hard scale which formerly had to be chipped off, but since using graphite the boilers are as clean as it is practicable to get boilers. What little scale remains may be easily brushed or scraped off; it is not necessary to use a scaling hammer. On examining the front view it will be seen how effectively the scale has been driven off the shell plate and flues and collected in layers on the bottom of the boilers.

Some Efficient Compressed-Air Plants in Coal Mines

By S. W. Symons*

SYNOPSIS—Four plants in the anthracite region of Pennsylvania are here described which, by comparison with many installations of a similar character and made for a like purpose, may be truly said to be efficient.

Economy in the operation of machinery, like the cost of living, is rather more a question of ratios than one of absolute values. The cycle of operations in the compressed-air mining installation is so long and complex from the combustion of the fuel in the boiler furnace to the coal cutting or pumping at the working face, that from the thermodynamic standpoint no figures of high efficiency can possibly be secured.

In spite of the many losses which the ingenuity of man has never succeeded in stopping, there are numerous others which are capable of elimination either in total or in part. That installation, then, which cuts down these needless wastes to a minimum may, by comparison with other plants erected for the same purpose, be justly and rightly termed economical. It is the purpose of this article to describe four plants coming under this category which are in successful daily operation in the anthracite-coal region of Pennsylvania.

In compressed-air installations, the coal-mine operator may well profit by the experience of the iron and metal mines, where air-actuated rock-cutting machinery is a necessity and where, in most cases, economical Corliss engines or electric-motor-driven compressors are installed.

At the No. 5 colliery of the Lehigh & Wilkes-Barre Coal Co., at South Wilkes-Barre, Penn., air has been supplied for the last 8 years by an Ingersoll-Sergeant duplex compressor. This machine is provided with simple Meyer valve steam cylinders and two-stage air cylinders compressing to 100 lb. It has been kept running 24 hours a day since installation, and is now being rebuilt preparatory to being put again into regular service.

A new compressor, shown in Fig. 1, which was installed a year ago, was built by the Ingersoll-Rand Co. It is of the duplex type with Corliss steam cylinders 28 and 42 in. in diameter, hurricane air cylinders 37¼ and 22¼ in. in diameter, respectively, while the common stroke is 36 in. The capacity at 100 r.p.m. is 4206 cu.ft. of free air per minute compressed to 100 lb.

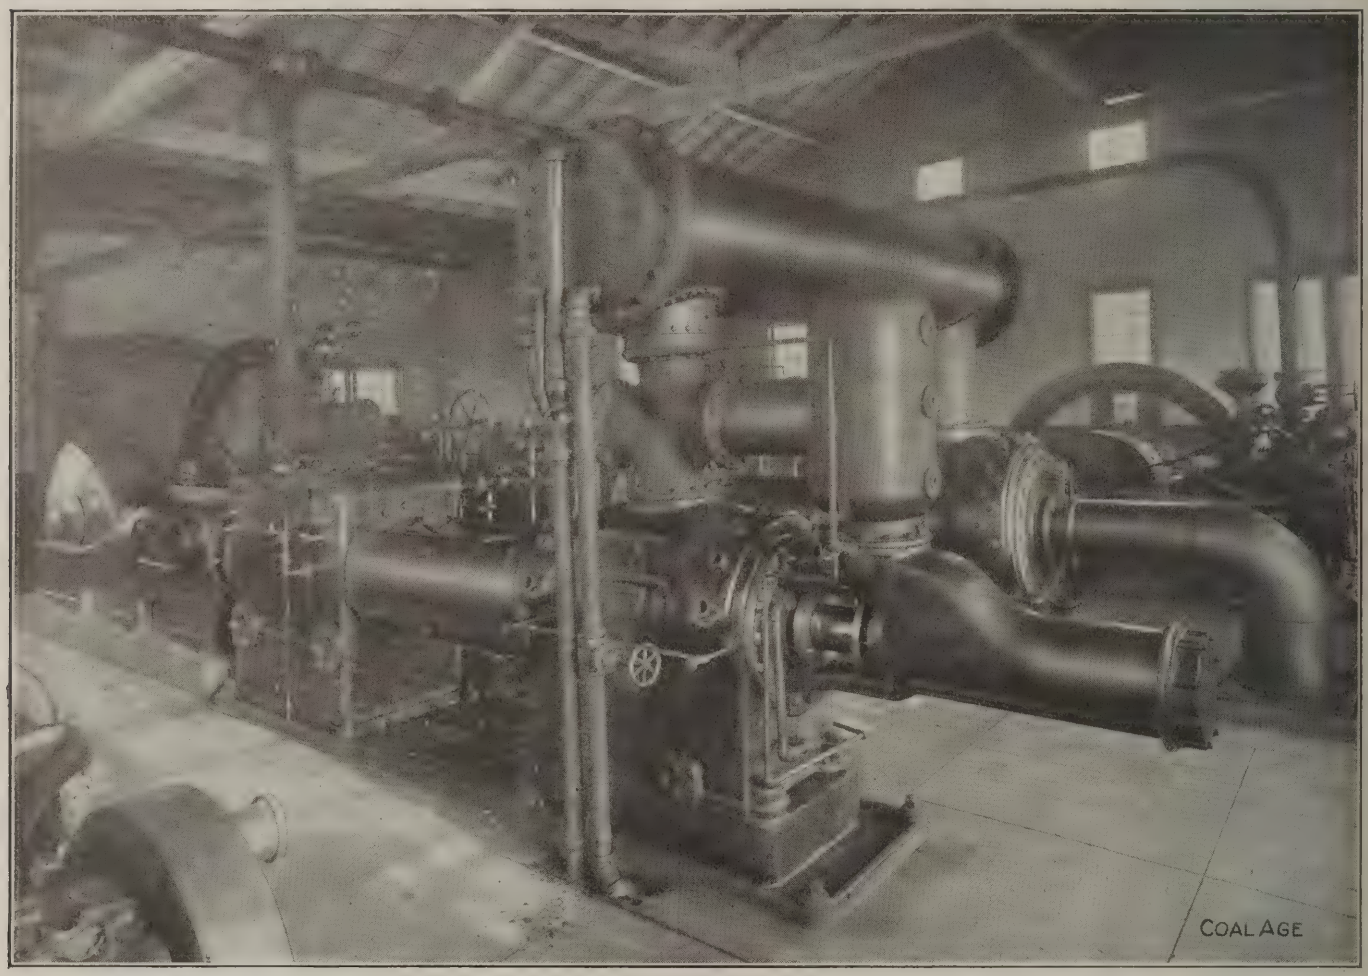

Fig. 1. Compressor Installed at the No. 5 Colliery of the Lehigh and Wilkes-Barre Coal Co.

*11 Broadway, New York.

The steam cylinders are fitted with a type of Corliss valve-gear, claimed by the makers to be highly efficient and nearly silent. This latter claim is well borne out by the smooth, quiet running of the machine, the only noticeable sound being the slight clicking of the relief gear and the sucking of the dash pot. The usual objectionable hammering of the drop rod hook on the dash-pot cover is entirely absent.

The Crank Case Forms the Oil Reservoir

The crank end of this machine, being wholly inclosed, provides a reservoir for a continuous oiling system for all the bearings except the valve-gear. This saves much time on the part of the attendant and is economical of oil, besides producing a cleanly machine with pleasing lines.

The air-valve gear is of a well known but unique type. The inlet air is drawn from a conduit beneath the engine-room floor through a hollow piston rod into a hollow piston, each face of which contains a valve of a continuous-ring form. These valves travel backward and forward with the piston and are opened and closed by their own inertia, consequently there is an entire absence of outside valve-gears, springs, etc., and no adjustments are required. The outlet valves are of the simple poppet type.

The air upon leaving the low-pressure cylinder passes through an inter-cooler of the usual surface condenser construction, from whence it passes through a trap in which the moisture which has condensed in the inter-cooler and hangs in the air in the form of a vapor, is caught on baffles and drained into a small tank placed on the foundation.

The amount of moisture drained from the air by this device will depend on the percentage of saturation of the air before entering the compressor and the temperature at which it leaves the inter-cooler.

It has been demonstrated that the capacity of air to absorb moisture increases directly with the volume, regardless of pressure, and that it practically doubles with every 250 deg. F. increase in temperature.

To take for illustration an actual case, in order to show the efficiency of the device, a two-stage compressor designed for 90-lb. terminal pressure at sea level will carry about 27 lb. gage, or nearly three atmospheres ab-

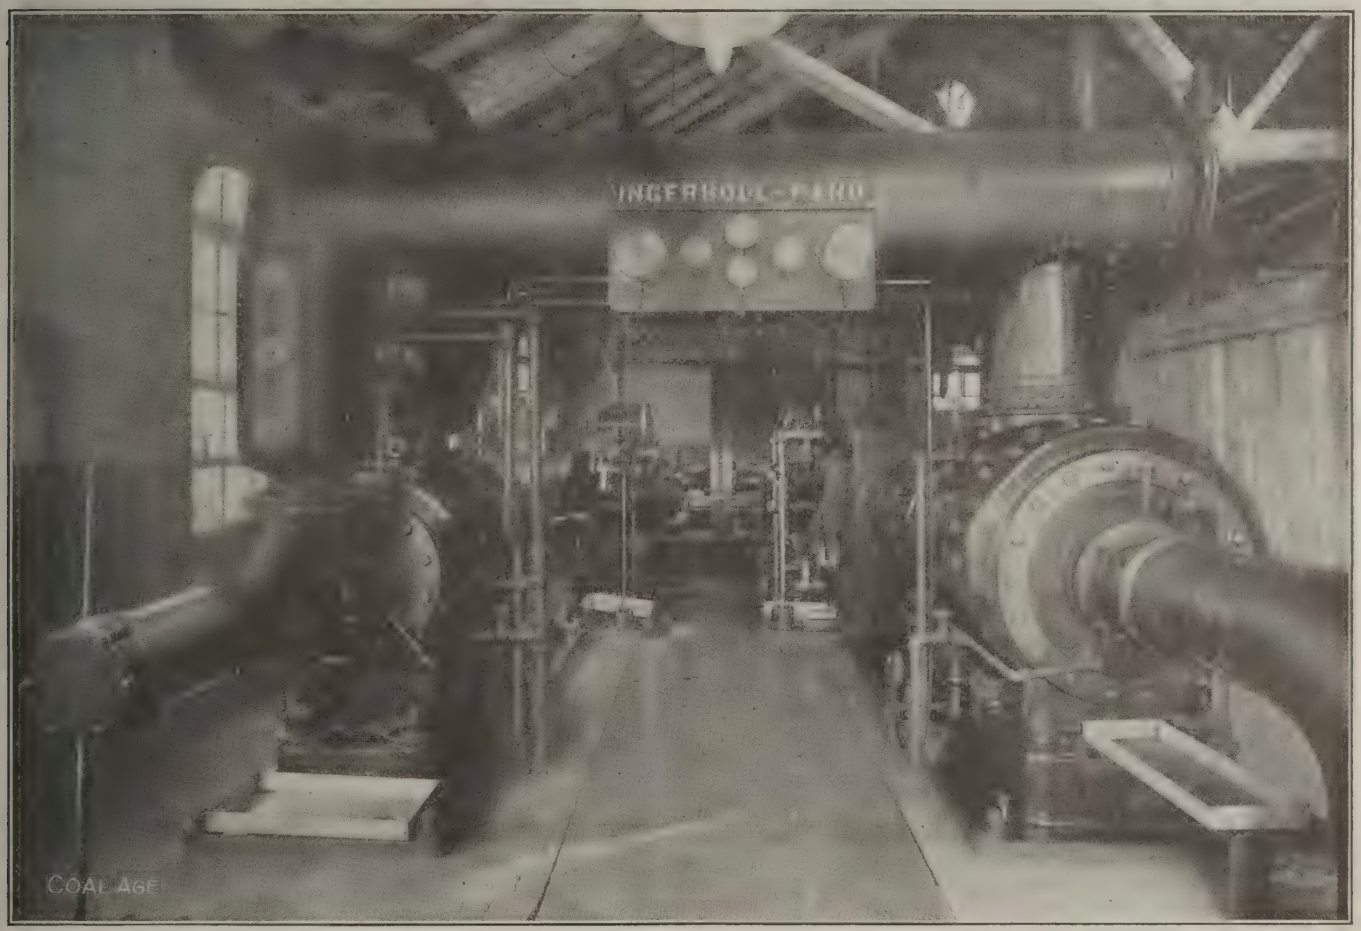

Fig. 2. A Compressor at the Plant of the Kingston Coal Co., at Kingston, Penn.

solute in the inter-cooler. This will give a temperature of about 240 deg. F. on leaving the low-pressure cylinder, if the intake temperature were 60 deg.

Assuming that the air on entering the compressor is in a saturated condition, the fact that its volume has been reduced by compression to nearly $\frac{1}{3}$ would mean that nearly $66\frac{2}{3}$ per cent. of this moisture would be precipitated, provided the temperature be reduced in the inter-cooler to 60 deg.

This is wherein lies the usefulness of the inter-cooler. But although this amount of moisture is given up by the air, it is not all precipitated, but the greater part hangs in the air in the form of a mist, and in the average installation is carried over into the high-pressure cylinder, where it is again taken up by the air, owing to the heat of compression, thus causing a loss of power, be-

sides trouble in the pipe line and at the points where the air is used. With the form of trap just described, nearly all of this moisture is caught and drained off.

Of course, the ideal conditions would be to extract all of this moisture before the air enters the compressor. This, however, would be impossible without a refrigerating plant. Much can be done, however, by taking the air from the coolest point possible, not from the inside of the engine room, or by installing some form of pre-cooler, which might be so designed as to clean the air as well as lower its temperature.

A Unique Air Cleaner Is Employed

A unique form of air cleaner is placed on the inlet to this machine. This is constructed of concrete and consists of a pit or box a little below the level of the engine room. A cover is placed over this box provided with openings so screened as to exclude large particles of foreign matter. The bottom of this chamber is filled with a heavy oil, just above the surface of which is placed a horizontal pipe provided with a long slot on the under side with one end closed and the other connected with the compressor intake conduit.

The air in passing to the compressor suction impinges more or less on the oil in the basin, leaving behind much dust and grit which would otherwise be carried over into the machine to the detriment of the valves and pistons. The oil can be easily removed and renewed as found necessary.

The use of this cleaner is of great benefit to the proper working of the compressor, and credit is due to the Lehigh & Wilkes-Barre Co. therefor, the device having been constructed by their engineers. It is, of course, impossible to put down in figures the saving realized by such an apparatus, its operation being in the nature of a preventative rather than a cure. Some such cleaning device should, however, form a part of every uptodate compressor installation.

The air from this machine is used to operate underground hoisting engines during the day, and at night a single pump for unwatering the mine, which takes the full capacity of the compressor, is operated. The main pipe line is, at present, 4 in. in diameter, but is to be increased to 6 in. in diameter to take care of the increased capacity afforded by the second machine.

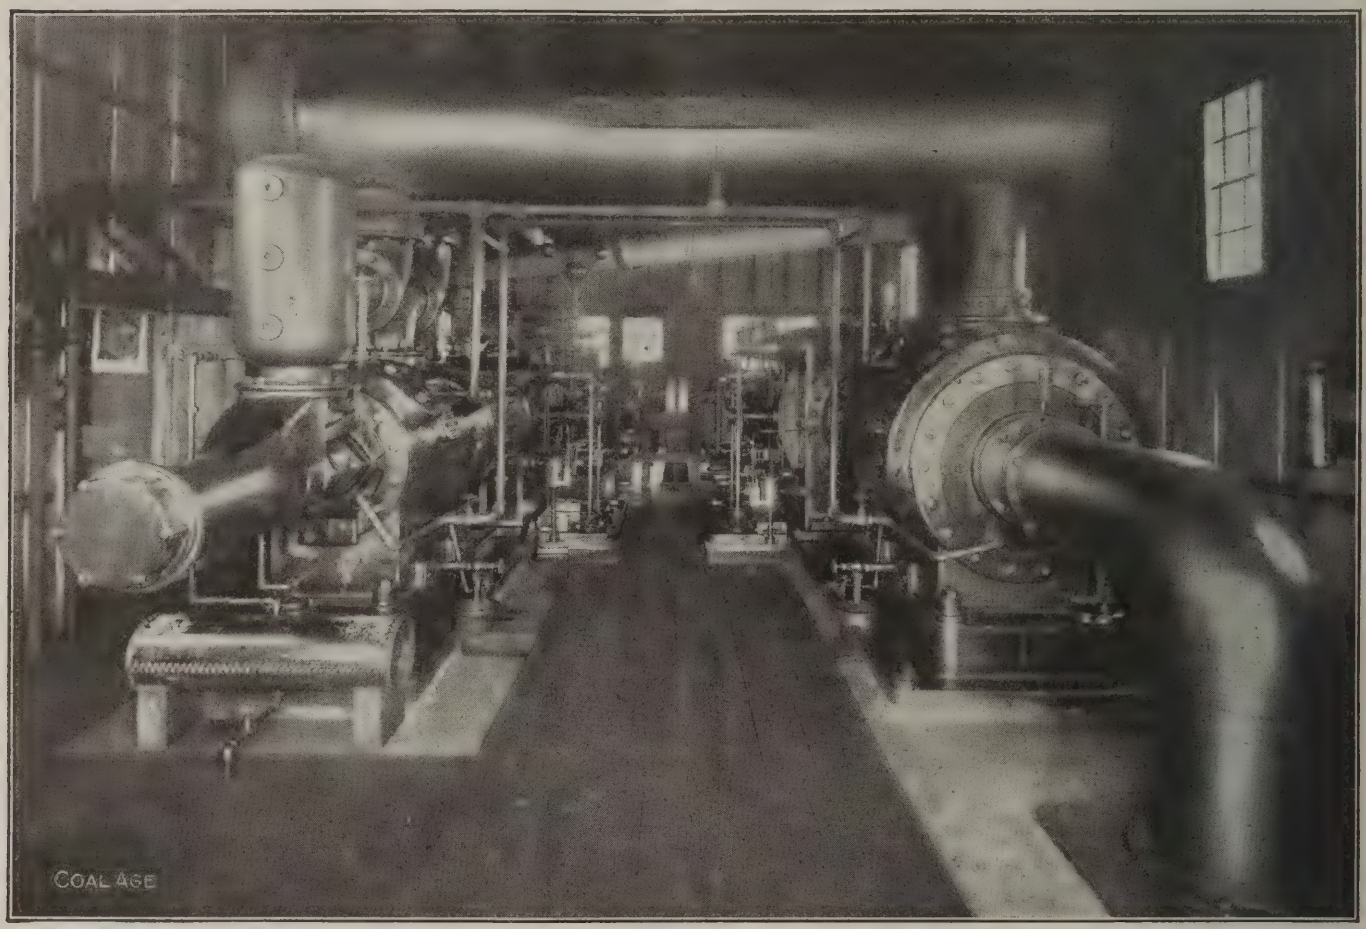

Fig. 3. Compressor Installed at the Dodson Mine of the Plymouth Coal Co., Plymouth, Penn.

But Little Steam Is Used

The engineer in charge made the assertion that his compressor used little if any more steam than the older machine of about one-half its capacity; and this in spite of the fact that the steam pressure fluctuates anywhere between 80 and 100 lb., so that the engine at times runs practically without cutoff.

A compressor of the same type but slightly smaller, was installed two years ago at the plant of the Kingston Coal Co., at Kingston, Penn., to take the place of two straight-line tandem-compound compressors with a combined capacity of 5000 cu.ft., which were installed some years before.

The new machine shown in Fig. 2 has a rated capacity of 3336 cu.ft. at 120 r.p.m., compressing to 100 lb. It easily takes care of this load, but owing to the increased

use of air in the mine, another compressor of the same type and design is to be installed.

A Battery of Receivers Is Employed

The air is piped to a battery of receivers, consisting of three 42-in. by 34-ft. cylindrical tanks coupled together. It is led in at the top to a pipe connection in the center of the battery. Provision is made for the new compressor when installed at the other end of the system.

This air-storage system was installed by the coal company to take care of the fluctuations of the load, and worked out well in practice. The air is used for pumps and hoisting engines underground.

This compressor is installed beneath a coal breaker, and consequently under unfavorable conditions, the intake being only protected by wire screens. In spite of this fact, however, it has not been necessary to renew any of

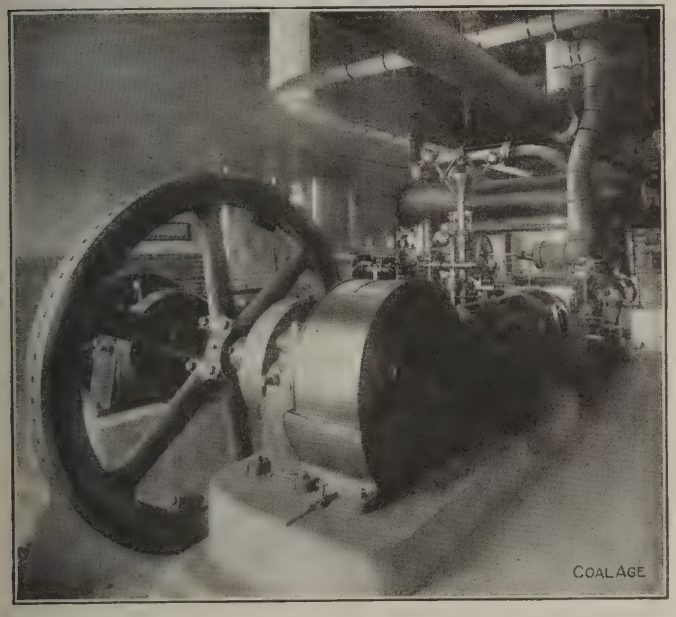

Fig. 4. Compressor at Gaylord Mine, Plymouth, Penn.

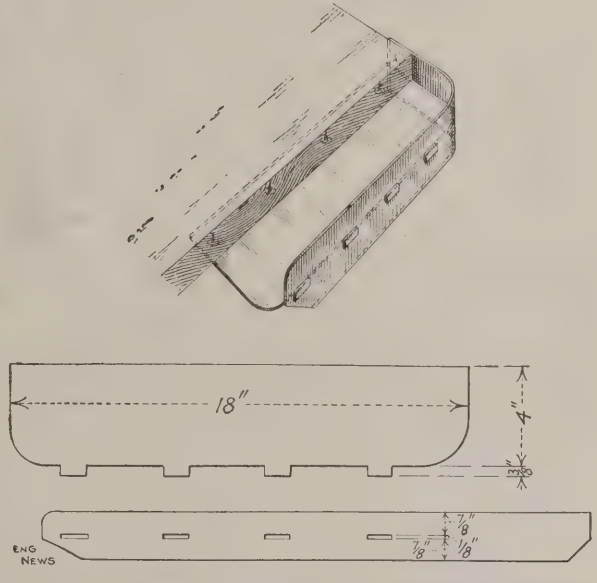
the air-inlet valves or valve springs since installation. The machine runs 24 hours per day, and has been speeded up to 125 r.p.m. for hours at a time.

At the Gaylord mine of the Kingston Coal Co., at Plymouth, Penn., another machine of the same type shown in Fig. 4 is installed for operating the mine hoist. This compressor has a capacity of 2000 cu.ft. at 134 r.p.m., and runs so smoothly that the writer was able to balance a nickel on edge on top of the main frame, while the machine was operating at 125 r.p.m. This compressor takes the place of an old Ingersoll-Seargent straight-line machine.



At the Plymouth Coal Co.'s Dodson mine, also in Plymouth, Penn., a compressor of the same size and type as that installed at the Kingston plant was put in to take the place of a 10-year-old duplex machine, a relic of former days. This compressor has run constantly for the last year and a half, generally being speeded up to about 125 r.p.m., at which speed it was possible for the writer to balance a nickel at the edge of the main frame, the same as was done at the Gaylord mine. This speaks much for the thorough manner in which the foundations were put in as well as the fine balancing of the machines themselves.

This compressor, about a year ago, was put to a rather unique use. Fire had broken out in the workings, and it was found to be impossible to get any fire-fighting apparatus within reach of the flames, owing to the noxious gases present. This difficulty was overcome by directing the full capacity of the compressing plant, which includes a small straight-line machine beside that above mentioned, into the workings and forcing the gases back until the fire-fighters were enabled to get near enough to extinguish the fire. This illustrates another use for compressed air in the coal mines, although it is one to which we hope it will be seldom necessary to resort.

In all of the above mentioned plants, the steam pressure fluctuates considerably. This does not, however, appear to interfere with the proper operation of the Corliss compressors, but makes it impossible to obtain any actual record of economy. The writer was unable, furthermore, on account of the briefness of his visit, to secure any data on the economical utilization of compressed air in the coal mines.

A Convenience for the Draftsman

Frank W. Miller, 422 Crane Ave., Detroit, Mich., has made a device illustrated herewith, which proves very useful to catch pencils, erasers, dividers, etc., which might otherwise be swept off the edge of the board and buried under the drawings below, in case the draftsman has

Cardboard Tray for Holding Drawing Utensils

much shifting of layouts and reference drawings from the top of his drawing board to his reference table at the side. The device consists of two pieces of heavy cardboard, cut as shown in the sketch. The tabs left on the piece forming the bottom fit into slots in the side piece, which is held quite firmly by mashing or spreading the projecting edges of the tabs. The bottom is tacked to the under side of the drawing board along the right-hand edge, while the side piece is bent around and fastened at the upper corner, as shown in the sketch. The whole thing is below the level of the board. During the last six months, Mr. Miller says, it has saved him many a search for buried instruments.—*Engineering News.*

The Pittsburgh Coal Bed

By W. G. Burroughs*

SYNOPSIS—A description of the Pittsburgh coal seam in all the four states in which it makes its appearance. The author, in drawing his statements from various official sources, enables us to get a good idea of the seam as a whole.

The Pittsburgh coal seam is the most valuable coal bed in North America. It was named by H. D. Rogers and his associates of the First Geological Survey, of Pennsylvania, in honor of the city of Pittsburgh, though it extends over parts of West Virginia, Ohio and Maryland, as well as Pennsylvania, in all of which states it is an important source of fuel. The workable coal area in the Pittsburgh seam is estimated by White at from 6000 to 7000 square miles. The bed has an average thickness of 7 ft. over an area of about 2100 square miles and it contains in all an estimated tonnage of 9,641,792,907 short tons.† It occurs at the base of the Monongahela formation of the Pennsylvania (Upper Carboniferous), series.

The Time Needed for Deposition of Coal Seam

The approximate length of time required for the accumulation of the vegetable matter from which the seam is composed, has been estimated by G. H. Ashley.‡ He states that 1 foot of peat can be laid down at the surface in 10 years. This will later shrink to 3 in., due to loss of moisture. It is estimated that it loses by partial decomposition about ¼ of the vegetable matter, but as its specific gravity increases to about twice what it was before compression, the original 3 in. will be compressed to about ½ of ¾ of 3 in., or 1⅛ in., and probably less in the deeper bogs. Thus, about one foot in a century is roughly the rate of accumulation of buried peat.

A cubic foot of peat from the lower part of the bed will weigh on an average about 50 lb. Due to loss of water this weight will be reduced ⅓, and the remainder will be decreased a further ⅓ by distillation, leaving, roughly, 25 lb. One cubic foot of coal from the Appalachian field will weigh on an average about 87½ lb. "Therefore, to make one foot of such coal will require 3½ ft. of well compressed peat.

Ashley writes that "the factor 3 has been selected as representing not the shrinkage of the whole bed, but the number of feet of well compacted, deeply buried old peat necessary to produce one foot of bituminous coal of the general character of the Pittsburgh coal of Pennsylvania. Applying this to our estimate that one foot of such peat requires a century for its deposition, 300 years is the time necessary to lay down one foot of bituminous coal. At this rate the Pittsburgh bed, where 7 ft. thick, required 2100 years for its accumulation, and 4000 years in its best development in the Georges Creek basin of Maryland."

Characteristics of Coal Bed

Over most of the large territory covered by the Pittsburgh bed, the coal has the following characteristic structure:* roof coal, over-clay or draw slate, breast coal, parting, bearing-in coal, parting, brick coal, parting, bottom coal.

"Roof Coal" and "Overclay"

The top bench of the seam is known as the "roof coal" and is made up of a number of thin layers, each 2 to 12 in. thick, separated from one another by shales, or clays, of varying thickness. Some of the layers of "roof coal" are clean, others contain much dirt and various other impurities.† In number, these thin coals range from one to eight, sometimes more, their total thickness seldom exceeding 3½ to 4 ft. The separating slates and clays sometimes are only half as thick as the coals, while in other places, they are often 2 or 3 times thicker than the coal.

The "overclay," or "drawslate," is an impure fireclay, varying in thickness and at times almost disappearing, and again in other regions, thickening up to 2 or even 5 ft. It is usually mottled and has many slickensides, rendering it dangerous, as large pieces of it will drop from the roof without warning. Therefore, it is generally taken down at once.

The "Breast Coal"

The "breast coal" is often, also, called the "main bench," and is usually the most important and valuable division of the whole Pittsburgh bed. In the Pittsburgh region, this section is generally about 3 ft. From this district it thickens gradually up the Monongahela, attaining a maximum of 6 ft. at Brownsville, while to the eastward in the Georges Creek and North Potomac basin, of Maryland and West Virginia, it increases in thickness still more, reaching 7½ and even 10 ft.

The top of the "breast coal" is nearly always of a boney nature for a thickness of 1 to 4 in. Frequently, this boney portion must be separated and rejected in mining; but even where this is not required, the top of the "breast coal" is distinctly harder than the rest, and inclined to show cannelly structure. As the Pittsburgh seam extends westward to the Ohio River, this "breast coal" member in certain districts thins to 2 ft. in thickness.

"Bearing-In Bench"

The "bearing-in coal" has been so named by the Monongahela River miner, because in mining operations, the undercutting of the "breast coal" is made in this layer, the latter being wedged or blown down, and the "brick" division subsequently taken up. The "bearing-in coal" is usually brilliant and pure. It varies in thickness from 3 to 6 in., and is inclosed by two thin parting slates, almost exactly alike in color and structure. In the region between Pittsburgh and Brownsville, these slates are ¼ to 1 in. thick, and of a dark mottled gray color.

In West Virginia, they are generally a dark bone, and will sometimes burn with the coal.‡ The persistency of

these twin slates over all the regions drained by the Monongahela, east to the Georges Creek and North Potomac field, and west to Wheeling, Bellaire and the neighboring regions of Ohio, is one of the remarkable features of this coal bed. When, however, the areas of this coal south of the Little Kanawha River in West Virginia and west from the Muskingum in Ohio, are examined, these twin slates are not found, or if represented, are no longer recognizable as the Monongahela partings; but the "roof coal" and the "overclay" appear to be present."

MAP OF THE HORIZON OF THE PITTSBURGH COAL BED IN PENNSYLVANIA, WEST VIRGINIA AND OHIO

The Maryland deposit is excluded. It will be noted in the illustration that in West Virginia there is a line which shows where the Pittsburgh bed becomes thin and of little commercial value. While some of the deposits west of that line in Ohio are of considerable value, many are utterly valueless, and some are mere traces. In other places, the bed is missing and its horizon alone can be determined. As this is a map covering the horizon of the coal bed and not its actual presence, the profitable coal area, especially in Ohio and West Virginia, will be considerably smaller than that shown.

The "Brick Coal"

The "brick coal" comes next beneath the lower of the twin slates. It owes its name to the fact that it comes out in oblong rectangular blocks, like common bricks. It is generally about one foot thick. The parting which separates the "brick coal" from the "bottom coal" is always present along the Monongahela from Brownsville to Pittsburgh; and it is also represented in the Georges Creek and North Potomac field, but in the Fairmont region it is rarely present, the bed in that section generally being undivided below the "bearing-in coal."

The "bottom coal" is from 12 to 20 in. thick along the Monongahela in Pennsylvania. It contains many thin, slaty, sulphurous laminae.

I. C. White gives the following section, taken near Scott Haven, Penn., as typical of the Pittsburgh bed, as it occurs over large areas:

THE PITTSBURGH BED AT SCOTT HAVEN, PENN.

		In.	
"Roof"	Coal, several films of earth	3¼	46¼ in.
	Shale, black, earthy	2	
	Coal	2¾	
	Shale gray, streaks of coal near top	11	
	Bone, a hard, dull, impure, coaly layer	1	
	Coal	2½	
	Shale, black	0¼	
	Coal	1¾	
	Shale, black, coaly	1	
	Coal	3	
	Shale gray, with irregular coal streaks	4½	
	Coal, compact, free from "binders"	9¼	
	Slate, with coal streaks	1½	
	Coal	2½	
"Overclay," impure, fireclay, light gray above, getting browner and then a much darker gray with coal streaks of irregular shapes, especially toward the base			10½ in.
"Breast coal" (with 1½ in. of bone at top, and next 10 in. harder than the rest of the bench)		41½	7⅝2 in.
Shale, dark, grayish brown, mottled		0¼	
"Bearing-in coal," clear and brilliant		4	
Shale, dark, grayish brown, mottled		0½	
"Brick coal," clear and brilliant		11	
Shale parting		0⅛	
"Bottom coal"	Coal with few thin dirt layers	12½	
	Shale	0¼	
	Coal, bright and clean	2	
Total thickness of Pittsburgh bed			10 ft. 9⅜ in.

In Athens and Gallia Counties, Ohio, a marked change occurs in the Pittsburgh bed. The well known structure of the seam, described above, is wanting. In its stead, we find a threefold division. This consists of an "upper bench," and a "lower bench" of coal separated by a layer of clay or shale. Usually the "Lower bench" is the more important, and in places it is the only one mined; but it is not always the most important, as is shown in the following section.

PITTSBURGH COAL SECTION AT SHARPSBURG, ATHENS COUNTY, OHIO

		Ft.	In.
Shale, unmeasured			
Upper bench	Coal	4	0
	Bone coal	0	2
	Coal	0	4
Clay parting		1	0
Lower bench	Coal	2	10
	Pyrites parting	0	0½
	Coal	0	8

SECTION OF THE SAME SEAM AT BLADEN, GALLIA COUNTY, OHIO, ON THE BANK OF THE OHIO RIVER

	Ft.	In.
Shale	2	0
Upper bench coal	0	4½
Clay	1	0
Lower bench coal	2	9

Ohio Geological Survey Bulletin 9.

Usually, the structure is more complex than is shown in this section.

The structure of the Pittsburgh coal in Ohio presents two distinct phases, as follows: In the eastern counties it is usually normal and similar to that of the great fields east of the Ohio River; farther southwest in Ohio, as has been stated above, the structure is different, but it is persistent in that territory. Between these two modes of structure are intermediate, transitional forms, as the Ohio Geological Survey points out.

The Pittsburgh coal is also remarkable for the number and size of its "clay veins," which penetrate the bed in every region, whether along the Monongahela, or the Great Kanawha, 200 miles distant. In some districts, these "clay veins" are more frequent than in other regions, but they occur in all. I. C. White regards them in most cases as being due to earth movements which squeezed up the underclay into and often through the over-lying coal.

An analysis of the Pittsburgh coal from a mine in Belmont County, Ohio, which county has a larger quantity of that coal than any other county in that state, is here given, taken from the reports of the Ohio Geological Survey.

ANALYSIS OF PITTSBURGH COAL FROM BELMONT COUNTY, OHIO

Ultimate		Proximate	
Carbon	71.45	Moisture	3.39 (a)
Hydrogen	5.21	Volatile matter	36.84
Oxygen	11.27	Fixed carbon	51.91
Nitrogen	1.24	Ash	7.86
Sulphur	2.97		100.00
Ash	7.86	(a) = moisture in air-dried sample about 3%.	
	100.00		
Calorific value	7217 calories.		

Prof. N. W. Lord, of the U. S. Geological Survey, found the average calorific value of samples of Pittsburgh coal from Pennsylvania to be 13,557 B.t.u.

Pittsburgh coal is a leading fuel for the production of illuminating gas. For the manufacture of coke, Pittsburgh coal stands second to none. The average of a large number of analyses of Pittsburgh coal and coke of the Connellsville basin, is here given:

CONNELLSVILLE COAL AND COKE

	Coal	Coke
Moisture	.....	0.184
Volatile matter	31.04	0.552
Fixed carbon	61.97	88.726
Ash	5.77	9.993
Sulphur	1.22	0.533
Phosphorus	.....	0.010

22nd. Annual Rept., U. S. G. S., p. 176.

Reporting on Coal Properties

By Frank Haas*

SYNOPSIS—A report should tell the person who is to receive it all that he needs to know and no more. A busy man won't read a long disquisition even about his own property, and may be unwilling to hunt up all the abstruse terms the engineer may choose to use. Every report should be attractive and facts should be mainly conveyed by maps, diagrams and photographs rather than in the most graphic of language.

Probably every engineer at some time in his career will have to make a report on a coal property. The work well done will bring quicker and larger reward than any other, and every mining engineer should study this feature of his profession. Experience, it is true, is the best help to that kind of work, but there is a way of profiting by other people's efforts which will go a long way toward replacing such deficiency.

What the Report Is to Be Used For

The engineer should have a clear understanding of the object of the report so that he will not waste his time and the time of those who read it by introducing needless detail. It is necessary to know if the property in question is to be purchased or sold, whether it is to be exchanged for other lands, whether it is to be considered as an immediate operating property or whether it is to be taken by bankers as a basis for a bond issue.

*Consulting engineer, Consolidation Coal Co., Fairmont, W. Va.

Note—Article prepared to be read at the meeting of the West Virginia Coal Mining Institute, Charleston, W. Va., Dec. 8-10, 1913.

A Report to a Banker

A report made to a banker should be different from one made to a president or general manager, who perhaps may contemplate immediate operation. The bankers want to know whether the property will earn interest on the bonds which they are floating or which have already been issued and whether it will earn a sinking fund for retiring the bonds and a margin large enough to make investment amply safe.

If your information and judgment warrant it, the quickest and shortest way of convincing the banker will be most acceptable to him. Give the banker no details which he does not understand. Ordinarily, he knows nothing of anticlines and synclines or butts and faces, and so on. The chances are that if he does not understand, he will not admit it. Anything in a report which is not plain or is not understood is a weakness. It does not matter whether it is your fault or not, the damage is done and the world and modern business does not stop to rectify personal grievances. However, by all means do not underestimate the banker in his knowledge of the coal business or you will regret the day, for some time you will meet a wise one who will ask questions which are interesting and would be decidedly embarassing if you did not fortify yourself with a supplementary report of detail facts.

Reports to Managers

If, on the other hand, you make a report to your president or general manager, the proposition is one of an entirely different nature. Perhaps as you should have previously determined, you are only to accumulate the facts, and if so, devote yourself to this alone; your opinion will probably be asked for some time, so it isn't necessary to intrude it until the proper occasion. This kind of a report is the most difficult of all to make.

To place all the facts of a proposition in such a manner and so concisely and plainly to a second party that he can form a definite opinion without further question or investigation, is a success indeed. Probably you may have to know your man as well as your property and in such a case it is well to put yourself in the other man's place and see if you can, in a theoretical way, formulate an opinion from the facts in hand. If you are sincere and conscientious in the criticism of your own work, and find it satisfactory, the probabilities are that your effort is a success.

Care in Ascertaining Facts

A common error is lack of discrimination between facts and opinion. There is nothing that will so completely destroy an otherwise good report as an inadvertent statement which is offered as a fact that cannot be fully substantiated. I have seen reports in which there was apparently no thought or idea of discrimination. A report recently passed through my hands covering, in a general way, several hundred thousand acres in eastern Kentucky from information apparently gathered in two weeks' time.

In this report nine seams of coal were identified and the correlation carried without a hitch or a question for over one hundred miles. It was a decidedly remarkable achievement if it were true, yet the report gave no indication other than that its statements were proven facts. Yet the man, I feel sure, was sincere in his own mind, but did not realize the mischief he was making for others following in his path.

I have in mind now a property on which twelve separate reports have been made and the opinions formed after a careful study of them would vary widely; in fact, the property would hardly be recognized except for the geographical names. The character of coal was variously described in the several reports as if it varied from semi-anthracite to coking coal, all this occurring without any desire on anyone's part to willfully deceive, but from a lack of discrimination between fact and opinion, or gross ignorance, for the facts in this case were so very apparent and so readily available.

Considerable time and labor are consumed in weeding out such inaccuracies. A statement once made must be either substantiated or proven wrong and nothing must be left for interpretation, for this is the real object of the report. It is far easier to go into a virgin field and cover the proposition concisely and briefly than to make a report when the territory has previously been described in an inaccurate manner.

Prejudiced Opinion

Another very important matter to be considered is that of prejudice. The coal fields of the Appalachian system are fairly well known and those who have followed the profession are more or less familiar with the entire system and, by hearsay, publications or otherwise, have ideas in regard to the various fields and in some cases even positive opinions.

It is a difficult thing to pull away from such ideas or opinions and constant vigilance is needed to keep these preconceived ideas from entering into our estimates, but it is essential that they should be excluded. It would be a clever writer, indeed, who could incorporate a prejudice and not have it discovered. But this failing is common and most reports are contaminated in this way.

A prejudice may be in the right direction, but if it is discovered it will naturally throw the reader in an opposite direction and the injury will be threefold, first to the reader of the report, second to the property and finally to the writer himself. And it is usually a hopeless case, for once it is known that a person is prejudiced, argument is considered useless and generally not offered.

Of course, there are many reasons why these prejudices occur and many excuses for their existence. For instance, one may be called upon to report on a property belonging to one corporation and subsequently required to do the same on an adjoining property, which may belong to a competitive company, and it is almost against human nature to think that the statements of one's first report would not affect those of the second.

Find Out What Facts Are Needed

It has been said heretofore: "Know your man." This adage may be used here to express that we should understand just what he wants to know. He is paying his money for a record of facts and perhaps an opinion on a piece of property and it is your duty to furnish him with the information that he wants and in the way he wants it. It is sometimes surprising to hear some of the questions that are asked, simple but entirely to the point, which would not have occurred to the engineer had the suggestion not been put.

It becomes almost a habit among those in the same profession not to discuss or even mention things which are to such profession self-evident facts, but which may

be to others unheard of and unknown. It is only a short time ago that I had occasion to travel over a considerable territory with an owner of a large property. The man was serious and thoroughly interested—he had his money invested and wanted to know in a manner that he could understand just how much coal he had, what kind of coal it was and what kind of market the coal would suit and where that market was, and so on.

Those who have been through the mill can appreciate how tedious it becomes to answer the fire of questions that can be put in a week's trip. But after all, it might almost be said that he who answers or tries to answer those questions learns as much as the man who asks them, in that it gives ideas as to what people who are not acquainted with the coal business want to know and what facts should be covered in a report.

A Brief Report with Extensive Examination

I have in mind now another man for whom I have made numerous reports. At first these reports were patiently read through; after a while I found that the last page was read first and the fore part afterward, so adjusting the reports to the conditions, the last page was submitted first. This proving satisfactory for a time, I found that the rest of the report was only indifferently read and more probably not read at all; so finally, to perfect the matter still more, the rest of the report was omitted, which apparently was most satisfactory of all. It is a fact that the largest acreage, or deal, that went under my observation was based on a report that had less than two typewritten pages. But don't assume that the work wasn't done; the supplementary report, though not submitted, was quite complete and handy should a critical moment have arrived.

Maps Should Be Reduced to Manageable Size

Having pointed out that a report should be brief, concise and without prejudice, it might also be added that it should be attractive and pleasing in its arrangement. Anything that can be illustrated by a map or a diagram should be so presented, not only for brevity, but for quick understanding. A map is far more comprehensive than any description could be, diagrams of sections are more easily read and a few photographs of characteristic features add greatly to the value and attractiveness of a report.

For the purposes of a report, a map is merely an illustration, and such a scale should be selected that the entire proposition can be grouped at a glance; by all means avoid a map which requires a special table to display it; it should be rather one that a person can hold in two hands and comfortably see it all. Avoid unnecessary detail, but bring out the essential features prominently; should some detail require a larger scale, provide another map, which is a section of the whole, large enough to demonstrate it properly, but maintain a uniform size of map if possible. The facilities for enlarging or reducing maps are or should be available in any engineer's office, and there should be no excuse for maps not being reproduced in the most attractive and convenient form.

Whatever the illustrations you may see fit to offer, by all means, make them neat in appearance. Any man who makes any pretense of being an engineer must be a draftsman, and there is nothing that will provoke criticism so readily as a careless or untidy map.

However, whatever the subject, whatever the object, make your report in such a manner that you will have no excuses to make, and the presentation will meet all your own conscientious criticisms. Then the probabilities are that your effort will be a success.

Pulverized Coal

James Lord, president of the American Iron and Steel Mfg. Co., Lebanon, Penn., addressing the Engineers' Society of Western Pennsylvania, gave the following specifications for powdered coal for metallurgical uses: (1) The free and combined moisture must be expelled by artificial heat till their combined percentage falls to 0.5 per cent. (2) The coal must be pulverized so that 95 per cent. will pass through a sieve of 100 meshes to the square inch. Over 80 per cent. at the Lebanon works will go through a 200-mesh sieve. (3) The coal should have a high volatile content, not less than 30 per cent. (4) The sulphur should not exceed one per cent.

The cost of drying, pulverizing and transmitting the dust amounts to 50c. per ton of which the first two items cost a total of 40c. When pulverized coal in the furnaces is used, smoke is eliminated. Sometimes the coal catches fire in the storage bin, in which case the supply is stopped and the burning coal is fed to the furnace. There is no danger of an explosion under these conditions, in fact no explosions have been experienced at the Lebanon works.

William A. Evans, New England manager, Griscom-Russell Co., Boston, Mass., discussing the paper, stated that drying was not absolutely essential but effected a large economy. The dryer can only be eliminated where the pulverizers will permit moist coal to pass through them. If screens are used for the separation of the coal and fine material, they clog up immediately when fed with moist coal. Moreover, damp powder in the storage bin will coke almost solid and develop heat tending toward spontaneous combustion.

Pulverized Slack Costs as Much as Mine-Run Coal

Coal cannot be taken from the cars, and be pulverized and delivered to the furnace for much less than 50c., certainly not for 10 or 12c., as has been stated. The cost of slack pulverized is about the same as that of mine-run which would be used on grate fires. Low-grade coal is no better suited to this class of furnace than to ordinary purposes. Much slag is deposited in the furnace by such coal and the furnace front has to be repeatedly opened to permit removal of the slag; thus the furnace is cooled, heat is lost and castings are ruined.

The entire combustion space should be free from any metallic surface. The failure to take this precaution is probably the reason why success has not been obtained in burning pulverized coal under boilers. Coal dust cannot be burned in brick checker-work because of its slagging qualities. In this department, therefore, it cannot compete with producer gas but in its proper field, the use of pulverized coal is 25 per cent. cheaper than the indirect process of turning coal to gas and burning the gas in a furnace. Coal is also about 60 per cent. cheaper than oil for furnace use.

Note—Pulverized Coal in Metallurgical Furnaces, Vol. 29, p. 362, October, 1913.

Burning Impure Coal

H. R. Barnhurst, engineer of the Fuller Engineering Co., Allentown, Penn., stated that by the use of special furnaces pulverized anthracite containing 25 per cent. ash could be burned, also coke breeze with 15 per cent. ash and even washery waste with 52 per cent. ash. He also stated that 4 B.t.u. can be saved per degree of preheating per pound of fuel when 50 per cent. excess air is admitted. In his belief the pulverization should produce a dust of which not less than 85 per cent. should pass the 200-mesh screens and not less than 95 per cent. the 100-mesh.

One pound of coal will evaporate 6 lb. of moisture in the fuel. One man can deliver the coal to a drier of 6 or 8 tons hourly capacity. One man can operate mills capable of grinding the same amount of coal and delivering it finished in the bins. The repairs of dryer and mills will be less than 2c. per ton. The power including conveying and elevating will be about 17 hp. per ton of product per hour.

Large economies have been made over raw-coal firing and the use of coal in producers: In continuous furnaces for heating billets, 24 per cent; in openhearth producer-gas fired furnaces, 30 to 35 per cent; in puddling furnaces, 33 to 50 per cent.; in heating and busheling furnaces, 20 to 25 per cent.

I. W. Rawlins declared that coal with 2.05 per cent. sulphur had been used at Cananea and E. D. Barry instanced the use of West Virginia slack coal with 2.71 per cent. of sulphur, Pittsburgh coal with 1.28 per cent. and Illinois coal with 1.47 per cent.

Safety First Signs

A great many coal-mining companies are placing illuminated signs in their underground workings, with the idea of preventing accidents and thereby saving lives. As constructed today by the Electric Service Supplies Co., of Philadelphia, these signs are practically indestructible and necessitate but little cost for maintenance.

Mining companies can place such danger signs at any point where human life is in danger by exposed electric wires, switches, third rail, etc.

These Danger Signs Are Practically Indestructible

The Roller-Curtain Sign Shown on Left above Is a New and Novel Type. The Curtain Contains a Number of "Safety Precepts"

The very latest development in the construction of safety-first signs is the Keystone illuminated roller-curtain sign, shown in the accompanying illustration. This particular type is an educational feature with great possibilities. The curtain may contain any number of "safety precepts" covering an entire campaign, and conforms nicely in its adaptability to the modern safety idea.

In a suit in Alabama it was contended that a man working about an air pump was asphyxiated by the air discharged. It was said that an explosion of the lubricating oil in the compressed-air pipes and receiver filled the pump cylinders with noxious gases and caused the man's death.

An Analysis of the Commerce Law

By Sydney A. Hale*

SYNOPSIS—There are probably few shippers who have little more than a mere superficial knowledge of the "Act to Regulate Commerce." In order to make the measure effective in all its ramifications, it was necessary to embody many unusual provisions. Thus the railroads are not the only ones who may be culpable of infringement of the law and the incautious shipper would do well to post himself on its intricacies.

The prosperity of the United States, as of no other country, is dependent upon its transportation facilities. Business moves and has its being in this interlacement of steel, approximating a quarter of a million miles. Unless these avenues are kept open, community isolation and industrial disintegration would be inevitable—and swift.

With this power of financial life and death concentrated in the control of one agency, it was only natural that arrogance should creep in and the railways, for a time, forgot that, while in their strength they might crush, they would be buried eventually under the commercial havoc they wrought.

Individual states were the first to take up the issue with statutory curtailment of the railroads' license, but local regulation proved inadequate. The national government, acting under the powers of the commerce clause of the Constitution, then stepped in. With the Constitutional grant that Congress shall have power "to regulate commerce with foreign nations and among the several states" as their authority, senators and representatives proceeded to make transportation amenable to the public will. The Cullom Act of 1887 was the result. But this soon proved more admonitory than corrective. Amendments were grafted on it in 1889, 1891 and 1895. Still complaints grew apace. In 1906, the act was vitalized by the so called Hepburn amendments and regulation that regulated came into existence.

The Objects of the Act

Primarily, the act is an instrument to regulate the transportation agencies of the country, but, inasmuch as these agencies exist by the traffic the public tenders them, by implication in every instance, and by direct phraseology in several, the shipper is also subject to the provisions of the law. Thus, where the act strikes down an unjust discrimination of the carrier, preferential to some favored industry, it also strikes at the beneficiary of such discrimination. More than that, in the duties and burdens it places upon the shipper in his relations to the carriers and the public at large, equally, if not more so than in the demand it makes of the carriers, the vitalizing features of the act as it stands today find their fullest expression.

An intelligent understanding of the law must comprehend a full knowledge of its dual requirements. Preliminary to this must be cognizance of what the act controls. By specific description, the term "common carrier" is made to embrace not only the railroad proper, or the rail and water lines when land and water facilities are used under a common arrangement for continuous carriage, but pipe lines, express and sleeping-car companies.

Every commodity, excepting water and natural or artificial gas carried through pipe lines, comes under its restrictions. "Railroad" is made inclusive of all bridges and ferries used in connection with any railroad, all the road used by any corporation operating a railroad, all switches, spurs, tracks, terminal facilities, depots, yards and grounds used or necessary in the interstate transportation or delivery of persons or property. "Transportation" itself covers cars and other vehicles and all instrumentalities and facilities of shipment or carriage, irrespective of ownership, and all services in connection with the receipt, delivery, elevation and transfer in transit, ventilation, refrigeration, icing, storage and handling of property transported.

Discussion of the commerce act has been all so largely with respect to the duties it lays upon the carrier that a brief recital of what the shipper is entitled to under the law from these agencies of transportation is deemed sufficient here. In the first place, he is entitled to transportation upon reasonable request therefor. The carrier is also bound by law to give him through routes and joint rates applicable thereto. All charges must be just and reasonable.

The classifications of freight and the rules and regulations governing rates, classifications and tariffs, must be able to meet the same test. The shipper has a right to rates that are not only just and reasonable in and of themselves for the services rendered, but transportation charges that shall not discriminate against any particular traffic, persons or communities where the conditions and circumstances are substantially similar and the service is of a like and contemporaneous kind. The foregoing in itself is an inhibition against preferential rates to traffic, persons or localities, but the act also carries the specific prohibition against preferences in rates and practices.

All Rates Must Be Made Public

The Act to Regulate Commerce also makes it unlawful to charge more for a shorter than for a longer haul over the same line or route in the same direction. Where a railroad reduces rates to meet water competition, the elimination of that water competition will not be permitted to furnish justification for again raising the railroads' rates. These provisions were storm centers in the legislation of 1910. Upon application by the carriers, existing adjustments in violation of the long- and short-haul principle must be withheld until such time as the commission might pass upon the commercial justification of such departures.

One of the greatest aids to the shipper and most effective deterrents of discrimination is found in the provision of the law which requires carriers to post all changes in rates at the stations to and from which they apply not less than 30 days in advance of their effective dates. From these tariff charges no deviation is permitted, either directly, or by devices such as false billing, false classification or false weight.

Practices of such devices subject the carrier and its agents to a fine of not more than $5000, or two years'

*5455 University Ave, Chicago, Ill.

imprisonment, or both; the penalty for rate discrimination is a fine not exceeding $5000, or imprisonment not exceeding five years, or both. Carriers are forbidden to engage in traffic without tariff authority. The shipper may demand written rate quotations from the carrier and damages arising from a misquotation or failure to quote within a reasonable time carries a penalty of $250, accruable to the United States.

The shipper is entitled to through routes for his consignments. Where several routes are available under a joint tariff, he is also given the right to direct the routing of his goods, both intermediate and terminal, subject to such reasonable exceptions as the Interstate Commerce Commission may from time to time prescribe. The carrier must also provide reasonable facilities for operating through routes and prescribe reasonable rules and regulations governing the operation of said routes.

It must furnish switch connections with private sidetracks, where such connections are reasonably practicable, can be put in with safety and the volume of traffic warrants the construction and maintenance of such connection. Cars must be distributed among shippers to the best of the carrier's abilities and without discrimination. Provision must likewise be made for the interchange of traffic between carriers and discrimination between connections is forbidden, though one railroad is not compelled to give the use of its tracks and terminal facilities to a competing line. The railroads are not permitted to adopt devices to defeat the continuous carriage of through freight.

Action for Recovery

The act also provides that the shipper may look to the initial line for reimbursement for loss or damage to freight; this is the Carmack amendment. With the exception of timber and the manufactured products thereof, and supplies for the carrier's own use, no railroad may transport any commodity in which it has an interest, direct or indirect. Free transportation, as far as the shipper is concerned, is limited to the necessary caretakers of live stock, poultry, fruit and milk. The carrier may not disclose any knowledge of a shipper's business except to governmental authorities, connections or in the course of legal process. A shipper is entitled to reasonable compensation for services or instrumentalities furnished in connection with transportation.

If the carrier is derelict in any of the obligations laid upon it by the act, the law gives the shipper the right to make complaint to the Interstate Commerce Commission, in whom is vested plenary powers to hear such complaint, determine the merits thereof and make appropriate orders in connection therewith. That there should be no defeat of justice through narrow construction, the law confers this right of appeal to the commerce board on "any person, firm, corporation, company or association, or any mercantile, agricultural or manufacturing society, or other organization, or any body politic or municipal organization or any common carrier." The commission is also authorized to entertain complaints forwarded by state railroad commissions. "No complaint," reads the law, "shall at any time be dismissed because of the absence of direct damage to the complainant."

This right of complaint embraces not only rates and practices in effect at the time of filing of the petition, but also changes about to be put into effect. The commission can, if it deems the equities of the case warrant the action, suspend any proposed advance for a period not exceeding ten months. As to all charges advanced since Jan. 1, 1910, the burden of proof to defend such increase is upon the carrier.

If the violation of the act has resulted in damage to the complainant, the commission has discretionary powers to award the injured party reparation. In any award of reparation, it may be parenthetically remarked, the commission makes a practice of reaching the man who paid the freight. All complaints for the recovery of damages must be filed within two years from the time the cause of action accrues.

Precautions that Assure Effectiveness

Since the underlying purpose of the act is to secure equality of opportunity, it necessarily follows that all favoritism which operates to destroy that equality is unlawful; that it is as reprehensible for the shipper to be the recipient of unlawful gratuities as it is for the carrier to permit preferential adjustments to exist. To obtain the needed reciprocating action of the law, Congress hit upon publicity, coupled with corrective powers, as the instrument of accomplishment. It said: Require every rate, every practice of the common carrier to stand open before the whole world. Publicity of rates and regulations will expose the discriminations against which popular clamor has been directed; we clothe the Interstate Commerce Commission with full powers to take summary action in correcting the evils that show themselves.

But publicity without effective enforcement would only aggravate. To avoid this, the published rate was made supreme and on the shipper is laid the burden of knowing what this published rate is. He must know and he must pay this rate, no more, no less. This is the great responsibility the law puts upon the shipper, knowledge of the published rate and absolute adherence thereto. If a railroad misbills, that does not avoid the shipper's liability to pay the legal rate. Even the practice of offsetting overcharges with undercharges is frowned upon. Each shipment is considered a separate transaction and carriers are required to exhaust their legal remedies in collecting their full tariff rates. Unlimited extension of credit by carrier to shipper has, in at least one instance, been urged as a basis for indictment on the grounds of rebating.

Harsh as this principle may seem in theory, onerous as it sometimes proves in practice, it has been recognized generally as the only way in which the equality sought for in the law might be enforced. One deviation from the published rate would open the door to more. Misquotation of rates subjects the carrier to fines recoverable by the United States, but offers no redress to the injured shipper.

Some Unusual Features of the Act

This in no way contravenes the shipper's right to just, nondiscriminatory rates and charges, for every unreasonable rate or practice is declared unlawful. To properly understand the situation, one must know the distinction between "legal" and "lawful;" the publication of a rate in the manner prescribed by law, runs the substance of a principle announced by the Interstate Commerce Commission in the case of the Arkansas Fuel Co. vs. Chicago, Milwaukee & St. Paul Railway Co., 16 I. C. C. Rep., 95,

makes the rate a legal rate, but the mere publication cannot make a rate lawful that is unreasonable and excessive; no rate can be lawful in the sense of being immune from attack, either with respect to past or future shipments, if it be excessive and unreasonable in amount.

So, if the legal rate be unlawful, the only course open for the shipper is to pay it and then seek relief from the commission. Granted that the rate is unlawful, the commission will then fix a just rate which shall be open to every shipper alike and order reparation—if the claim is well founded therefor—to the injured shipper. And that full justice may be preserved, the principle of reparation will apply to all who have shipped under the rates condemned, when such shipments are not barred by the statute of limitations and when they come within the provisions laid down by the commission in its original rate and reparation decision.

Congress was not content to rest with the general declaration that all rates, charges, practices and regulations should be just, reasonable, nondiscriminatory and nonpreferential, but augmented the general prohibition against charges opposed to these principles by singling out special vices for condemnation in the case of the shippers; it has also not stopped with the pronouncement that they must pay the published rate without deviation, but has stamped illegal certain devices that had been used to defeat the spirit of the law. Connivance or collusion of the carrier or its agents offers no mitigation. The attempt to defeat the rates is made equally criminal with the actual accomplishment of the unlawful project; both are declared frauds and misdemeanors and made punishable by a fine not exceeding $5000 or, in the case of real persons, imprisonment for a term not exceeding two years, or both.

Liability of the Shippers

But the law goes still further in its check on the unscrupulous. It makes the unfounded claim also a fraud and a misdemeanor, punishable by the same penalties and extending in the same way to shippers and their agents found mulcting the common carrier by this same device. That evasion of the intent of this section of the act may not be easy, the prohibition runs against those who, "by false statement or representation as to cost, value, nature, or extent of injury, or by the use of any false bill, bill of lading, etc., knowing the same to be fictitious or fraudulent, attempt to obtain any allowance for damage in connection with the transportation of property, whether with the connivance of the carrier, whereby the compensation of such carrier is made less than the regular rates.

When a preferential adjustment is made, railroad officials not infrequently set up the defense that the rate or practice complained of was not the voluntary act of the carrier, but was forced upon it by the pressure of large shipping interests controlling tonnage of such volume that the transportation company was loathe to see it go to other lines. In its attempts to safeguard equality of opportunity, Congress has taken cognizance of this condition; it has declared that any shipper or his agent who, "by payment of money, attempts to induce any common carrier or its officers or agents, to discriminate unjustly in his favor, as against any other consignor or consignee," shall be guilty of a misdemeanor and liable to a fine of $5000, or two years' imprisonment, or both, for each offense. In addition, such shipper or its agents, shall, together with the common carrier, be liable jointly or severally for all damages arising from such discrimination.

As the carrier is estopped from disclosing information relative to a shipper's business to his competitor, so, too, the shipper soliciting such information as may be detrimental or prejudicial to his rival subjects himself to a fine of $1000.

Conclusion

The effectiveness of any law is wholly dependent upon the public support that lies back of it. The Act to Regulate Commerce as it now stands is one of the most concrete expressions of the broader social sense of justice that has grown up in this country within the last few years. It is an index to an awakened business conscience, a reaffirmation of the age-old principle that you cannot build lasting success on the advantages you may unjustly take of your neighbor. Many of the practices now condemned in this statute were frankly recognized a decade ago as shrewd business and proof of commercial acumen. It is more than possible, in the light of past experiences, that certain of the practices that today bear the stamp of legitimacy, tomorrow may be crossed with the bar sinister. But, whatever the changing ideas of business morals may bring as to specific performances, it is inconceivable that there should be any departure from the fundamental purposes of equality of opportunity as expressed in this act. The instruments of guarantee for this equality, full publicity and strict adherence to the published rates, have proven adequate to the needs of the times. The soulless corporation is still run by living men who will still err as in Pope's day, who still will look at things from different angles; the mistakes of the past have not all been wiped out; the sins of the railroads and industrial fathers not all canceled by their children and new wrongs are bound to intrude from time to time in the relations between the transportation industry and commerce at large. But the machinery of redress is there.

To the shipper who knows his rights, such wrongs can only be temporary and prompt action will save him from permanent financial scars. His right to redress and relief, however, is still predicated upon that doctrine of universal application, that he must come into court with clean hands. Translated into direct terms of transportation this means that he must know his rates; he must pay them; he must adopt no device, however legal it may be, that will defeat the published rate; that will enable him to obtain his services at less than this rate. Having thus established his title to justice, he can stand at the bar and demand it.

Coal Rates to Chicago

The Peabody Coal. Co.'s monthly, "Coal Trade Sparks," describes Indiana and Illinois freight rates to Chicago as follows:

	Number of Billing Points	Freight Rate per Ton
Indiana		
Clinton and Brazil	29	$0.77
Linton	75	0.87
Princeton	15	0.94
Booneville	11	0.97
Evansville	1	1.27
Illinois		
Montgomery County	6	0.82
Central Ill. (Springfield)	63	0.82
Du Quoin	11	0.97
Belleville	72	0.97
Southern Ill.	48	1.05

Wage Negotiations in Central Penn.

The following letters were submitted to the miners' scale committee by the Bituminous Operators of Central Pennsylvania. They refuse to consider the check-off, and request a reduction of 10 per cent. in wages.

LETTER No. 1

Du Bois, Penn., Mar. 3, 1914.

TO THE SCALE COMMITTEE OF THE UNITED MINE WORKERS OF AMERICA OF DISTRICT NUMBER TWO:

WHEREAS, under the terms and conditions of the various scale agreements entered into for many years between the Operators and United Mine Workers of America, the operators have been compelled to collect from their organization employees, in one form or another, the dues and assessments levied by the United Mine Workers of America, which system of collection is commonly called the "Check-off"; and

WHEREAS, During the past few years at various intervals extra assessments were laid or levied by the United Mine Workers of America on its members for the purpose of maintaining strikes at other points or in other states, with the demand on the operator to collect the same, which caused more or less dissension and controversy, strikes and suspensions in our own region; and

WHEREAS, legal action has been taken in some of the states against the United Mine Workers of America for such action, alleging a conspiracy between operators dealing with organized labor and the United Mine Workers of America; and further actions have also been threatened as disclosed by newspaper reports; and

WHEREAS, the check-off system has become so serious, unreasonable and un-American from the abuse or misuse on part of the United Mine Workers of America as to make its abolition necessary.

THEREFORE, BE IT RESOLVED, That the Association of Bituminous Coal Operators of Central Pennsylvania, through its Scale Committee this day assembled, do hereby demand from the United Mine Workers of America of District Number Two, an elimination of all such check-off provisions or clauses from all future scale agreements, and that hereafter the operators shall not be required in any manner to collect in any form from its organized employees any dues or assessments that may be levied or laid on said employees by the United Mine Workers of America.

LETTER No. 2

Du Bois, Penn., Mar. 3, 1914.

TO THE SCALE COMMITTEE OF THE UNITED MINE WORKERS OF AMERICA OF DISTRICT NUMBER TWO:

WHEREAS, the coal operators of central Pennsylvania, doing business within your district and with organized labor, have granted the miners of said district, from time to time during the past fifteen years, increases in wage rates amounting to 50%, which has resulted in the highest wage that has ever been paid to the miners in the history of this district; and

WHEREAS, during said period of fifteen years, the cost of producing coal, outside of the question of wages, has more or less likewise increased, produced by increased cost of material and new mining and other laws, both state and national; and

WHEREAS, the competition from the nonunion or unorganized coal fields, which work on a lower wage basis, is just as keen and severe as it ever was with the operators of the Central District of Pennsylvania; and

WHEREAS, during said period of fifteen years, the average selling price of bituminous coal in the markets, eliminating one or two temporary flurries, has rather decreased than increased, and the operators are further prohibited by the Sherman law from forming any combination to regulate the selling price of coal; and

WHEREAS, a contract was made and entered into on Apr. 20, 1912, between said operators and miners whereby a 5% increase in wages was granted to the miners who therein guaranteed that the operators should have the right to work their mines on the open-shop basis, and, notwithstanding such contract, the miners at numerous mines throughout the district refused to work with nonunion men, demanded an absolutely closed shop which resulted in a large number of strikes likewise in violation of said contract and thereby materially interfered with the business of said operators in not only a loss of trade, but also in the increase of expenses; and

WHEREAS, since about Oct. 1, 1913, a decided slump has taken place in the general business of the country and especially in the coal business to such an extent as to enable the large consumers who make their annual contracts for a coal supply based on normal business to accumulate large surpluses or stock piles of coal, thereby resulting in a general stagnation of the coal business to such an extent as to make coal a drug on the market, large accumulations of unsold coal at the mines and only about half time for the miners; and further that the coal business is showing a steady decline, and that the large amounts of surplus coal in the hands of the consumer do not argue for an upward turn in the near future; and

WHEREAS, the burden of depression of business conditions must be recognized and born mutually by the miners and operators of this district.

THEREFORE, BE IT RESOLVED, That the Association of Bituminous Coal Operators of Central Pennsylvania, through its Scale Committee this day assembled, do hereby demand from the United Mine Workers of America of District Number Two, a general deduction of 10 per cent. from the wages paid under the scale agreement of Apr. 20, 1912.

The Slack-Coal Problem in Colorado

BY CARSON W. SMITH*

There is beginning to be a slack problem in the northern Colorado lignite field, which is becoming more serious each season. The market for this grade of coal is becoming steadily more restricted and actual losses are sustained in handling it during at least one or two months of the year. From an economic standpoint, it is essential that the slack be sold at such a figure that it will carry its proper proportion of the operating costs.

The standard grade of slack in this district is that passing through a 2½-in. screen, the portion passing over the screen being sold as lump coal. While this slack makes an excellent steam fuel, the demand from this source has been steadily decreasing for some time. This is probably due principally to the incursion of electric power into its market, some of the mines themselves having adopted this. In fact, the principal demand for slack coal now comes from sources where the requirements extend over a portion of the year only, such as the beet-sugar factories, heating plants in the cities, canning factories, etc.; the fluctuating character of this business naturally results in unstable market conditions. Thus a market in which substantial premiums prevail may be abruptly changed, due to a sudden heavy demand for lump coal, which naturally results in an excessive production of screenings, with the result that the situation is rapidly reversed.

Normally, the margin of profit on this grade is small, while car shortage, inadequate methods of storage and deterioration are all factors tending to complicate the problem. Occasionally, the slack is dumped on the ground alongside the track at costs, including shrinkage, waste, etc., ranging from 25 to 50c. per ton, although this might be accomplished at a cost of about 10c. per ton. While a more comprehensive plan for doing this on a large scale would do much to establish a more equitable market, this would involve some uncertainty, as, for instance, the danger from spontaneous combustion (lignite coal firing easily), while elaborate and extensive equipment would be required. There is also the ever-present tendency to take a gambler's chance on the possibility of real-

*Consolidated Coal & Coke Co., Dacona, Colo.

izing a higher figure for the slack coal each succeeding season.

More Careful Sizing

It has also been suggested that a broader market for the slack coal might be obtained by a more careful sizing, say, for instance, rescreening into nut and pea coal. This has never been done heretofore, and, in fact, there are grave physical reasons for doubting the practicability of such a scheme; for instance, it is doubtful whether the breakage and disintegration incidental to loading, shipping and delivering would not cause this lignite coal to deteriorate until it was practically worthless.

This would certainly be the case if the coal is handled over the ordinary shaking screen and loaded in open railroad cars; but if it were put through suitable revolving screens and carefully deposited in the cars by means of loading booms and, say with the nut coal in closed cars, it is probable that a satisfactory product could be shipped in cold weather in any event. It is quite possible that some such plan will be tried in the near future, in which event the nut coal will be sold as a domestic grade and the pea coal as a superior steam fuel, the remainder of the screenings being thrown away. This seems to be a logical solution for the problem, providing a satisfactory market can be developed for the nut and pea coal, and it should result in a reasonable profit

There is also the possibility of briquetting the slack coal, and it is not improbable that this may develop into an important industry in the near future. This would, of course, result in the slack coal being utilized in the domestic trade, for which purpose it is now entirely unsatisfactory. One of the most important advantages of such a condition would be that the necessity for having a market for steam coal would be eliminated, and the electric power would have this latter field to itself. Such a readjustment in fundamental conditions as this would, of course, involve enormous expenditures for additional equipment, and it is unlikely that such will be attempted for the time being.

Underground Storage

The third solution of the difficulty is the storage of the slack coal underground. It is claimed that this is entirely practicable, and that large tonnages could be conveniently accumulated in many of the lignite mines and at little cost. It will not deteriorate so rapidly when stored underground, nor will the waste or shrinkage be so great, but there will be the danger of spontaneous combustion.

This plan provides for loading the coal at the working face with "harps" or screening forks, throwing the finer sizes back against the rib. Of course, a readjustment in the basis of payment would have to be made in order to reimburse the miner for shooting the unloaded portion, and the cost of reloading this when required would also have to be reckoned in. Suitable rooms in the mine would have to be selected, preferably new ones, having relatively little refuse and gobbed so that the slack could be thrown back and left for several months, if necessary. The number of places to be worked thus could be gaged according to the demand for slack coal at the time; and it would seem that there is no theoretical reason why such a method should not operate successfully.

It is naturally to be expected that an innovation of this character will develop problems in working out the details in practice, but it is difficult to foresee any of a serious character; and it is quite probable that if many of the operators would investigate the marketing of their slack coal, they would find an explanation for their reduced profits.

BY THE WAY

The shortest answer is to do it.

It is often better to bend than to break.

Don't think a royal crown will cure a headache.

Water down in the well does not quench thirst.

The water runs smooth where the river is deep.

Little troubles speak loudest; great cares are dumb.

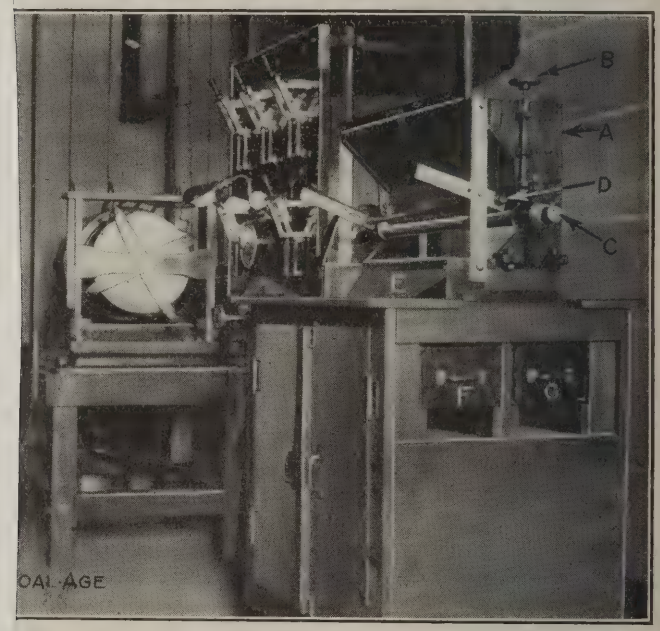
It's not so hard to catch the mouse that has but one hole.

We can't gather roses without being pricked by the thorns.

Many men go wool-gathering and come home shorn themselves.

The fellow who wears the shoe knows best where it pinches.

Cleaning Anthracite by the Huff Electrostatic Process



HINGTON*

s necessary as the particles get in the way of one another nd it is impossible to make a complete separation on ne electrode. For most coals it should not take more han four electrodes, as shown, to make the two final roducts—clean coal and tailings.

It is possible to treat the very fine sizes such as "slush," silt" and "dirt" (local names for culm) on a machine omposed of slides or chutes, but with this apparatus, the nly moving part would be the feed roll.

Description of the Apparatus

A machine having the revolving electrodes 30 ft. long nd built double (3 ft. 6 in. wide), as shown in Fig. 1,

IG. 2. Experimental Apparatus Now Installed

The process in its application to coals consists in effecting separations of such impurities as slate, bone, sulphur, iron phosphorus, etc., by utilizing the difference in electrical conductivity of these ingredients; it is accomplished without water and regardless of specific gravity or magnetic quality. Fig. 1 illustrates the principle of the process as applied in a field machine. The coal is fed to a hopper with an adjustable gate, which allows an even feed of a stream one or two particles deep to the first roll or "electrode" directly below.

The revolving electrode consists of ordinary steel shafting, 1½ in. in diameter, opposing which is a non-rotating electrode; means are provided for regulating the distance between these electrodes. As the mass of coal, slate, bone, etc., passes through the electrical field between the electrodes, the conductive particles are repelled or thrown out over an adjustable divider while the nonconductive remain inert and drop down to another electrode, where they are subjected to similar treatment. This repetition does not require more than two horsepower, electrically and mechanically, to operate. The capacity of the machines varies, for the same reason as does that of any jig or other concentrating apparatus, with the size of material treated. In cleaning No. 3 buckwheat, one machine should handle 150 tons in twenty-four hours.

The electrical set, for producing the electrostatic fields, consists of special generators and transformers, but of standard construction and capable of steady commercial use. In separating ore they are in use twenty-four hours per day and seven days a week. A three-horsepower motor drives the set. Fig. 2 shows the switchboard, and to the left a generating set capable of supplying a plant of 500 tons capacity. This outfit, which takes up little space, is capable of generating 35,000 volts, but at low amperage, thus eliminating danger in the operations. To the right of the switchboard is shown a one-electrode coal-testing machine, driven by a one-quarter horsepower motor (inclosed). *A* is a feed hopper of 50 to 75 lb. capacity. *B* is an adjustable feed gate which can be raised or lowered according to the size of material and the

*Harris Laboratory, 86 Fulton St., New York.

thickness of feed desired. *C* is the revolving electrode of the same diameter as used in a field machine. *D* is the opposing adjustable electrode, also of the same diameter as used in a field machine. The distance between the electrodes is varied according to the size of the material being separated.

For separating coarse particles the electrical field should be strong in order to repel and attract the conductive material over the divider *E*, to accomplish which, the opposing electrode is brought in close proximity to the revolving one. *F* is a drawer containing the conductive clean coal product which has been repelled over the divider *E*, while *G* is a similar drawer containing the nonconductive elements, slate with more or less bone. Divider *E*, being adjustable, may be set to obtain any grade of product desired, or, in other words, a high or low recovery. A low recovery of very clean material may be had, or a much higher recovery with corresponding decrease in grade may be obtained by the adjustment of this divider.

Method of Operating

With this electrical apparatus, which is the counter part of that in use in a number of large plants, and conditions the same as in the operation of a 500-ton commercial plant, the feed and electrodes of the same diameter as those in the field machines, accurate tests can be made on a small sample of 150 lb., the results of which can be relied upon to be duplicated in field or commercial work.

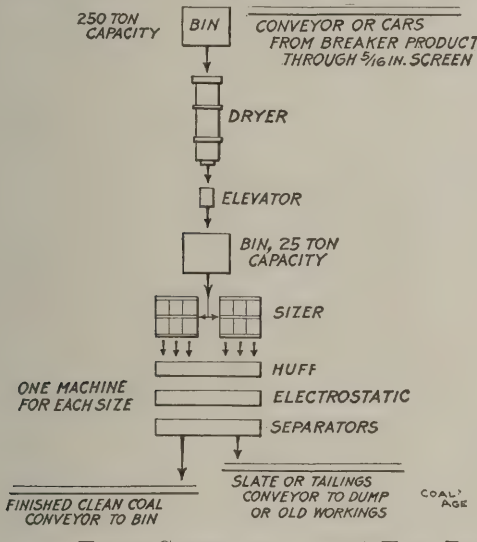


Fig. 3. Flow Sheet for a 500-Ton Plant

The one-electrode testing machine makes it possible to sample the products each time they are treated or separated, and also if found necessary, to have an analysis made before rerunning the clean coal product. By adjusting the chutes in a field machine almost any grade of coal can be treated, as the process is simple and flexible, and requires no special attention.

Due to its compactness, an electrostatic plant can be built adjacent to a breaker and by means of a conveyor belt or cars all the product mined and passing through a $\frac{3}{8}$-in. or $\frac{5}{16}$-in. screen can be treated. Fig. 3 shows a flow sheet of a proposed 500-ton plant. Coal comes from the breaker after passing through a $\frac{3}{8}$-in. or $\frac{5}{16}$-in. screen, is dried, and separated in the electrostatic machine. Practically all the moisture must be eliminated, as water is a good conductor of electricity, and makes the slate and other impurities conductors. This leaves a dry material of maximum heat units.

Anthracite coal running from 15 to 25 per cent. ash (slate) can be successfully cleaned electrostatically, as this slate has much less electrical conductivity than the coal (carbon) which latter has excellent conductive properties. The coal can be dried on this scale for less than $1\frac{3}{4}$c. per ton, an insignificant amount in comparison to the enhanced value of the dry finished product. This cost of drying includes labor, power, fuel and depreciation.

From the rotary dryer, the coal passes to a sizer from which three or four sizes can be obtained from the same machine, or more if necessary. The greater the number of sizes made, the corresponding lessening of the capacity. As the sizers can be placed on the top floor of the plant, the products are piped to the electrostatic machines on the floor below. The same is true of the electrostatic process as of any other concentration or separating process; i.e., the closer the sizing, the better the separation. After passing through the machines and the two final products are made—finished coal and refuse—conveyors take the cleaned coal product to storage bins while the slate can be flushed back into the old workings.

Some Advantages of the Electrostatic Process

By the electrostatic process not only can practically all the coal be saved, including that which passes through a $\frac{3}{32}$-in. screen, but the ash content is so reduced that the product can be sold on an absolutely guaranteed ash-and-moisture basis, the ideal method of purchasing. This kind of coal naturally commands a higher price since it is a much superior product. The ash-disposal charge is greatly diminished, the freight lessened, and the B.t.u. value per ton increased sufficient to effect a reduction of from 10 to 20 per cent. in the coal consumption.

The large consumers in New York City using Nos. 2 and 3 buckwheat, rice and barley, buy from 7 to 10 per cent. moisture and from 15 to 20 per cent. ash in their coal. Electrostatic separation should deliver this material with the moisture content practically eliminated, and the ash reduced to 10 per cent. or less.

No doubt a method will eventually be devised to burn direct (instead of briquetting) the clean coal from culm, which in general amounts to about one-half of the total product passing through a $\frac{3}{32}$-in. screen and, after electrostatic separation, runs less than 11 per cent. ash. A reason anthracite briquettes have not found a ready market is that they contain from 18 to 25 per cent. ash, which as the briquettes disintegrates chokes the fire much more than when burning stove or chestnut size. With the ash content reduced from 25 or 30 per cent. to 10 or 12 per cent., not only a better grade briquette can be produced but one having a much higher heat value will be obtained.

Thus this electrostatic method, which is just beginning to attract attention in the coal world, should prove of great value to those having to deal with the finer sizes of anthracite. Its application to the bituminous fields will be described later.

To anyone interested in seeing the apparatus shown in Fig. 2 in operation, invitation is extended to call at the Huff Electrostatic Separator Co.'s office and laboratory, 60 India St., Boston, Mass. The same method in a large-scale use may be seen in the metalliferous mining regions.

Miners Uphold Linker Docking Law in Pennsylvania

A legal battle to determine the status of the Linker Docking law was started by the United Mine Workers when the organization caused the arrest of Superintendent Walter Fahringer of the South Side Division of the Lehigh & Wilkes-Barre Coal Co., charged with its violation. Superintendent Fahringer waived a hearing before Squire McShea, at McAdoo, Penn., and entered bail for his appearance at court.

For many years the coal companies have docked for dirt and rock when the cars reached the breaker. The Linker act, which is said to be generally ignored in the anthracite field, provides that the miner must be paid for his coal when it is mined at the face. If docking is to be done, there is where the charge must be made.

The State Senate amended the act so that it was not to operate in violation of any existing wage agreements between miners and operators. The latter have claimed that it does this, and hence they have not followed it.

Miners cite the charge that the Lehigh Valley Coal Co. docked its Yorktown miners at the Yorktown breaker until the structure was abandoned. Now the dockage is done at Jeanesville, which prepares the Yorktown coal. The men argue that if the company can change the place of payment to the miners, then the state legislature has the same power.

The Linker bill opens other avenues of dispute over dockage. If a miner is digging out coal, he is to be paid by the car. The United Mine Workers argue that if he strikes slate or rock and must cut it out he is compensated by the yardage on another agreement. Since this is the case, the miner is entitled to either pay for cutting rock or pay for mining coal.

The Linker act is designed to prevent thefts of cars of coal. One man of the Lehigh & Wilkes-Barre Coal Co. mines has shown the United Mine Workers' officials that he has lost eight cars at $2.22 each in two weeks. The contention of the organization that when a miner fills his car and the drivers, servants of the company, take it, it constitutes an acceptance of the car, has never been sustained. But the United Mine Workers assert that under the Linker Docking law, the car is receipted for as it arrives at the face of the breast, and theft of coal cars will be impossible.

A Record Output at a Pennsylvania Mine

Eighteen 100,000-lb. capacity steel railroad cars loaded in a single day, is the record output recently made by one motorman at Mine No. 1, of the Scalp Level Coal Mining Co., whose offices are at Windber, Penn.

On this particular day they worked exactly nine hours and 45 min. The only haulage equipment used was an 8-ton Baldwin-Westinghouse bar-steel electric mine locomotive, equipped with commutating-pole motors. This locomotive, except for a few mine cars hauled from a dip heading by a mule, did all the work, gathering the coal cars and hauling them to the tipple. When they stopped work in the evening the locomotive was inspected and found to be in first-class condition in spite of the heavy work it performed. The motors were nearly as cool as when they started in the morning.

Twelve mine cars, each loaded with two tons of coal, were hauled on each trip. The longest haul was about 2500 ft., from the face of the first-left entry to the tipple, and about the same distance from face of main heading to tipple. The grades in this mine at two points for a distance of 400 ft. are 1½ per cent. against the loads.

Thirty-six trips were hauled, and it is estimated that at least two minutes were lost on each trip on account of the motorman waiting for empty cars outside. Notwithstanding this loss of time the operators feel certain this was the highest run of coal ever made in western Pennsylvania in one day by one motorman.

The men at this mine claim that there was no extra effort made this day to make a record. It was only an ordinary day's work, and they believe that if they would make an extra effort, with every man on the jump, for any one day, this Baldwin-Westinghouse mine locomotive could gather and haul sufficient coal to at least load 24 steel cars.

Coming Society Meetings

American Mining Congress

A special meeting of the American Mining Congress, in accordance with a resolution adopted at the 16th annual session of the American Mining Congress, is called, to be held at 8 p.m., Mar. 26, Majestic Building, Denver, Colo. The purpose of the meeting is to adopt or reject an amendment to the by-laws, which proposed change, prepared by H. M. Chance, Eli T. Conner and J. Blair Kennerly, is designed to meet the recommendation of the Ways and Means Committee that some way be provided to furnish a larger fund, so that the work of the congress can be more properly carried on. The proposed amendment will accomplish this end through securing the support financially of the larger mining corporations by making such corporations "subscribing members" of the congress. These "subscribing memberships," however, will not be entitled to vote.

American Peat Society

The American Peat Society will hold its eighth annual meeting at Duluth, Minn., Aug. 20, 21 and 22. Papers will be read and discussed on all uses of peat, agricultural, fuel, industrial, etc. Julius Bordoilo, Sec.-Treas., 17 Battery Place, New York, N. Y.

Canadian Mining Institute

A meeting of the Rocky Mountain Branch of the Canadian Mining Institute is to be held at Fernie, Crowsnest Pass, British Columbia, Mar. 18 and 19. W. R. Wilson, general manager for the Crow's Nest Pass Coal Co., Ltd., is chairman, and John L. Stirling, provincial inspector of mines for Alberta, secretary.

The meeting will be opened on Wednesday, Mar. 18, when the chairman will deliver an address, following which several papers will be read and discussed, as follows: "Mine-Rescue Apparatus," by Charles Graham superintendent for the Corbin Coal & Coke Co., Corbin, B. C.; "Mechanical Equipment of Collieries," by N. C. Pitcher, Lethbridge, Alta.; "Certain Classes of Faults Encountered in the Crowsnest Pass District, with their Correlative Effects on Economic Mining," by W. R. Wilson; "Shaft Sinking in Edmonton Coal Field," by E. I. Roberts, Evansburgh, Alta.

Papers read at earlier meetings of the branch, namely those of J. Somerville Quigley, manager for the Hillcrest Coal & Coke Co., Hillcrest, Alta., on "Methods of Driving Pillars in Pitching Seams"; C. C. Richards, of Edmonton, Alta., on "Field Notes for an Underground Survey"; M. L. Hyde on "Important Details in Connection with Construction of Colliery Plants"; N. C. Pitcher, on "Preliminary Costs of Machinery for Colliery Work"; and of Francis Aspinwall, district inspector of mines, Lethbridge, Alta., and Andrew A. Millar, manager for the Pacific Pass Coal Fields, Ltd., Fergie, Alta., on "Mine-Rescue Apparatus and the Value of Mine-Rescue Work," will also be open for discussion.

Editorials

Pertinent Supreme Court Decision

The Supreme Court of the United States has recently handed down a verdict affirming the judgment of the lower court rendered by the late Judge Ferris, in what has become known as the Barrier-Pillar Case.

The anthracite-mining law, Art. 3, Sec. 10, requires the leaving of a sufficient barrier pillar between adjoining coal properties, sufficient to provide for the safety of the employees in those mines. It is stated that the mine inspector of the district, David T. Davis, Aug. 3, 1909, notified the Plymouth Coal Co. and the Lehigh & Wilkes-Barre Coal Co., operating adjoining mines in Plymouth, that the barrier pillar required by law must be left in their respective adjoining workings. By law, Mr. Davis, together with the engineers of the two companies, constituted the board to determine the size of pillar that should be left to comply with the statute. They failed to arrive at any agreement; and, as a result, Mr. Davis, in the following October, filed a bill in equity, in the court of Luzerne County.

This case, which, at the present time, has an important bearing on other mining decisions, was heard by Judge George S. Ferris, now deceased. On the claim of Mine Inspector Davis that a 70-ft. barrier pillar should be left between the workings of these companies, Judge Ferris so ordered. An appeal from this decision was taken by the Plymouth Coal Co., and the case went to the Supreme Court of Pennsylvania.

It was claimed by appellant that the requirement of the anthracite law in question was not in harmony with but contrary to the provisions of the fourteenth amendment to the Constitution of the United States and Art. 1, Sec. 10, of the Constitution of Pennsylvania. These laws are as follows:

Anthracite mining law, approved by Governor Robert E. Pattison, June 2, 1891, Art. 3, Sec. 10:

It shall be obligatory on the owners of adjoining coal properties to leave, or cause to be left, a pillar of coal in each seam or vein of coal worked by them, along the line of adjoining property, of such width, that taken in connection with the pillar to be left by the adjoining property owner, will be a sufficient barrier for the safety of the employees of either mine in case the other should be abandoned and allowed to fill with water; such width of pillar to be determined by the engineers of the adjoining property owners, together with the inspector of the district in which the mine is situated, and the surveys of the face of the workings along such pillar shall be made in duplicate and must practically agree. A copy of such duplicate surveys, certified to, must be filed with the owners of the adjoining properties and with the inspector of the district in which the mine or property is situated.

Fourteenth amendment, Federal Constitution:

No state shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any state deprive any person of life, liberty or property without due process of law.

Constitution of Pennsylvania, Art. 1, Sec. 10:

No person shall, for the same offense, be twice put in jeopardy of life or limb; nor shall private property be taken or applied to public use without authority of law and without just compensation being first made or secured.

The pertinent bearing, in this case, on present-day mining operations in the anthracite field, relates to the contention of the company that under the provision of the Anthracite law the private property of the coal company was appropriated to public use, namely, the protection of the lives and properties of the community and no compensation was provided for the owner of the coal left for this purpose. It was claimed that this was an illegal exercise of the police powers of the state.

Judge Ferris, in rendering his decision, from which the appeal was taken, discussed broadly this contention of the appellant company, stating in words that are memorable:

The principle is equally vital, because it is essential to the peace and safety of society that all property in this country is held under the implied obligation that the owner's use of it shall not be injurious to the community; therefore, the act of 1891, under which this case was brought, was a valid exercise of the police powers of the state.

Without going further into the details and merits of the barrier pillar case, we would draw attention to the application of the principle involved in that case, as recently made by City Solicitor David J. Davis, who is resisting, at present, the appeal taken by officials of two of the largest coal companies in the anthracite region. The city solicitor claims with much justice, we believe, that the principle of equity laid down by Judge Ferris, in the former case, applies with equal force to the protection of the lives and properties of communities residing on the surface overlying coal seams from which the mineral is being extracted.

It is a large question and one to which COAL AGE has referred previously as involving "a clash of equities." The law defining the equal rights of surface holders and the possessors of underlying mineral claims has yet to be clearly defined. It cannot be decided briefly or offhand, but must be worked out with due regard to justice and the equal rights of the parties concerned.

The principle, however, of the *paramount importance and value of human life and health, in its relation to individual or corporate rights,* is unquestionable. Any law that ignores this principle is unstable and must eventually be annulled.

A Lean Winter for the Coal Companies

Following a summer period of almost unprecedented activity, the coal trade has experienced a winter season of equal depression. The trouble seems to have been due to a combination of adverse conditions, such as the general wave of retrenchment in all lines of industrial activity, and to the peculiarly mild temperature prevailing throughout the country during most of the season. Under the compelling influence of these determining factors, the coal trade has rounded out the year in a most disappointing form.

It is likely that even the most consistent pessimists have failed to realize the full proportion of the curtail-

ment, upon which a study of the performance of some of the leading coal roads offers some interesting thoughts. The Pennsylvania Railroad, the largest bituminous-coal road in the country, showed a substantial increase in fuel shipments all through the year 1913 until the break occurred in December. Until that time the total shipments over this road for 1913 amounted to nearly 70 million tons, as compared with 63½ million in 1912. But December shipments for 1913 were 300,000 tons less than in 1912, while in January the movement for the current year was 600,000 tons less than the same month last year. A sudden decline in the shipments is noticeable, beginning with October; in that month 7 million tons were handled, 6½ million in November, 6¼ million in December, and less than 6 million in January. The other bituminous coal roads reflect substantially the same conditions.

Because of the shortage of some six million tons as a result of the six weeks' suspension in mining in the early part of 1912, a comparison of the monthly shipments of anthracite cannot be made fairly with the movement in 1913. However, it is a significant fact that the total shipments for the year 1913 fell short of those for the last previous normal year, 1911, by nearly a million tons. The meager shipments of 4½ million tons in January of this year, the lowest made during any normal month since September, 1909, speak eloquently of the adverse conditions in hard coal. Turning to the earnings of the Reading company, we find still additional light on this subject. January receipts for the current year were $2,836,047, as compared with $3,680,572 for January last year, while profits for the same periods were $95,359, and $560,356, respectively.

A glance over the coal-car supply statistics substantiates still further these conclusions. When the peak of the load was reached in mid-October, a net shortage developed which continued until Nov. 1. But during the closing two months of the year, the surplus of coal equipment was more than doubled each two weeks, finally reaching over 86 thousand on Jan. 15—a figure scarcely exceeded during the suspension in both the anthracite and bituminous fields in April, 1912.

But even in the face of these adverse conditions, there are hopeful possibilities in the future. It is noted, for instance, that free tonnages of demurrage coal are not being indiscriminately dumped into a market totally devoid of any absorbing power, in the manner characteristic of previous dull seasons. There are also many who rightly argue that the possibility of a suspension in the bituminous field Apr. 1, will have an important psychological effect upon the trade. Whether this materializes is dependent entirely upon the pending negotiations.

Opinions as to the outlook in this regard are about as inconsistent as in former years. The possibility of a suspension of more or less long duration seems to be about equally balanced, although the opinion of those best informed on the subject seems to be that a shut-down of at least short duration is inevitable.

The British Fatality Rate

The British fatality returns are always based on two different methods of computation. One is concerned with separate fatal accidents and the other with the number of lives destroyed by such untoward occurrences. While tables like the latter may be unduly swelled by one or two severe explosions, hoisting accidents, inundations, airblasts or mine caves; the former must always remain in some ways a fairer index of mining conditions.

As an example of the dependence of the total fatality rate on the casting of a die, the Bicknell explosion in the state of Indiana at the close of last year is a case in point. It evidenced that the mine was in a dangerous condition just as clearly as if it had killed almost a full shift of men. If the mine had been working with the full quota, few would doubtless have been saved. Only chance prevented it from making a much larger addition to the death rate of last year.

The number of separate fatal accidents in Great Britain was greater by 59 in 1913 than in 1912, an increase of 5.13 per cent. This was probably due to the greater number of days the mines were operated. In fact, the fatal accident rate per month really improved even if we assume that the British strike in 1912 only lasted a month. It actually exceeded that period about a week everywhere and in some places a longer time. A 4 per cent. improvement per month would be shown if the figures were based on a month's suspension.

But the increase in fatalities enumerating not separate accidents but individuals killed cannot be thus reasoned away, for explosions of coal dust or firedamp while numbering only 12 caused 461 men to lose their lives. Thus the loss of life mounted from 1276 in 1912 to 1742 in 1913, a gain of 466.

The Senghenydd explosion was, of course, largely the cause of this increased death rate, for in it 434 men lost their lives. It was the sole catastrophe of magnitude in Great Britain in the year except a much smaller accident at the Rufford shaft. Unfortunately we, in the United States, cannot point to as good a record in 1913. Our death list seems to point rather to decreased safety and only what we know about the efforts being made everywhere to make mining safe, gives us certain assurance that there is more cause for perseverance than there is for alarm.

Arbeitswillige

A labor agitator in Germany must not use any such opprobrious title as "strike-breaker." He must term such a man an *"arbeitswillige,"* a man who is willing to work. The Teutons are as sensitive to mere language as we are. How we also shrink from that word, "scab," which expresses a man who is willing to work when and where his mates are unwilling?

Much usage in unpleasant association will make *arbeitswillige* as offensive as strike-breaker, but this mil substitute of the Germans must be used with due discretion to persons only who are offenders against the moral sense of the public, or it will have as little meaning as "mugwump," which was a word to conjure with in the eighties and nineties and now is like "abracadabra," a relic of a past superstition.

If *arbeitswillige* is used to express disdain, the last estate of society will be worse than the first, for a willingness to work under all conditions will be regarded as evil. Are not *arbeitswilligen* altogether too rare in all countries, especially among the well-to-do?

D. A. Thomas Back Again

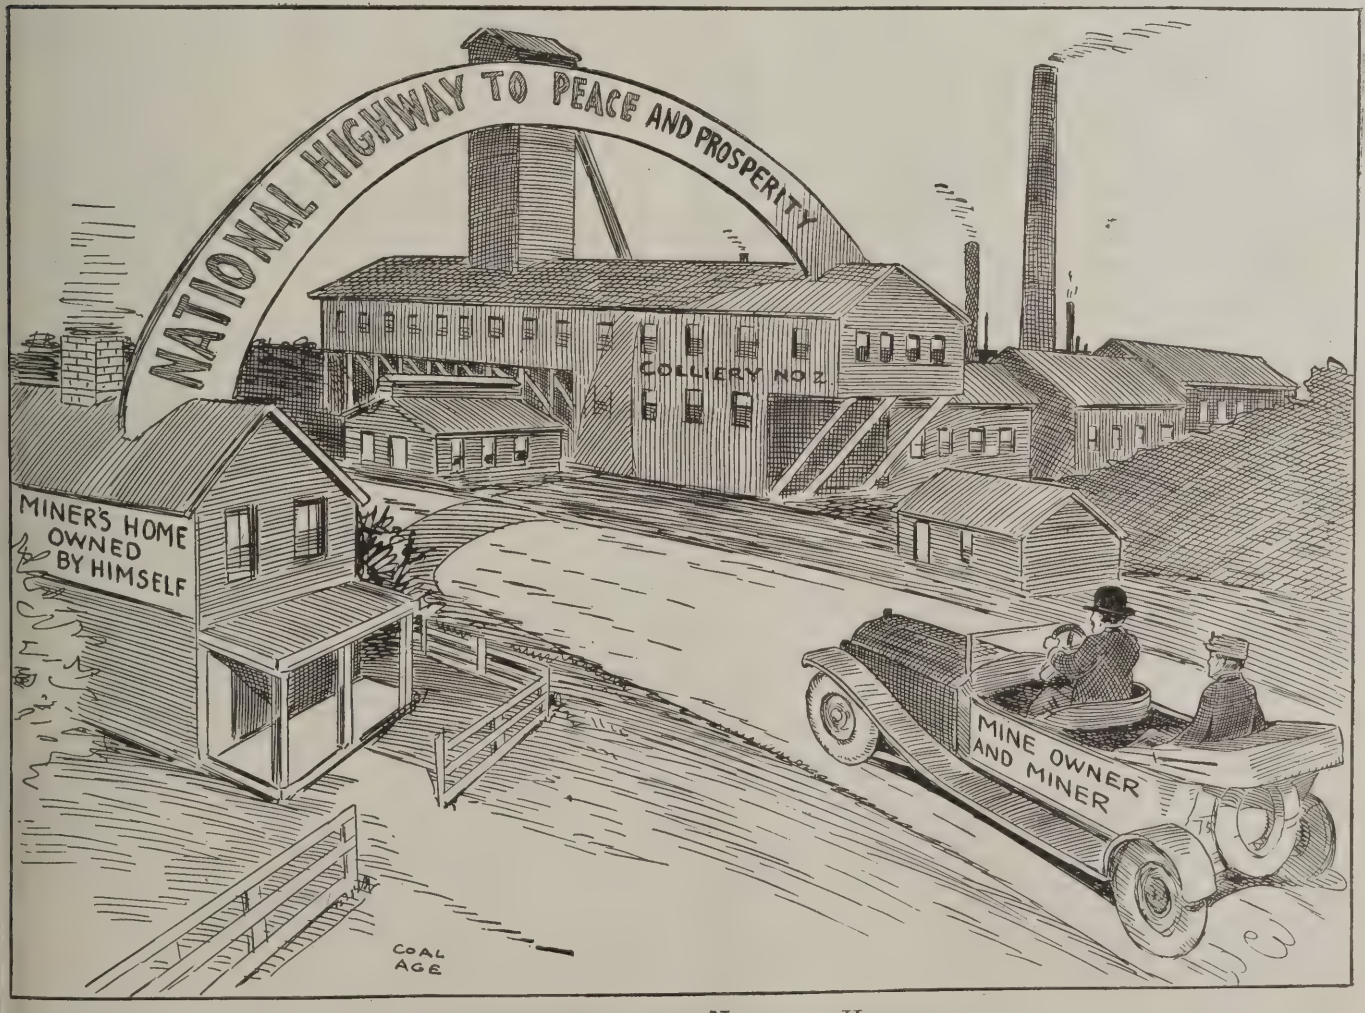
The New York *Evening Journal* publishes the following interview with the English coal man:

D. A. Thomas, the Welsh coal magnate, who made two visits to America last year to look into the coal resources of West Virginia, with a view to acquiring coal properties here, arrived from England Mar. 6. Mr. Thomas stated that his visit is not for the immediate acquirement of more coal properties in West Virginia, but to complete arrangements for the building of a 1500-mile railroad in northwest Canada.

Accompanying Mr. Thomas on the Lusitania, were several Canadians, with interests in the Northwest, and he is to be joined in New York by other capitalists interested in the building of this road, which will open up a vast territory. The line will be known as the Pacific, Peace River & Athabasca R.R. Mr. Thomas became interested in this proposition when he made a visit to the Northwest last year. The road will pass through a large coal area, not at present developed, known as the Ground Hog* coal fields, and as these lands lie near the Pacific, Mr. Thomas sees possibilities of placing the coal in the Pacific markets and said further:

"My interest in producing coal in Wales, is secondary to my interest in coaling depots all over the world. I recognize that if I am to keep them going successfully, I have to look ahead for supplies. The unsettled labor conditions in the Old World make it all the more imperative that I look to America for coal for the future. The labor situation in England is very much unsettled, and I would not be surprised if we have serious trouble with the miners in 1915."

Asked about the action of certain Congressmen from coal-producing states in urging the United States to enact legislation prohibiting the sale of any but American coal on the Panama Canal, Mr. Thomas said: "Such legislation is entirely unnecessary. Panama is the natural outlet for American coal, and American producers will unquestionably reap the benefits that will accrue through the operation of the new waterway. When one considers that in the past ten years, American coals have supplanted Welsh coals in the West Indies, one does not need to give serious consideration to the fear of competition at Panama from Welsh or German coals.



AMERICAN COAL AND THE PANAMA CANAL

"The canal will play an important part in commerce, and I am therefore giving it a great deal of study. To have my coal interests international appeals very strongly to me, and I am hoping to extend my operations from time to time, so that my producing interests will be situated so advantageously from a geographical standpoint that my coaling depots will be assured of a constant supply of coal and at competitive prices, no matter where they may be located.

"I see a great future for your better grades of American coals from the operation of the Panama Canal. Your coals are at present impregnable so far as the West Indies are concerned. The west coast of South America will take a great deal of tonnage from American shippers when the canal is opened up, while at the present moment Americans are increasing their shipments to the east coast of South America and to the Mediterranean."

*For a brief description of this district see "Coal Age," Vol. 3, p. 993.—Editor.

Duty to Warn Miner Against Danger—In a suit for injury to a miner, received in a mine explosion, caused by the lamp on his cap coming in contact with a charge of dynamite which his foreman had inserted in a hole in an overhead timber preparatory to blowing the timber out, the jury were warranted in finding that there was negligence in failing to warn the man against the danger, although he knew that the hole had been drilled in the timber for the charge; he having no knowledge that the explosive had been inserted. The foreman shouted a warning just too late to avoid the accident. (United States Circuit Court of Appeals, Second Circuit; Pennsylvania & Reading Coal & Iron Co. vs. Keslusky, 209 Federal Reporter, 197.)

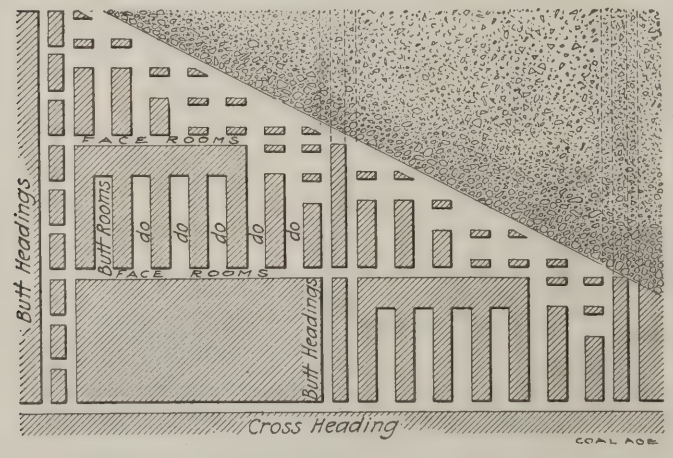
Discussion By Readers

An Acknowledgment

I wish to take this opportunity to thank you for publishing my inquiry in your issue, Jan. 5, p. 30, relative to water-bearing strata over a coal bed. The discussion by your readers was very helpful. After we have developed our mine I shall be glad to correspond with anyone who desires the benefit of our experience.



GEORGE MACPHAIL, Engr.,
What Cheer Coal Mining Co.

Bay City, Mich.

Longwall Mining Methods

Letter No. 7—Referring to the inquiry of "Bituminous," in regard to methods of longwall mining, in my opinion, the kind of longwall best suited to the conditions described would be a modified room-and-pillar system that may be described as follows:

The work is begun by developing a full section of eight pair of butt entries, or headings, driven on 300-ft. centers and forming a longwall face of, practically, 1400 ft. in length, a portion of which, only, is shown in the accompanying figure. Starting at the inby corner, or at the

A LONGWALL FACE, RETREATING SYSTEM

head of No. 1 or No. 8 butt entry, as the case may be, and retreating, face rooms are turned off the even butts only. These face rooms are turned on 120-, 140- or 160-ft. centers, depending on conditions. In the present case, I would drive the face rooms on 140-ft. centers.

Now, starting at the inby corner of the face rooms, butt rooms are driven on 42-ft. centers. These rooms are driven 21 ft. wide and 21-ft. pillars. In the retreating plan, the face rooms may be driven double, but care should be taken to drive the breakthroughs between them on the same centers, 42 ft. The butt rooms and breakthroughs may be driven while developing the face rooms, thereby increasing the production of coal, for the same cost of operation, and decreasing the cost per ton over what can be attained in the regular longwall-retreating system.

When Nos. 1 and 2 or Nos. 7 and 8 butts have been driven to the line or barrier, work is started on the retreating plan, by driving the butt rooms off the face rooms, on the upper side only, as described. The butt rooms are driven through the ribs, and three cuts are then made in the 21-ft. ribs separating them, these cuts being 18 to 20 ft. wide and leaving stumps of 7 or 8 ft., which are taken out at once with picks. The break line or line of fracture, is kept on an angle of about 60 deg. off the butts or 30 deg. off the face rooms.

This is an excellent system, in respect to economical haulage and ventilation. The air current can always be made to sweep the gobs, after passing the working face. The system has been tried and proved very successful, both on the semi-retreating and the full-retreating plan; but the latter, in my opinion, is the more satisfactory system to adopt, if given proper attention.

A similar system but worked with smaller entries and perhaps narrower rooms, can be found on the upper end of the Monongahela River, near Brownsville, Penn. The Bridgeport and other mines, in that vicinity, have tried a similar system that would have been more successful had they used longer rooms and greater entry centers. The system I have described gives an actual longwall-retreating face, with room-and-pillar development.

MINE FOREMAN.

Coal Center, Penn.

A Plea for the Mine Foreman

I noticed in your timely editorial, Mining Education, COAL AGE, Jan. 10, p. 96, a reference to the efforts often made by large coal-mining companies, to secure a large available list of candidates for the positions of mine foreman and fireboss, while there are but comparatively few of these positions to be filled. And when these qualified men ultimately secure the position they seek, it is to work for a salary that is generally less than the pay received by a hard-working miner.

During the course of several years in coal mining it has frequently occurred to the writer that one of the fundamental weaknesses of the usual scheme of organization at coal plants consisted in the lack of proper incentive to the right type of men to become mine foremen.

I consider the mine foreman to be the keystone of the whole mining system. He is, in point of law and in fact, in exclusive control of the mine. True, he is guided and directed by his superiors to a large extent; but I believe that most practical mining men will concede that the mine foreman has more direct control over the cost, tonnage, safety precautions, etc., than any other individual in charge. But the point to which I wish to draw attention is that the financial and social inducements that are offered to the man aspiring to become a mine foreman are, to say the least, not flattering.

In the mines with which I have been acquainted, there were men who made more money than their foreman, and

who were without responsibility other than their own safety, and whose social position in the community was as high as that of their foreman. It is not necessary to go into details of the worries, difficulties, trials and tribulations of the mine foreman. Mining men all know what he is up against. I think, too, that if one stops to consider he can but realize there is little inducement for a man to prepare himself for such a position. Mine foremen, as a class, do not make as much money as railroad trainmen. They must live as close to the pit mouth as possible, and often work seven days a week and 12 or 14 hours a day. The mine foreman is regarded by his men as directly responsible for most of their troubles, and is too often so regarded by his superiors.

When one stops to consider that it is financially more profitable to run a cutting machine, work six or seven hours a day and come out of the mine with no responsibilities to worry over until the whistle blows the next morning, he is forced to conclude that either there should be a division of the responsibilities that now rest so heavily on the mine foreman, or his pay should be more commensurate with the salaries of other mine officials and the prices paid for other labor around the mine.

Any foreman can save or lose twice the amount of his salary each month in material and coal lost or recovered; and the same is true of a number of items, the loss of which would not be discovered by his employers.

I believe that the position of mine foreman as at present understood, requires ability of a high order. It may be said to the credit of our faithful mine foremen that they have no labor affiliations to stand out for their assumed rights and privileges, but depend on their own merit and ability as true workmen.

Liquor and Safety in Mining

I have noted with strong approval some of the recent editorials and articles in Coal Age, relating to the evil effects of alcoholic liquors on mine workers. Being the owner of a small anthracite-mining operation, I have had some opportunity of noting these effects, which, I believe, if fully known to owners and managers of mining properties, would cause them to stand aghast.

For some time, I have been considering the advisability of writing a letter to mine owners in this district or even the entire hard-coal field, suggesting the calling of a meeting to discuss the liquor question in its relation to the safe operation of coal mines. It has even occurred to me that it might be advisable to select one or more engineers of experience in coal mining, for the purpose of making a careful investigation and inquiry into existing conditions in this regard and making a report that would show the exact relation of the liquor habit to safety in mining; and to make suggestions as to how the evil can be best overcome. I have hesitated to do this, because of the comparatively small interest I represent in the coal-mining industry. However, I write this letter in the hope that a way may be suggested by which the attention of those in control of the anthracite industry will be drawn to the matter and some action taken.

E. S. Stackhouse.

Shickshinny, Penn.

Mine Legislation, Ohio

Referring to the recent interesting compilation of statistics in reference to the production of coal for 1913, Coal Age, Jan. 10, I notice that, in several of the larger coal-producing states, the death and accident rates have materially increased. In our own state, Ohio, the increase in the death rate has been 25 per cent., notwithstanding the "safety first" campaign that has been waged so successfully throughout the state. One is led to wonder what might have been the result if these endeavors in the interest of safety in mines had not been undertaken.

The Ohio Legislature, now in session, have considered a number of measures having for their aim and purpose the safety of mining operations and the conservation of the coal. Among these measures may be mentioned the appointment of safety mine foremen; the regulation of solid shooting; and the provision of suitable emergency supplies in mines. The general tone of the legislation thus far passed by the assembly, under the leadership of Governor Cox, has given general satisfaction and leads both miners and operators to hope for the passage of further sane and uptodate measures relating to safety in the mines. This is more earnestly hoped and expected, since the law-making body turned its attention toward the coal business.

Operators should not object to the passage of laws looking to the safety of life or the conservation of natural resources because additional expense would be incurred by the passage of such laws requiring improvements in the equipment of the mine and methods of operating. Any increase in the cost of operation must necessarily fall on the consuming public. The anthracite tax in Pennsylvania will naturally be added to the price of anthracite. Any wage increase always means an increase in the price of coal to the consumer.

If the public demands these measures for safety, the public must be willing to stand the expense, and I believe that whatever additional expense is required to reduce the death rate among miners, or the conservation of the coal supply will be gladly met where it rightly falls. It must be conceded that the coal business must pay a living wage to the miner and a proper return to the operator.

George N. Lantz.

New Straitsville, Ohio.

Mine Legislation, Arkansas

It was with great interest that I read the article in Coal Age, Feb. 21, p. 314, entitled Safety in West Virginia. Although one or two of the rules given would not, perhaps, be applicable to coal mining in this state, I have seldom read a more complete set of instructions than what is there stated as "furnished to every mine foreman and assistant mine foreman." I am sorry to say that we have no such excellent rules and regulations in Arkansas.

Not to censure anyone in particular but with the hope of gaining better mining laws in this state, I submit a few facts that illustrate some of the conditions existing in all mines. The fact that these conditions exist is sufficient evidence that the state mining law is poor.

As has been mentioned in regard to other states, here also, too much is expected of the mine foreman. His

territory is too large to permit a daily visit to every working place in the mine. In many instances, the mine foreman's time is taken up with matters that should be looked after by someone else. He is obliged to devote much time each day to start an old pump working that is fit only for the scrap pile, instead of inspecting the working places and looking after the safety of the men in his charge. There are, I am sorry to say, some mine foremen who seldom go into the mine except on measuring days.

The fireboss, also, is required to cover too much territory. In many instances, he must examine in 2 hr. so many places that, if the examination were properly made, the work would require 4 hr. to complete. The fireboss often removes gas from the face of a room by brushing it out with a piece of canvas, regardless of the presence of any open lights. Everyone knows that such a practice is dangerous and that the gas should be removed by the air current only.

Speaking of brattices and stoppings, it cannot be said that we have any such things in these mines. There are what are called dirt stoppings," over which one can see into the next entry. Other stoppings are constructed of powder kegs, soft shale rock, sulphur balls, etc. These are the kind built on the main entries; in the rooms, there are no stoppings of any kind.

The rooms are driven up from 100 to 300 ft., and, in the latter case, there is sometimes a curtain hung on the entry to throw some of the air into the rooms; but this air is generally lost in the first crosscut 30 or 40 ft. from the entry, and never reaches the face. Where cross-entries are turned off the main entry, instead of a good door being hung on the entry, a curtain of 12-oz. ducking is used, which only throws a small scale of air into the cross-entries; the most of the air current goes over or under the curtain or passes it on either side.

The old workings are never examined, not even once a week. I have known cases where mines have not been examined after an idle day, and the men are allowed to go in and work as usual. On many haulage roads, water is allowed to flow down the middle of the track and where mules are used to haul the coal a miner, making a misstep, will go up to his knees in mud.

In conclusion, I wonder that any mine foreman or assistant foreman would neglect to perform his duty, under the good rules that are laid down for their benefit in West Virginia, regardless of the offer of a premium for so doing. While a word of encouragement goes far toward securing the faithful performance of duty, any neglect of duty should meet with a sufficient reprimand.

A. R. HAMFLETT.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

Caution—In the calculation of all problems in mine ventilation, regard must be had to th[illegible]s with respect to the power and the pressure [illegible] resulting from the circulatio[illegible] of the air in t[illegible]

Both the power and the pressure are commonly said to produce the circulation; but, as a matter of fact, it is the power that produces the circulation, while the pressure is the result and measured by the resistance of the mine or airway.

Unfortunately, these factors do not vary alike, but the cube root of the power varies as the square root of the pressure; or, more simply, the cube root of the power ratio, in any mine or airway, is equal to the square root of the pressure ratio.

$$\sqrt[3]{\frac{u_1}{u_2}} = \sqrt{\frac{p_1}{p_2}}$$

For example, in order to double the pressure ($p_2/p_1 = 2$)

$$\sqrt[3]{\text{power ratio}} = \sqrt{2} = 1.414$$

$$\text{power ratio} = 1.414^3 = 2.828$$

In other words, if 10 hp. on the air produces a given pressure or water gage in a certain mine or airway, it will require $2.828 \times 10 = 28.28$ hp. to double that pressure or gage.

Use of Potential Factors—Attention has been drawn to the potentiality of an airway or mine, in respect to the resistance it can offer to the passage of air, by virtue of its rubbing surface (s) and its sectional area (a). The potential of an airway or mine is the factor that determines the quantity of air such airway or mine will pass, for any given power or pressure. It is important, in the use of the potential, therefore, to consider whether the pressure or power is in question.

For every airway or mine, therefore, there is a power potential (X_u) and a pressure potential (X_p). The cube of the power potential is equal to the square of the pressure potential, for the same mine or airway, giving the equal values.

$$X_u^3 = X_p^2 = \frac{q^3}{u} = \frac{q^2}{p} = \frac{a^3}{k\,l\,o}$$

An inspection of these equal values shows that:

1. The quantity of air a given power will circulate varies as the power potential of the airway or mine.

2. The quantity of air a given pressure will circulate varies as the pressure potential of the airway or mine.

Hence, in comparing the circulations in different airways or mines, a constant power requires the use of the power potential, and a constant pressure, the pressure potential.

Other Potential Formulas—Transposing the values given above makes it possible to calculate the power or pressure required to circulate a given quantity of air in a certain airway or mine directly from its potential factor.

$$u = \left(\frac{q}{X_u}\right)^3 = \frac{q^3}{X_p^2}$$

$$p = \left(\frac{q}{X_p}\right)^2 = \frac{q^2}{X_u^3}$$

The Coal Age Pocket Book

It is, likewise, possible to calculate the quantity of air a given power or pressure will circulate against any given potential factor representing a certain airway or mine, by simply multiplying the cube root of the power or the square root of the pressure by the proper potential of the airway or mine as expressed by the following formulas:

$$q = X_u \sqrt[3]{u}$$

$$q = X_p \sqrt{p}$$

A few examples will serve to make the use of these formulas clear and to show their practical application, in the rapid estimation of what is required in the proposed development of mines, in order to make suitable provision for their proper ventilation.

EXAMPLES FOR PRACTICE

1. If 25 hp. produces a water gage of 1.5 in., in a certain mine, what water gage will 40 hp. produce in the same mine?

Solution—Since the square root of the pressure or water-gage ratio is equal to the cube root of the power ratio, calling the required water gage x,

$$\sqrt{\frac{x}{1.5}} = \sqrt[3]{\frac{40}{25}} = \sqrt[3]{\frac{8}{5}} = \sqrt[3]{1.6} = 1.17$$

$$\frac{x}{1.5} = 1.17^2 = 1.37, \textit{ nearly}$$

$$x = 1.5 \times 1.37 = 2.05 \textit{ in.}$$

2. It is proposed to provide for the circulation of 75,000 cu.ft. of air, in two generally equal splits, the airways including the return in each split being 6x10 ft. in section and about 8000 ft. long. (a) Find the power potential for the entire mine; and (b) calculate from that both the power and the water gage of the circulation.

Solution—(a) The sectional area of the airways, in this case, is $a = 6 \times 10 = 60$ sq.ft.; the total rubbing surface in the mine, $s = 2 \times 2\ (6 + 10)\ 8000 = 512{,}000$ sq.ft. Substituting these values and that for the coefficient of resistance $k = 0.00000002$ in the formula for power potential of mine,

$$X_u = \frac{2\,a}{\sqrt[3]{k\,s}} = \frac{2 \times 60}{\sqrt[3]{0.00000002 \times 512{,}000}} = 552.6$$

The power on the air required to circulate 75,000 cu.ft. of air against this potential is, then,

$$u = \left(\frac{q}{X_u}\right)^3 = \left(\frac{75{,}000}{552.6}\right)^3 = 2{,}500{,}000 \textit{ ft.-lb. per min.}$$

The water gage, as calculated directly from the power potential, $X_u = 552.6$, is

$$w.g. = \frac{q^2}{5.2\,X_u^3} = \frac{75{,}000^2}{5.2 \times 552.6^3} = 6.41 \textit{ in.}$$

Or, the water gage may be found thus

$$w.g. = 2{,}500{,}000 \div (5.2 \times 75{,}000) = 6.41 \textit{ in.}$$

Book Reviews

THIRTY-FOURTH ANNUAL REPORT OF THE DIRECTOR OF THE UNITED STATES GEOLOGICAL SURVEY to the Secretary of the Interior for the Fiscal Year Ended June 30, 1913. 172 pp. + index. 5¾x9⅛ in. 2 pl. 0 illus. Paper cover.

This report gives an outline of the work of the Geological Survey during the past year, a work which was somewhat hampered by a decrease in appropriation. However, as usual, a most creditable amount of work was effected. Already 38.9 per cent. of the whole area of the United States has been surveyed by this department of the Federal Government with the aid of state appropriations.

The allotment for coöperative work made by the State of Pennsylvania was only $5528.19, whereas West Virginia contributed $12,000, Ohio $25,000, and Washington $13,750. In fact, 11 states were more liberal contributors than Pennsylvania despite the importance of her mineral production.

The land classification board makes an extensive report leaving out, however, that particular table to which we made exception. Interesting tables are added, however, one showing a summary of coal-land classifications and valuations in force June 30, 1912 and 1913. The highest average price of coal lands is in Colorado, where the figure is $59, the lowest in South Dakota, where it is $11. These figures are interesting, but we must always remember that much coal land is listed at $10 and $20 which Mr. Ashley says is not worth that much, and some of which we may be sure is not worth a song. This decreases the average price by its inclusion as coal land.

SALES OF COAL LAND JUNE 30, 1912, TO JUNE 30, 1913

Per Acre Price	Acres	Per Acre Price	Acres	Per Acre Price	Acres
$10	5,328.80	$60	160.00	$120	81.68
19	22.80	65	40.00	130	163.19
20	2,897.86	70	40.00	135	56.96
25	120.00	80	40.00	150	22.33
30	40.00	85	40.00	155	80.08
35	40.00	100	194.81	175	16.21
40	40.00	110	198.73	200	77.06
45	80.00	115	63.19		
				Total	10,338.70

These figures were obtained by a comparison of the totals in the two most recent bulletins.

We trust, however, that the present intention of the administration will continue and we shall replace purchase by lease. If these lease rates are small they will not largely exceed the costs of supervision and the question of what to do with the income will not arise. The surveys which coal valuation have made necessary have been of immense value and extremely creditable to the Geological Survey. We hope they will be pushed just as vigorously when valuation ceases. In fact, the work will be even better when less hurried.

TESTS OF PERMISSIBLE EXPLOSIVES BULLETIN 66, BUREAU OF MINES. By Clarence Hall and Spencer P. Howell. 313 pp. 5⅞x9⅛ in. 1 pl. 6 illus. Paper cover.

The bulletin gives details of the results of the tests made on all explosives declared permissible between May 15, 1909 and Mar. 1, 1913; bulletin 15 giving an account of those explosives which were approved before the former date.

It is interesting to note how rapidly the consumption of short-flame explosives is increasing. In 1902, only 11,300 lb. were sold; in 1907 the sales had already risen to 2,095,244 lb. The formation of the Technologic Branch of the Geological Survey and the creation of the Bureau of Mines caused a rapid development in the use of these explosives, so that the sales in 1912 were 18,149,977 lb.

We have calculated the increase by percentages year by year since 1903, the increase of one year over the previous being set against the later year of the two: 1903, 2454.5 per cent.; 1904, 110.7 per cent.; 1905, 69.5 per cent.; 1906, 48.7 per cent.; 1907, 36.6 per cent.; 1908, 0.6 per cent.; 1909, 324.1 per cent.; 1910, 32.2 per cent.; 1911, 13.6 per cent.; 1912, 35.1 per cent.

This list does not give a clear conception perhaps of what the Bureau of Mines and its predecessor accomplished because the early increase represented only a small increment in output. A few mines served to make the difference recorded. But the really noteworthy part of the list is that for 1908 and 1909. In 1908 the Technologic Branch of the Geological Survey had been started but had done no really effectual work. Many still believed that coal dust could not be exploded by black blasting powder shots without the presence of gas. The sale of short-flame explosives was at a standstill and some were being discredited. Then suddenly the increase rose under the fostering care of the Technologic Branch of the Geological Survey from 0.6 per cent. to 324.1 per cent. and the increase in sales has been high ever since and we have now more reliable permissible explosives than perhaps any other nation.

The amount of permissible powder should in the opinion of the authors be multiplied by 2, if we would obtain the equivalent quantity of powder of equal economic effect. The monograph claims that the use of permissible powder does less harm to the roof and permits the placing of timber closer to the face. The impulse being more rapid the effect is localized on the coal.

New methods have been adopted in testing. Two tests have been dropped, it having been found that explosives passing the other tests never failed in these two and that therefore they were not necessary. But in order to test the cartridges more truly under working conditions, they are fired in their commercial wrappers and not in tin foil. The paper contains no oxygen and the whole charge is increased in carbon by its addition. As a result less complete combustion results, more carbon monoxide is formed and the heat of combustion and the consequent pressure is reduced. As the presence of coal around the shot and the dust in the hole increases the carbon, decreases the carbon dioxide and decreases temperature and the pressure, it is a pity that a way has not been found to test the pressure developed under working conditions, but we suppose that is asking too much. The suggestion is worth considering, however.

Further variation is found, due to the formation of hydrogen in the blasting holes in mines, as much as 6.8 per cent. being found. As this is probably formed by dissociation of water, it must have an immense cooling effect on the flame and would offset "any increase in the duration of the flame caused by the coal entering into the explosive reaction."

There is so[illegible] is of interest in this book that it is somewhat [illegible] review. We advise the reader to read it with care as [illegible] much credit to the authors and contains much that is new and valuable. Of course the bulk of the book is intended for reference and comparison only.

COMPRESSED-AIR PRACTICE—By Frank Richards. IX + 326 pp. 6x9 in. 96 illus. McGraw-Hill Book Co., Inc., 239 West 39th St., New York City. Cloth boards. Price, $3.

No one who reads "Compressed-Air Practice" will declare Mr. Richards commercial. In his conversational style he ends his preface with the remark "Catalog 'literature' and auctioneer talk have their place but not here" and the promise thus made is kept throughout the book, not we think entirely to the writer's interest. The book tells us nothing about the design of compressors. It is impossible to do this without illustrating some types on the market and Mr. Richards has therefore eschewed them all.

So after giving consideration to the thermo-dynamics of compression, theoretical and practical, he gives only the barest generalizations on the details of construction. Then he describes the turbo-compressor, the Taylor hydraulic compressor and the Humphrey pump. Two chapters follow on the power cost of compressed air and on power from that source; the air receiver and pipe friction are then treated and also the economy of reheating the air.

Compressor and receiver fires are discussed and side lines for the compressor are then treated at some length. Apparently the author is anxious to introduce compressed-gas distribution into our large cities instead of the present low pressure. Electric air drills, the air lift, the use of air in hammers, such as have hitherto utilized steam, diving bells and caissons, the air jet, sand blast and the cement gun all receive consideration and the book ends with an account of methods of liquefying air.

The inefficiency of the air receiver as a cooling and drying device is discussed and the author's argument is well sustained. The small area exposed to the cooling influences, the short time the air is in the receiver, the absence of impinging surfaces on which water can be deposited, all serve to make the receiver of little value for cooling or drying the air. For this reason compressed-air pipe lines are always fitted with large water traps.

Coal and Coke News

Washington, D. C.

Under the influence of the Wilson administration bills to regulate the development of government owned lands in Alaska have been prepared by the Chairman of the Public Lands Committees in both Houses of Congress in consultation with Secretary Lane of the Department of the Interior and will be pressed forward as rapidly as possible as companion pieces to the Alaska railroad legislation. They are designed to make available for immediate development treasures in coal, oil, phosphate and potash deposits.

Drafted along the lines recommended in Mr. Lane's annual report, the bills provide for the leasing of public lands under rigid restrictions to guard against monopoly and to insure full development.

The law to govern oil land leasing would provide that the Federal Government issue a permit for 2560 acres, which would give the possessor the exclusive right to explore for oil in this territory for a period of two years, during which time exploration work aggregating 2000 feet in depth must be done. If oil is discovered, the permittee would be entitled one-fourth of the land in fee, the remainder of the land to remain with the Government and be subject to lease in small tracts upon a royalty basis.

Under the proposed leases or patents granted no drilling of wells could take place within 200 feet of the outer boundaries of the lands leased or patented, and provision is made for general regulations requiring precautions to prevent waste of oil or the entrance of waters into the oil sands or oil-bearing strata. Forfeiture of the lease would be the penalty for violating these conditions and forfeiture could be effected through court procedure.

It is proposed that the coal lands of the country, which are all in great part classified, be sold at present, in small blocks, but provision would be made in the bills for leasing them, any holding not to exceed 2560 acres. It also would provide that for strictly local and domestic needs limited permits may be granted for tracts not to exceed ten acres for a period of ten years.

To insure against speculative holding, a small annual rental per acre will be charged. Similar provisions adapted to the different conditions are proposed as to the production of phosphate and potash.

* * *

After an unexpectedly long delay the Senate Committee which was charged with the duty of investigating conditions in the West Virginia coal strike region has filed a report without, however, making any definite recommendations. The recommendations are withheld because of the fact that, as stated, conditions are now quiet in the disturbed region while Congress in the original resolution of inquiry did not call for any specific suggestions. The report does not take as drastic a position as had been expected but among the "contributing causes" which led to trouble it mentions the following:

"The failure of the operators in the Paint Creek district to renew their expiring contract with the United Mine Workers; the determination of the coal operators under no circumstances to recognize the miners as an organization or union, and the equal determination of the miners to organize and form a union, a right as they claim guaranteed to them without discrimination by the laws of West Virginia; the employment by the operators of mine guards, many of whom were aggressive and arbitrary; mine guards in the employment of the operators acting as deputy sheriffs and clothed with the authority of the law; the failure of the civil authorities to attempt even to preserve peace and order at the beginning of violence and permitting things to drift from bad to worse without vigorous interference and assertion of authority; discontent among the miners occasioned by no opportunity to purchase homes, no cemeteries except upon the company's grounds; post offices located in the company's stores; private roads only to the schools and stores; the disposition of the coal operators to keep strict espionage of all strangers who entered the district and to exercise their right of private ownership of this large district and to exclude from it all persons objectionable to them. These may be stated as some of the immediate contributing causes."

Harrisburg, Penn.

The operating cost in taking a ton of anthracite coal from the Schuylkill district to Philadelphia is 44.698 cents per gross ton on the Philadelphia and Reading R.R., while transporting a ton on the Pennsylvania from the Schuylkill, Lehigh and Wyoming Regions costs from 49.816 to 77.42 cents.

These figures are found in the report of Price, Waterhouse & Co., expert accountants who have been investigating the transportation charges on coal shipments from the anthracite region to Philadelphia for the Public Service Commission. The report was made public on March 6, by the commission, which has fixed March 30 as the day when argument will be heard on the rate inquiry at Philadelphia.

Incidentally, it is interesting to note in connection with the report that the freight rates of the various railroad companies per ton of coal from the anthracite region to tidewater at Philadelphia are as follows:

"From the entire Schuylkill region over the Reading or Pennsylvania lines to Philadelphia $1.70 per gross ton.

"From the Lehigh region in connection with the Reading or Central R.R. of New Jersey, via Allentown, $1.86 to Philadelphia; over the Lehigh Valley R.R. via East Penn Junction, $1.86; to Germantown, either route, $1.96; to Chestnut Hill, either route $2.06.

"From the Lehigh region, over the Lehigh Valley or Central R.R., via Pennsylvania R.R. connecting at East Philadelphia Junction $1.80.

"From the Wyoming region, Central R.R. or Lehigh Valley, over the Reading $2.10; over the Pennsylvania, via East Phillipsburg Junction $1.80."

To establish an adequate basis for the determination of the cost of transportation the accounts for the twelve months ending May 31, 1913, were examined, and the estimate of cost includes expenditures for (1) operating expenses, (2) taxes, (3) hire of equipment and (4) miscellaneous. The inquiry of the accountants, however, has been restricted to the question of operating costs and taxes, and they have not dwelt in any way with the question of investment and return thereon, a highly important factor.

In case of the Philadelphia and Reading, the records of revenues by divisions are not maintained, but in the case of the Pennsylvania it appears in the aggregate the revenue of the divisions involved in the anthracite coal traffic amounted for the year under consideration, to $73,917,654, and the operating expenses amounted to 71.25 per cent. of the revenues, leaving 28.75 per cent. to provide for return on investment and for any reserves for extraordinary purposes. While there are no figures as to the value of the investment now available, it seems probable that such a percentage would not be greatly in excess of a fair return.

"In the case of the two railroads in question (Philadelphia & Reading and the Pennsylvania), a considerable proportion of the subdivision of the expenses between passenger service and freight service was readily obtainable from the books in proper form. In some particulars, however, we have had to take exception to the methods of subdivision, and, in the case of the Philadelphia & Reading R.R., the subdivision is not fully carried out by the company and had to be completed by ourselves. The subdivision of the cost of freight service among merchandise, anthracite, bituminous coal and coke was for both companies carried out in the main by ourselves on the basis of data secured from the records. So far as we have been able to ascertain, neither company determines the cost of the anthracite traffic separately from the freight traffic, but each secures concurrently a considerable amount of pertinent information."

The report says that the terminal cost of anthracite traffic is relatively low, by reason of its being handled in bulk and usually with mechanical aid. On the other hand the value of the property employed in its terminal handling is an important item and calls for due consideration in the determination of the fair return that the traffic may be expected to yield.

The report states that the whole problem of determination of costs for rate purposes is still in an early stage of development.

PENNSYLVANIA

Anthracite

Scranton—A demurrer to the action in equity brought by the People's Coal Co., of this city, to test the constitutionality of the anthracite coal tax act of 1913, was filed by the Attorney General's Department on March 9, in behalf of Auditor General Powell and State Treasurer Young, the accounting officers of the Commonwealth. No steps for the collection of the tax have been taken by the State since the suit was brought, although all the reports are stated to be in hand and the bill can be sent out. The demurrer declares that the Dauphin County court, wherein the suit was brought is without jurisdiction to entertain the bill of complaint; that the bill does not state any facts, entitling it to belief; that the bill contains "many wholly irrelevant, immaterial, scandalous and impertinent matters and does not show on its face that the plaintiff is entitled to any relief which it seeks" that nothing is shown entitling the plaintiff to a permanent injunction; that the bill does not show the act to be unconstitutional in any respect. Date for argument will be fixed later on.

Hazleton—In the last year four companies in the 11th anthracite district did not have any fatal accidents at their collieries. They were Coxe Bros. & Co., Inc., Pardee Bros. & Co., the Harwood Coal Co., and the Upper Lehigh Coal Co.

According to the annual report of David J. Roderick, the mine inspector, there was one death for every 293,788 tons of coal mined, against one for every 275,000 tons the previous year. The inspector is gratified over the reduction in fatalities, and points to this record as one of the signs that more preventive measures are being taken.

Bituminous

Shenandoah—The Buck Mountain vein of 15 ft. of fine coal was struck on Mar. 5, by Dolan Bros., tunnel contractors for the Locust Mountain Coal Co. The company will begin shipments as soon as the new breaker, in course of construction is completed. The unexpected strike completes the tunnel and saves thousands of dollars for the company.

Harrisburg—The Public Service Commission has recommended that an evening service between Pine Grove and Outwood be installed for the accommodation of the miners residing along the S. & S. branch of the Reading R.R. The schedule calls for a train that will reach Outwood not later than 6 o'clock p.m. This service will take the miners home directly from the mines and they will no longer be compelled to walk several miles. The Commission found that it would not be reasonable to order a morning service from Outwood, because it would involve a net loss of $25 daily to the Reading Co.

West Pittston—Members of the Continental local of the United Mine Workers have made an investigation of conditions in the territory covered by its activities, and have discovered much acute poverty among the people. This report was made at a meeting of the local, and it was decided to empty the treasury of the local to alleviate the distress. There is about $4000 in the treasury and this money will be expended in keeping the families of the men who are in need, as well as in taking care of those who are outside the organization. The members of the Continental local have not been employed for some time. The mine has been shut down for repairs, the closing down following the announced presentation of some grievances on the part of the workers.

KENTUCKY

Frankfort—The Kentucky Railroad Commission has entered an order in the case of the Paducah Light & Power Co. against the Illinois Central Railroad Co. reducing rates of coal from the western Kentucky field to Paducah from 80 to 60c., and requiring restitution of $1,729.98 for overcharges made on coal from that section by the railroad.

Owensboro—It is understood that the Fern Hill mine, near this city, has been sold to the Deep Water Coal & Coke Co., of Evansville, Ind., which has been acquiring various coal properties in this section during the past two months, for $87,000.

Louisville—The scale committee of the United Mine Workers of America, District No. 23, was in session here all this week, formulating the wage scale which will be presented to the operators in the union (western Kentucky) section of the Kentucky field shortly as a basis for negotiations. The committee's deliberations were attended by about sixty delegates from the field. L. B. Walker, of Central City, Ky., presided. The wages scale to be adjusted will cover the next two years.

TENNESSEE

Jacksboro—After a year of prospecting the Lindsay Coal Co., of which H. B. Lindsay is president, operating near Caryville, Tenn., struck a fine vein of coal 4 ft. thick. The vein was struck after penetrating the mountain 1600 ft. with a 12-ft. entry. The company will at once enlarge its equipment and operate the vein on a large scale.

Knoxville—The executive committee of the Southern Appalachian Coal Operators' Association met at its rooms last week, reëlecting J. E. McCoy as Secretary, and discussing a number of matters of importance, including the rate adjustment covering the section, which is now pending before the Interstate Commerce Commission. The committee was composed of President E. C. Mahan, James R. Wooldridge, T. I. Stephenson, Alexander Bonneyman, N. B. Kenney, H. L. Cory, L. I. Coleman, L. I. Coleman, W. C. Tucker, H. S. Pless and A. H. Wood.

ILLINOIS

Marion—The new washer of the Peabody Coal Co. at mine No. 3 is now in operation and is the latest and most uptodate washing plant in the state, and at the same time is considered the most economical. It makes only three sizes of washed coal, No. 1 and No. 2 nut, and washed screenings.

Perry County—This county is at present the scene of a good deal of activity on the part of St. Louis capitalists, who already have secured options on 5000 acres of virgin coal lands in that section, and are seeking leases on 15,000 more. Joseph Crawford, President of the Murphy-Wall Bank & Trust Co., of Pinckneyville, Ill., represented the St. Louis men in the deal. Prospecting for coal will begin as soon as the options on 20,000 acres have been secured. Prospectors also have optioned a tract of coal land north of Pinckneyville. All of the area referred to is in proximity to the proposed electric road between Springfield and Duquoin, which will provide an outlet for mine products.

Belleville—R. W. Ropiequet, who was primarily the organizer of the 5th and 9th District Operators' Association, and who has been prominent in the affairs of the operators in the 5th and 9th districts for the past four years, has resigned and in the future will have nothing more to do with that organization. Mr. Ropiequet has done more for his organization than has been accomplished for a similar body anywhere in the United States by any one individual. He compelled the Illinois Central Railroad to build several thousand coal cars for the mines in his district on that road, and, in losing him, the coal trade will miss one of its most valued and competent men.

INDIANA

Evansville—Manager Henry F. Allen, of the Deep Water Coal & Coke Co., which recently took over a number of mines in the Western Kentucky district, announced recently that the company's policy would be to operate its mines with union labor exclusively. This announcement has been received with much enthusiasm by labor leaders, who are attempting to strengthen their organization in Western Kentucky.

KANSAS

Topeka—The Kansas Public Utilities Commission will hold another meeting in March for the purpose of hearing additional evidence in the mine-run case which has been pending for the past few months. The hearing will be held about Mar. 14, and is expected to result in some decision in the case.

Leavenworth—Fire originating in the tipple of the Home mine of the Home Riverside Coal Mining Co., destroyed the buildings with a loss of $25,000. Men working in the mine escaped through the Riverside shaft, two miles away. Three hundred and fifty miners were employed and will be out of work pending the rebuilding of the tipple and other structures included in the loss. About two-thirds of the loss was covered by insurance. The burning timbers dropping into the mine did not set fire to the buntings and the mine itself was uninjured. Twenty mules were driven underground two miles to the Riverside shaft and saved. A pump was installed and a temporary hoist operated, in order to keep the shaft clear of water. The Home is the oldest mine now operated at Leavenworth.

MISSOURI

Webb City—Missouri State Mine Inspector, George Hill, recently instructed deputies in the Southern district to enforce rigid observance of the eight-hour law. Communications to this effect from Mr. Hill were read at the meeting of district inspectors.

MISSOURI

Kansas City—Four coal company members of the Southwestern Interstate Coal Operators' Association have filed suit against President Chas. F. Keith of the Association, for alleged unwarranted payments amounting to not less than $40,000. Referring to certain funds of the Association the complaint states: "That the Association received no consideration therefor nor benefit therefrom; that they were foreign to the Association purposes and wholly unauthorized by it." The four companies involved in the procedure comprise the Bache-Denman interests and are the Prairie Creek Coal Mining Co., the Mammoth Vein Coal Co., the Coronado Coal Co., and the Kali-Inla Coal Co. Mr. Keith is president of the Central Coal & Coke Co.

Kansas City—The joint meeting of a committee of operators and miners held at the quarters of the Southwestern Interstate Coal Operators' Association in the Keith and Perry building on March 4 and 5, failed to result in an agreement on disputed points of the Kansas workmen's compensation law, passed in 1913. A resolution was adopted, recommending the appointment of an arbitration committee, to act as provided in Section 24 of the compensation law. This committee, should it at any time be unable to agree on the interpretation of any clause in the law, shall have the power to appoint one man as referee, and his decision shall be final. The arbitration committee is to be composed of an equal number of miners and operators. State Labor Commissioner, William L. O'Brien, of Kansas, attended the hearings in Kansas City, as did representatives of the operators and of employees. It was finally decided, after the meeting had gone two days, that the committee would ask the operators to reach some definite interpretation of the law and present it to the committee. Another meeting of operators and miners will be held in Kansas City later in the month. The mooted points were chiefly, when shall payment in case of injury to a miner begin; shall compensation be based on the gross or net earnings of the miner, and what does "concurrent employment" mean?

COLORADO

Denver—The Federal Strike Investigating Committee have secured a sworn statement from Arthur Langowski, 21 years old, to the effect that he receives $3 a day from the coal operators while exploding dynamite for the United Mine Workers of America. When questioned by the committee, he denied being a spy in the ranks of the union, although he admitted that he was "watching both sides" and received pay from both.

A compulsory arbitration law for the settlement of disputes between coal operators and their employees, is one of the recommendations of the committee. This proposal is fathered by Representative Howard Sutherland, of West Virginia, who takes the position that coal is a public necessity. It is possible that the enactment may lead to a Federal statute similar to the Canadian "Dispute Act," which includes coal-mining industries in which controversies between labor and capital must be submitted to boards of mediation.

WASHINGTON

Olympia—A statistical report of coal operations in the state of Washington during the past year has been compiled by James Bagley, state inspector of coal mines. The report shows that 3,823,837 short tons were produced, as compared with 3,346,946 during the year 1912, an increase of 476,901 short tons. An increase of 26,843 tons of coke was also indicated, 75,732 tons being produced as against 48,889 in 1912. The report shows also that the total number of men employed in the mines during 1913 was 6065, as compared with 5673 employed during 1912, an increase of 392 men.

CANADA

Montreal—According to the preliminary report on the mineral production of Canada during 1913, prepared by John McLeish, chief of the Division of Mineral Resources and Statistics, of the Department of Mines, and presented at the 16th annual convention of the Canadian Mining Institute, recently in session at Montreal, the total value of the output was $144,031,047, as compared with $135,048,296 in 1912. The production of coal was 15,115,089 tons, as against 14,512,829 tons in 1912; the year being marked by an increased production in Nova Scotia, New Brunswick and Alberta, and a diminution in the output of Saskatchewan and British Columbia. The decrease in the latter province amounted to almost one-half million tons and was due largely to the continuance of the strike in the Vancouver Island mines.

The total output of oven coke in 1913 was 1,517,133 tons, made from 2,147,913 tons of coal, of which 1,598,912 tons were mined in Canada; 549,001 tons imported.

PERSONALS

V. S. Veazey has recently been appointed Chief Engineer of the McVell Coal & Coke Co., of Glen Jean, W. Va.

George P. Wilson, of Philadelphia has been appointed chief of the bureau of tariffs by the Public Service Commission, the appointment to date from March 16.

George A. Gallinger, of Pittsburgh, has been placed in charge of the Pneumatic Tool Department of the Ingersoll-Rand Co., with the title of Manager of Pneumatic Tool Sales. His headquarters will be at 11 Broadway, New York City.

Joseph Huddleston, a coal operator of Excelsior, W. Va., and Mrs. Georgia C. Bayman, of Huntington, W. Va., were married last week in Jeffersonville, Ind. Mr. Huddleston is a prominent figure in the field where his mines are located.

Irving R. Gard, late mining engineer for the Canadian Collieries (Dunsmuir), Ltd., of Victoria, B. C., Canada, has been placed in charge of the properties of the Mecca Colliery Co., with headquarters at Eagle, W. Va. Mr. Gard assumed his duties Feb. 15.

K. U. Meguire, of Louisville, Ky., President of the Harlan Coal Mining Co. and of the Snead & Meguire Coal Co., left recently for a vacation trip to Florida, where he will recuperate from his labors on the workmen's compensation bill, which is before the legislature.

Sheffield Ingalls, Lieutenant-Governor of Kansas, allowed his option on a mine near Atchison, Kan., to expire on Feb. 15, and the plant probably will be purchased by a power company. W. B. Collett is representing the latter in new negotiations. Gov. Ingalls was unable to interest capital in the mine.

F. M. Sackett, of the North Jellico Coal Co., an operating concern, and of the Byrne & Speed Coal Co., of Louisville, is the chairman of a committee which is working to secure the donation for the erection of a public auditorium with the refunds of excess rates being made by a local telephone company to its subscribers, and is meeting with considerable success in the campaign.

OBITUARY

A. H. Reeder, president of the Stonega Coal & Coke Co., of Stonega, Va., died in Philadelphia a few days ago following an operation for blood-poisoning, which was due to frost-bite suffered while hunting. Mr. Reeder was well known in the coal fields of Western Virginia and Eastern Kentucky

Edward Wells, aged 82, president of the Hollenback Coal Co., died on Mar. 8, at his residence in Wilkes-Barre, Penn. He was a director in a number of Eastern banks, and a trustee of the Wyoming Historical and Geological Society. Mr. Wells is survived by his wife, one son, and his brother, John Wells Hollenback, a prominent coal-land owner.

John Yoeman Boyd, one of the most prominent coal men of the State of Pennsylvania and a member of the first Railroad Commission of Pennsylvania, died of heart trouble, on March 9, at his city residence, in Harrisburg, Penn. He was in his 52nd year. Surviving Mr. Boyd are his wife and four children.

Mr. Boyd was born in Danville, Penn., Aug. 9, 1862. He was prepared for college at the Harrisburg Academy and then entered Princeton. Since graduation he had been identified with the large Boyd coal interests and was heavily interested in Southern states. Mr. Boyd having succeeded his father who was a member of the noted Conyngham, Stickney & Boyd coal firm, of Philadelphia.

When the Railroad Commission of Pennsylvania was created, Edwin S. Stuart, then Governor, selected Mr. Boyd as a personal appointment, desiring one who was accustomed to large business matters. He was reappointed, but resigned because of the press of personal affairs, the management of his father's estate having fallen largely upon him. His resignation was the occasion of a tribute by Governor Stuart to his service in behalf of the State and of formal action by the other commissioners.

CONSTRUCTION NEWS

Kansas City, Mo.—The Central Coke & Coal Co., of this city, will install in its colliery at Rock Springs, Wyo., one 50-hp. and two 150-hp. motors and control equipments which have been ordered from the General Electric Co.

Lorain, Ohio—The announcement is made that the work of erecting the new unloading machine at the B. & O. docks, Lorain, will not be started until fall. When completed the machine will be one of the fastest on the Great Lakes.

Scranton, Penn.—The Hudson Coal Co., of this place, will install in its power station a 435 kv-a. motor-generator set and switchboard, and will place in operation in the mines three 7-ton, 30-in. gauge electric mining locomotives, which equipment has been purchased from the General Electric Co.

McAlester, Okla.—About $1,000,000 is to be spent here in the immediate future by the Rock Island R.R., according to a recent announcement. Much of this will go toward improving the mines now operated by the company, while two new operations are to be sunk on recently acquired coal lands. The number of miners to be employed will be increased largely.

Hazard, Ky.—The Kentucky-Jewel Coal Co. here have completed a first-class coal-mining plant three miles below here on the Lexington & Eastern R.R. and are now shipping 40 cars per day. The company announces a number of increases by Apr. 1. One hundred and fifty miners' houses are nearing completion. The coal field around Hazard is attracting much attention.

Wellsburg, W. Va.—Work has been started on the construction of ten new double blocks of houses at the La Belle Mine of the West Virginia Pittsburgh Coal Co. The United Mine Workers called a strike at this mine in November, and the influx of non-union miners since that date has been so great that the company was compelled to build new houses to accommodate them.

Pittsburgh, Penn.—The Pennsylvania Coal Co. of this city, will place in operation in substations considerable new electrical apparatus comprising one 500-kw., one 300-kw. and two 200-kw. two-unit three-bearing motor-generator sets; three 50-kv-a. and nine 100-kv-a. transformers; one 150-hp. and three 300-hp. motors; three control equipments, switchboards and accessories. The contract for all the apparatus has been placed with the General Electric Co.

McAlester, Okla. — Improvements contemplated by the Rock Island R.R. in this field in the near future include two new shafts and two additional slopes. One of the new shafts will be between Hartshorne and Gowen, 650 feet deep. The other will pierce to a depth of 800 feet, being at Alderson. Both slopes will be near Hartshorne. Mine No. 8 at Hartshorne probably will be abandoned. It has been sealed up for the past month, because of a recent fire. About 1500 new miners will be employed because of the additional capacity. This is expected to be in the neighborhood of 6000 tons daily. All of the new shafts will be equipped with steel tipples, late screening devices and other approved equipment. It is said that the Rock Island will utilize all of the facilities required by law, and will adopt the "safety first" idea extensively. Many of the old mines have been only partly equipped with modern casualty-prevention machinery, because of the difficulty of the task. The mines just being sunk, however, will embody all approved plans for "safety first."

INDUSTRIAL NEWS

St. Clairsville, Ohio—The Hutchinson Coal Co. has filed a mortgage of $1,000,000 with the Security Trust company, of Wheeling, W. Va., to secure a loan on coal properties in Belmont County, Ohio and Mason and Harrison Counties, W. Va.

Scranton—The Continental Miners Local of the U. M. W. of A., has voted $4000 from its treasury to aid members of the local who have lost their mine tools in the settling at that colliery. The men are unable to obtain work elsewhere because of their lack of tools.

Easton, Penn.—One of the largest mortgages filed at Easton for some years was that of the Lehigh Coal & Navigation Co., for $40,000,000. It is a consolidated sinking-fund mortgage, the principal of which is due on Jan. 1, 1954. The Pennsylvania Co. for Insurance on Lives and the Granting of Annuities is trustee for the bondholders.

Columbus, Ohio—At the annual meeting of the stockholders of the Ralston Steel Car Co., of Columbus, J. E. Tesseyman resigned as vice-president and general manager, being succeeded by Anton Becker. Other officers were reëlected. The company manufacturers steel cars for coal carrying and has had a very prosperous year.

Williamstown, Penn.—Property on which the Summit Branch Coal Mining Co., Lykens Valley Coal Mining Co., Northern Central Railways Co., and Isaac D. West were tenants, was sold on March 5 by the sheriff of Dauphin County to the Susquehanna Coal Co., for $2600. There were mortgages amounting to $220,364.25 against the property.

Wilburton, Okla.—The Great Western Coal Co of this place has been placed in the hands of a receiver. James Elliott, president of the Hailry Ola Mining Co., was made receiver. The company, capitalized at $200,000, is said to be in fairly good shape, despite the receivership, and is expected to resume operations in the near future. About 200 men are employed.

Sharon, Penn.—The Carnegie Steel Co. reports successful results of the experiments they have been conducting with pulverized coal in an openhearth furnace. With this new fuel, the quality of the metal was not only higher, but more heat was secured in much less time than required by the old method. At present, the Carnegie Co. have only one such furnace in operation, but they have signified their intention of erecting others immediately.

Spadra, Ark.—The Clark-McWilliams Coal Co., of this place, has purchased all of the holdings of the Southwestern Anthracite Mining Co., of Scranton, Penn., at Hartman, Ark. Included in the deal is 386 acres of coal lands, in John County, estimated to hold 2,000,000 tons of coal. The purchase price was not announced. The Clark-McWilliams Coal Co. will erect a $50,000 plant, with a 500-ton daily capacity, in the immediate future. The deal is the largest consummated in Arkansas during the past few years.

Zanesville, Ohio—Because of lack of orders and uncertainties of the new mine-run law a number of mines in the Zanesville and Cambridge districts of Ohio have closed down permanently. The granger mine of the Pan-American coal company located at Buckeye, south of Zanesville, was closed down and the new mine to be opened by the company on Turkey Run will be abandoned for the time being. The Peabody mine at Shawnee; the Jones Mine at Corning and Mine No. 24 at Jacksonville were also closed down. The closing of these mines threw out of work about 2500 miners.

NEW INCORPORATIONS

Melbourne, Ill.—The Melbourne Coal Mining Co. has been incorporated here, capital $3000, by B. S. Moulton, A. L. Chambers and Louis M. Davis.

Pittsburg, Kan.—The Interstate Operators' Coal Co. has filed articles of incorporation here. The capitalization is placed at $10,000. The company proposes to enter the coal mining field.

Fayette, Mo.—The Howard County Coal Co., capital $4000, has been incorporated here, with C. W. Watts, President, and Frank Grimes, Secretary. They have purchased and will develop the Russell property.

Brilliant, Ohio—The Blyth Coal Co. has been incorporated with a capital of $25,000 to mine and deal in coal. The incorporators are F. H. Bruening, F. T. Fitzharris, A. E. Vance, W. McD. Miller and J. S. O'Neil.

Lexington, Ky.—The McCormick Lumber Co., with a capital stock of $75,000, has filed articles of incorporation, under which it is authorized to develop coal, coke and timber lands in Kentucky. The company owns several valuable tracts of coal lands in Powell county, which are traversed by the Louisville & Nashville's L. & E. branch. It proposes to cut the timber on these tracts, and then develo the coal.

Coal Trade Reviews

General Review

Trade rounds out the season in better form than anticipated. Colder weather and delays in transportation create some activity. Little preparation being made for a suspension.

With the spring discount on anthracite now only two weeks off the trade is relapsing into the customary lethargy at this period. But as a result of the persistently cold weather over the past few weeks the market is rounding out the winter season in better form than was anticipated, and considerably better than in average years. Stocks in the hands of the dealers are being so rapidly exhausted that many of them are being forced into the market for small tonnages to tide them over. But all such orders are restricted to the lowest possible minimum, and new business is scarce. A gradual slowing down, with individual prices touching the April circular, will probably be the record over the balance of the month. Judging from the business now being negotiated there will be considerable activity at the opening prices, Apr. 1.

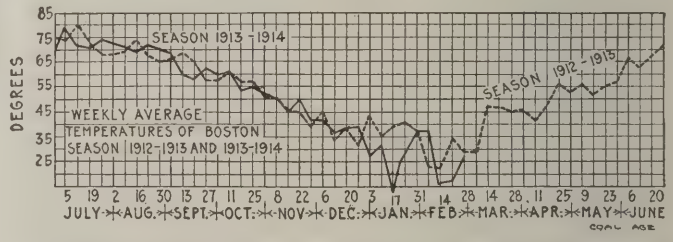
The continued low temperatures have had a mildly stimulating effect upon bituminous trade, but the business is still characterized by an almost total lack of interest on the part of buyers. The market has failed utterly to respond to the possibility of a protracted suspension in the mining regions. Concessions are readily obtainable on spot business, although many contracts are being closed at last year's prices. The situation in the Pittsburgh district is decidedly stronger, but not so much as would be expected, as a result of the recent severe weather and the proximity of what may be a protracted suspension. It is generally hoped there will be a suspension of sufficient duration to clean up the surpluses in the market, and inject some snap into the trade.

Stocks in Ohio have been well cleaned up by the colder weather, and the trade is much improved under the influence of better orders for both domestic and steam grades. The market is in a waiting attitude, because of the uncertainty in the labor situation, and a turn for the worst in this direction will undoubtedly cause a sharp rush for coal. There is said to be less coal on hand now than at any time during the winter. Spot demand at Hampden Roads has shown some slight improvement, especially as regards inland business, but dumping over the piers continues light; considerable accumulations in the local yards are also reported, but much of this tonnage is being assembled to take care of a number of Government collieries.

The Middle Western trade is showing a stronger inclination to prepare for trouble after Apr. 1. While many of the larger consumers are still skeptical about any serious shortage, because of previous experiences, as a rule they are accumulating extra supplies. As a result of this, and the continued lower temperatures, a great many mines are working up to the full limit of the car supply, and it is clear that the Middle Western trade will round out the season in much better shape than had been anticipated.

EASTERN MARKET

BOSTON



Practically no change in Pocahontas and New River. Agencies very watchful of one another. Little interest in Pennsylvania grades, contracts being gradually closed along usual lines. Georges Creek shows usual steadiness. Anthracite dull for March loading, but with active business in prospect.

Bituminous—The contract situation on Pocahontas and New River mulls along with no pronounced features. The various agencies are watching one another closely and while some low prices are known to have been made they are so well covered up by water freight arrangements that it would be difficult to check them back.

Spot coal is practically unchanged. Concessions continue to be made and contractors are generally dilatory in arranging for March quotas. Stocks are seasonably large and practically none of the sizable consumers will show any interest in the market at anything like the $2.85 basis. The heavy curtailment is still on, but most of the shippers are not slacking up any in their efforts to place current output.

Little interest is apparent in the Pennsylvania coals just now. The threatened suspension in mining is arousing only the mildest kind of attention. Some of the operators have now come out with flat prices and contracts are being closed much along the usual lines, each aiming to hold the tonnage acquired last year. Some light will be thrown on the general status when the Boston Elevated Ry. makes known its decision on its supply for the next season. This is one of the large orders in this territory and the award is usually significant. Practically every coal house of any size has submitted figures and there is much speculation over the result.

It is understood that the Georges Creek factors have closed about their usual tonnage on the basis of $2.85 f.o.b. Baltimore. For two years at least this grade has shown great steadiness, due both to its popularity among certain trade and to a rather limited output.

Anthracite—The recent spring-like weather has caused the retail demand to sag off. Stocks are light, however, in anticipation of lower-priced shipments early in April and there is likely to be some anxiety among retail dealers until they receive their first round of deliveries; many of them have been sailing too close to the wind. The storm early last week in New York and Pennsylvania was practically without result in New England. The prospect is excellent for a heavy demand for April, May and June. The disposition here is to take anthracite in as large a volume as storage will permit.

There has been a rumor about a possible advance of 25c. in the price of stove in the effort to shift some of the demand to other less popular sizes.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.90	2.92@3.02	
New York*	2.50@3.05	2.80@3.20	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.75@2.85
Boston†				3.78@3.83
Providence†				3.73@3.78

*F.o.b. †On cars.

NEW YORK

Operations much curtailed by heavy storms of last week. Bituminous trade fails to respond to the strike talk. Loading in the harbor much delayed by frozen coal.

Bituminous—A persistent period of moderately low temperatures has served to clean up much of the surplus coal in the local market. Consumption has been increased, and as a result there has been a large hole made in the stocks on hand. On the other hand, the large shipments, delayed by the heavy storm of last week, are now coming in and tending to flood the market.

Transportation conditions are, however, not as free as might be expected. The Pennsylvania R.R. was the first to start coal moving again, and the situation on its lines is now relatively good. On the B. & O., the Reading, and others there is still considerable congestion. Early this week another storm in Pennsylvania again tied up the roads temporarily, distribution on the railroad being reported at only 80%. The general embargo at South Amboy has been removed, but boats are scarce and the loading continues slow, due to the frozen coal.

The local market is failing utterly to respond in any way to the possibility of a suspension in the mining regions. Some contracting is reported at prices said to be on the same basis as last year or better. The spot market is not quotably changed, and we continue it as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.75@2.80; best Miller Pennsylvania, $3.10@3.15; George's Creek, $3.15@3.25.

Anthracite—With the April discount now only two weeks off, dealers are cutting orders to the lowest possible minimum, in order to carry over as small stocks as possible. The persistent cold weather, however, has stimulated quite a little buying and will serve to wind up the season's business in hard coal in much better form than was anticipated.

Operations in the mining districts have been automatically restricted by the heavy storm, so that last week practically nothing was done until Thursday, while few mines succeeded in getting tuned up to full capacity before Saturday. Full capacity operations was the rule this week.

The demand continues to center around the steam grades. Most of the domestic sizes are still rather heavy. With boats scarce and difficult to load because of the coal being frozen, substantial premiums for loaded cargoes of the steam grades, including pea, were offered early in the week, as much as 30 to 40c. above the circular being readily obtained. Egg is the strongest of the prepared grades, with nut in fair demand, and stove heavy, selling off to the full April circular; April prices will probably prevail on all the prepared grades by Mar. 20, due partially to the fact that the line business is falling off heavily and excess tonnages are being dumped into the tidewater market.

We quote the New York market on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00		$5.05	
Egg	5.25	$4.95@5.35	5.30	$4.90@5.30
Stove	5.25	5.15@5.35	5.30	5.10@5.30
Chestnut	5.50	5.55	5.55	5.35@5.55
Pea	3.50	3.55@3.80	3.50	3.50@3.75
Buckwheat	2.75	2.75@2.90	2.70@3.45	2.45@2.90
Rice	2.25	2.25@2.40	1.95@2.20	1.95@2.30
Barley	1.75	1.75@1.85	1.70	1.60@1.80

PHILADELPHIA

Anthracite trade rather quiet in anticipation of opening prices. Prospects favorable for good spring business. Bituminous in better demand, but prices unchanged.

Anthracite—From now on until the first of April, the anthracite busines is not likely to be very heavy. It is true that quite a number of householders, whose bins were depleted by the recent cold weather, have found it necessary to purchase additional supplies, but as a rule, buying at this time means only piecing out for the remainder of the season. All the dealers are holding up their orders and conserving what coal they have, until the first of April when the opening prices become effective. It is understood that the new circular prices will be no different from last year, with the exception that the contract sizes will in all cases carry the Pennsylvania State tax.

As indicated by the business that is now being placed for delivery as soon as the opening prices are announced, there is likely to be a shortage in stove coal almost as soon as the market opens for the year's business. As a matter of fact, it is believed that most of the companies have stocks of most every size but stove, which has moved off uniformly throughout the year. There is likely to be little or none of this size carried over, but the dealers claim to be well supplied with egg and chestnut, and it is not a question of waiting until Apr. 1 for additional supplies, as concessions down to the April circular can already be secured from individual operators on these two sizes. Stove coal is likely to be the stumbling block for prompt shipments, and orders for this size are being accepted only on condition that a certain proportion of egg and chestnut accompany them. Broken coal is about the only size that is short in the market at present, and this is only a continuance of a condition that has prevailed throughout the past season. Tidewater business has fallen off entirely. Any orders now being placed as a rule call for sizes that are not likely to be effected by the usual spring discount.

Bituminous—There seems to be a slightly better tone to the market on bituminous coal. This is more particularly due to a better demand, rather than to advancing prices. The call seems to be more active, and may be due in part to the heavy weather of the last three weeks, not only retarding production, but interfering with railroad movement. As a matter of fact, operators are assuming a more optimistic attitude, and are looking forward to a better spring and summer business.

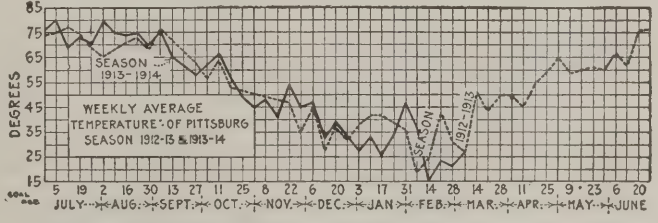
BALTIMORE

Shipments interrupted, communication cut off by wire, and other delays due to heavy storms. Upward price tendency was confined to individual cases of necessity. Anthracite men busy.

Heavy snowfall and blizzard weather conditions of last week generally played havoc with regularity of tonnage movement. For several days the mines were shut off from supplies of empties even after the railroads had reëstablished operations and were moving out loaded cars. The roads kept promising as rapid dispatch as possible, but the movement of empties toward mine centers was slow.

The result of interruptions to shipments on contract forced some consumers into the open market who are seldom seen there. For the most part mine connections here were able to supply coal to customers from other sources, but some had to dig outside. There was no excessive charging even on the emergency business, however, as there was plenty of fuel close at hand to meet to all needs. The upward tendency of prices was confined to this emergency call.

There was not quite as much activity to be noted about the piers, as delayed shipments, frozen coals, etc., had an effect. A number of important loadings are scheduled, however, for the rest of the month, and March will show quite healthy figures for both the foreign and coastwise movement. During February a total of 59,756 tons of coal was loaded here for foreign ports, this being a slight decrease from the February figures of 1913.



The several snow storms taxed the anthracite dealers here to the full, but the heavy orders on household account were gladly received.

CENTRAL STATES

PITTSBURGH, PENN.

Prices stiffer, but less improved than would be expected. Every prospect of mining suspension Apr. 1. Some stocking of coal by consumers. No important wage-scale developments. Connellsville coke market slightly easier but not quotably lower.

Bituminous—There has been a slight hardening in coal prices in the past week, so that circular prices are more generally obtained, but there is still some shading. The market is decidedly stronger than it was a fortnight ago, but it is not as much stronger as would be expected on general principles, seeing that the weather has been extremely cold and windy throughout the consuming districts, and it has become practically settled that there will be no wage agreement by Apr. 1. There is considerable stocking of coal, particularly by the railroads, but mine operations have not been increased materially, if at all, and are still not over 50 or 60% of capacity of an average. There have been no important developments in the wage-scale matter since the failure of the subcommittee of the Philadelphia conference to reach an agreement on any of the important points at issue. Circular prices remain: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.05; 1¼ in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The coke market has eased off a trifle in general tone in the past week, though prices are hardly quotable at a lower level. One influence has been the end of the slow movement on railroads, caused by the bad weather, and another has been the failure of the iron and steel industry to show any further improvement. A fortnight ago the railroad movement suddenly slowed down, and while shipments kept up very well the coke was longer in transit, resulting in demand for extra shipments on contract, with a little demand in the prompt market. In the past few days the belated coke has been arriving in heavier tonnages and the tendency now is rather to ask for suspension or curtailment of shipments. As a result the spot market is a trifle easier. The contract market is not particularly affected, since there was hardly any negotiations. Practically all consumers are

covered by contracts to Apr. 1, but a few contracts expire then. There is now, however, little interest in the second-quarter market. The present iron and steel outlook is for stationary blast-furnace operations, hence no increase in consumption. The market remains quotable as follows: Prompt furnace, $2; contract furnace, $2@2.10; prompt foundry, $2.40 @2.50; contract foundry, $2.40@2.60, per ton ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ending Feb. 28 at 313,870 tons, an increase of 10,710 tons, and shipments at 341,-784 tons, an increase of 17,614 tons. The shipments reported exceed the reported production by 27,914 tons, and it is stated that the Frick company, the steel-corporation subsidiary, moved 20,000 tons of stock coke in the week.

BUFFALO

Anthracite trade slacking off and not likely to be resumed. Demand for bituminous somewhat better. Winter conditions continue. Coke still dull.

Bituminous—The demand for bituminous is better than it has been lately, though the producer is somewhat handicapped by the special activity of slack, with which certain of the consumers appear to be stocking up against a possible suspension of some length next month. Opinions differ as widely as ever in regard to a suspension. Buffalo jobbers are sending out advices to their customers, but they are careful not to say that one thing or the other is going to happen. The safe thing is to buy a supply when it is to be had.

It is the desire of all operators to allow the mines to remain idle until such a time as the supply is so nearly exhausted there will be some snap to the market. Some members of the trade imagine that the final agreement may include a 30-day suspension, but this hardly seems probable. The difficulty is that the men want to work and there is not a sufficient number of operators who will close down in the face of any sort of demand for coal.

There is a pretty slow movement of cars on account of the snow, which is heavy in most parts of Pennsylvania, but does not interfere with traffic from here Northward or Vestward. There has not been much snow in the West this winter. Reports from the stocks on Western lake docks state that the surplus is not nearly so great as it was, but March will have to take more than the average amount to carry it off.

Coke—It is probable that the coke trade is a better barometer of the general business of the country than coal and the fact that it does not improve materially is significant. Prices remain quiet on the basis of $4.50 for best 72-hr. Connellsville foundry. It will not show much strength until iron is moving faster.

Anthracite—The demand is falling off fast and will be down to the usual low point of the middle of March when that date arrives. The weather is not cold and besides the orders will soon all be for April delivery. There is little coal here, as the mines have not run strong of late and the snow is heavy. Shipping agents are not making very prompt deliveries on that account. The heavy ice in harbor makes it difficult to move lake craft, though a little coal will be put afloat by one or two shippers. Opening rates will be paid, as the time is so near at hand.

TORONTO

Tendency to stock against a possible suspension and trade better.

Trade has been good in all lines. The yards are well stocked and deliveries coming forward freely with less difficulty with railroad blockades than was experienced last year. There is some disposition on the part of dealers to give large orders for bituminous so as to provide against a possible shortage as a result of labor troubles in the bituminous fields.

Quotations remain unchanged as follows: Retail, anthracite egg, stove and nut, $8.25; pea, $6.75; bituminous steam, $5.25; screenings, $4.35; domestic lump, $6; cannel, $7.50. Wholesale f.o.b. cars, three-quarter lump, $3.85; screenings, $3.

TOLEDO

Continued cold weather has cleaned up stocks. Great scarcity of Pocahontas. Fairly good demand of steam grades in anticipation of a possible shut-down of the mines. Pittsburgh No. 8 strong.

There is less coal on hand in the Toledo markets than any time heretofore this winter. A continued spell of the real winter weather cleaned the stock of domestics. Being now accustomed to the uncertain weather of this winter dealers do not care to take any gamble with it, especially now that spring is about due.

Pocahontas has been tight, with prices holding firm. The steam-coal market was slightly stimulated the past days as a result of the agitation over a possible shut-down at the mines. Some of the large factories are, however, still holding off negotiations for storage stocks, but they are watching conditions closely, and if the final meeting of the miners and operators should fail to arrive at an agreement there will likely be a stampede for coal. As it is, the factories seem loath to entirely abandon the hope of buying at the reduced rates after Apr. 1. On the other hand, most of the railroads have already a 35-day supply on hand.

Traffic is not moving as freely at Toledo as might be expected. Most of the dealers find considerable trouble in procuring shipments.

Prices are holding to the following:

	Pocahontas	Hocking	Jackson	Pomeroy	Massillon	Pittsburgh	Cambridge
Domestic lump..	$2.25	$1.25	$2.50	$1.75	$2.50	$1.40	$1.40
Egg.....	2.25	1.25	2.50	1.50	2.50	....	....
Nut.....	1.75	0.80	2.00	1.75	2.50	1.35	1.20
¾ lump.....	....	0.90	....	....	....	1.20	1.20
Mine-run.....	1.40	1.15	....	....	....	1.10	....
Slack.....	....	0.70	....	....	....	....	....

COLUMBUS

Movement improved, but demand is still far from absorbing the possible output. Car shortage hampered operations some. Price list well maintained and there is an increase in stocking-up orders.

The trade continues to improve under the influence of better orders for both domestic and steam grades. The price list is being upheld in every respect and there are few cases of cutting to force trade. The market is in a waiting attitude due to uncertainties in the future. The mine-run law together with the rather unseasonable weather has set aside all former precedents.

The steam business is fairly strong in every particular. Some of the larger steam users are stocking up, although that movement is not as large as might be expected under the circumstances. The fact remains that most of the steam consumers permitted their regular shipments to come forward during the winter, when their consumption was not large and consequently a considerable stock was accumulated; they can also secure West Virginia coal in sufficient quantities to keep them going. Railroads are said to have stocked up for about 60 days.

In the domestic trade demand is fair from dealers, but they are only buying in small orders, as their efforts are directed toward cleaning up, rather than collecting stocks. There is a fairly good demand for anthracite, Pocahontas and the rescreened varieties from West Virginia.

Because of the lack of equipment and the severe snow storm, railroads have been having difficulties in moving coal. Empties have been slow in being returned and many of the mines with orders, had to curtail production. As a result the Hocking Valley only produced about 50% normal and eastern Ohio the same. In the Pomeroy Bend district the output is estimated at 70 to 80%.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump.....	$1.50 @ 1.40	.....	$1.50 @ 1.45	$1.50 @ 1.40
¾ inch.....	1.35 @ 1.30	$1.20 @ 1.15	1.35 @ 1.30	1.35 @ 1.30
Nut.....	1.25 @ 1.20	.....	1.30 @ 1.25	1.25 @ 1.20
Mine-run.....	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack..	0.85 @ 0.80	.....	0.90 @ 0.85	0.80 @ 0.75
Coarse slack.....	0.75 @ 0.70	1.00 @ 0.95	0.80 @ 0.75	0.70 @ 0.65

CLEVELAND

Moderately cold weather and a fair demand is keeping the market firm at low prices. The lake freight market has been complicated by an attempt to break the current rate for transporting coal. Chartering at 1913 rates continues.

Although operators have been expecting a flood of orders in advance of Apr. 1, the sales have been only moderate. A large number of companies have stocked, but it was done when the market was more abundantly supplied than at present. There is a tendency toward higher prices on some of the large sizes, but nothing of a substantial nature has developed.

Cars are not as plentiful as they were. The Wheeling & Lake Erie notified some of its shippers to load the cars as fully as possible and on other roads the supply is just about equal to production. The poorer equipment has been loaded with railroad coal and is standing on side tracks along the lines. This storing by the railroads is the only reason, so far as shippers are able to learn, for a shortage of cars.

The Pittsburgh Coal Co. last week canvassed the vessel offices for boats to carry coal to Duluth-Superior and to Port Arthur during 1914 at 25c. The rate to Lake Superior for the last few years has been 30c. and several million tons have

been placed at this rate, vessel managers having refused to consider the lower price. Simultaneously with the effort of the Pittsburgh Coal Co. to break the rate, announcement was made that 1,000,000 tons had been placed with vessel owners for Superior delivery at 30c. One hundred thousand tons of soft coal also were placed for Fort William-Port Arthur delivery this season at 30c. It is now doubtful if a lesser rate will be possible.

Spot sales are a little lower than sales for shipment and away from Cleveland sales are being made on shipment prices. The spot market is as follows:

	No. 8	Middle District	Pocahontas
Lump, 1¼ in.	$2.05@2.15	$2.15@2.25	$3.60
Lump, ¾ in.	2.00@2.10	2.00@2.05	
Egg	.....	.....	3.60
Mine-run	1.95	1.85@1.90	2.75
Nut	2.00@2.10	2.00@2.10	
Slack	1.95@2.00	1.85@1.90	2.60

DETROIT

Lower temperatures and uncertainties in the labor situation have stiffened up the market. Demurrage coal mostly cleaned up.

Bituminous—The local market is a weather proposition, although interruptions to transportation and possible labor troubles are also determining factors. The lower temperatures have helped the market materially, particularly as regards demurrage coal, but the possibility of the strike does not seem to create any important movement. The inclement weather interfered with operations at the mines and the movement on the roads. While a slight stiffening in the market is noted, this is more or less of an artificial nature due to the possibility of labor trouble.

Anthracite—Hard coal is in good demand with some grades commanding substantial premium, due to the difficulty in obtaining prompt shipments as a result of the inclement weather.

Coke—Connellsville 72-hr. foundry coke is quoted at $2.55, with Semet Solvay at $3, and gashouse at $2.65. Local ovens are reported as working full capacity.

HAMPTON ROADS

Shipments from Hampton Roads still slightly below normal. Demand light, although showing some little improvement.

The dumpings over the Hampton Roads piers for the week have been somewhat light, although there have been a number of large shipments both foreign and coastwise. While there is little demand for spot coal there has been a slight improvement and indications are that, unless the weather should turn considerably warmer, the demand will continue to improve. This is especially true on the inland trade.

Prices on all grades at tidewater and inland are the same as they have been for some weeks. The accumulation of coal at all piers is still somewhat above normal but not excessively so. Some of the accumulated coal is being assembled to take care of government colliers about due.

Export shipments for the week have moved to Canal Zone, Montevideo, Trieste, Port of Spain, Cienfuegos, Santiago, Havana and Dakar.

The total dumpings over the Hampton Roads piers for the month of February amounted to 875,783 tons; of this quantity the Norfolk & Western Ry. dumped over the Lamberts Point piers 440,236 tons, the Chesapeake & Ohio Ry. at Newport News 234,685 tons and the Virginian Ry., from Sewalls Point 200,862 tons.

LOUISVILLE

Consumption holding up well, in spite of moderating weather. Prices remain low, due to the lateness of the season and fear of discouraging buying. Car situation good.

The trade has been favored with a continuance of fairly severe weather, causing a continued demand for domestic grades, and buying on the part of the retailers has become quite general. Stocks seem to have been exhausted with remarkable rapidity, indicating that few consumers had any coal on hand.

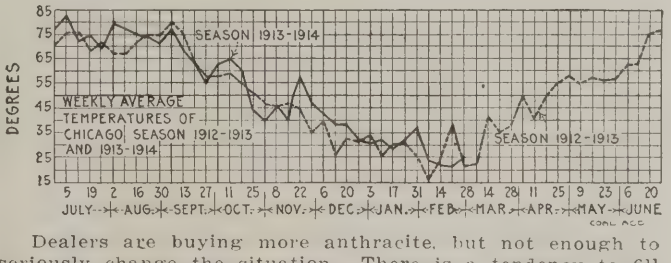
The steam market is fair. The demand is all that could be expected, but the supply is now ample, due to the increased activity at the mines. Those concerns which made price concessions are finding it difficult to get back to a proper level in this department. Talk of possible labor trouble in various fields is becoming general, but seems as yet to have had no effect on the market.

The fact that some mixed coal is being furnished to railroads by eastern Kentucky mines is responsible for the appearance of pea and slack from that section, as there is always plenty of this grade from western Kentucky; the price is low, running around 15c. For nut and slack the price ranges from 55@60c. for low grades to as high as 85c. for the better grades.

SOUTHERN AND MIDDLE-WESTERN

INDIANAPOLIS

Heavy orders for screenings and steam grades. Mines would run full schedule, if sufficient cars were available. Premium prices offered. Domestic market a weather proposition.



While the car service is reported improved, mines are not able to run at more than 80% capacity, and operators seem to have enough to put their mines on full schedule. One of the largest companies of the state says it will not now be able to catch up with orders by Apr. 1, when the wage contract ends, and this applies also to most other companies.

The rush of orders is due almost altogether to the fear of a suspension of work in April. Premiums are offered on all grades, with the exception of domestic lump, the demand for which is a weather proposition. Screenings can be sold for 90c., which is much better than the price prevailing up to the early part of February. There is a premium of about 10c. a ton over previous prices for steam grades. The mine price for domestic lump is around $1.75, with buyers showing anxiety as this coal is not put in stock. February weather made it necessary to consume more domestic coal than in January and December combined, much to the profit of the dealers. The early March weather has been a continuation of the February kind, and business holds good with the retailers. They have made no change in prices, and it is questionable if they will do so, even with a suspension of mining in April.

CHICAGO

Little change in the local market. Buying still comparatively heavy as a result of the continued cold weather. Retailers' storage piles being reduced considerably and they are forced to buy.

Despite the fact that the joint conference has been adjourned with no future date set coal buyers are not showing any trace of anxiety. With only a limited demand for domestic coal, mines are on a short production and as a result there is a reduction in the supply of screenings and the price is advancing.

Dealers are buying more anthracite, but not enough to seriously change the situation. There is a tendency to fill their needs up to Apr. 1 with odd cars or demurrage coal, which they can obtain at a low price. Steady conditions prevail in the smokeless market, but the coal is not unusually active. The Springfield market has experienced an improved demand for steam coal; the evident shortage in the screenings supply has resulted in an increase of 5 to 10c. a ton for this coal. This higher figure has brought out a bigger demand for mine-run, egg and steam lump. There is nothing of import in the coke market, the demand being quiet.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.07@2.17	$2.55@2.65	$2.12@2.27	
Steam lump	1.97		1.97	
Egg		2.55@2.65		$3.70
Mine-run	1.87	2.20@2.25	1.87	3.30
Screenings	1.67@1.77	1.90@2.05	1.67@1.77	

Coke—Connellsville, $5.25; Wise County, $5@5.25; byproduct egg and stove, $4.90; byproduct nut, $4.75; gashouse, $4.50.

MILWAUKEE

Large stocks on hand and little apprehension over the possible labor difficulties.

If all upper lake ports are as well supplied with coal as Milwaukee is, a month or two of idleness at the mines this spring will not cause any great disturbance. It is estimated that there is fully 20% more coal on the docks here than at this time last year. This is true of all grades of domestic and commercial coal.

This condition is not altogether the result of a mild winter, as there has been a fair movement of steam coal right along. It is due in a large measure to the foresight of dealers,

who docked much larger stocks last year than has been their custom, in anticipation of labor complications at a time when supplies are usually at a low ebb.

February was a real winter month from the standpoint of temperature, and the draught upon stocks during that period was the heaviest of the season. From now on the movement is expected to be normal. Prices have been fairly well maintained throughout the season. Shippers and vessel men do not expect the upward movement of coal to begin until early in May.

ST. LOUIS

Coal markets generally stronger all along the line, but with prices still relatively low. Railroads and large consumers gradually accumulating surpluses. Car shortage.

Continued winter weather, cold and threatened snow, has kept the domestic market in fairly good condition, and a good volume of coal is moving. Standard coal, 2-in. lump, has touched 85c. in some instances, with an average of 90c. Carterville 6-in. lump sold around $1.15 and $1.25, while screenings from both have a tendency to increase in price.

As has been intimated before, several railroads and large consumers are buying in five- and ten-car lots and scattering their purchases over a wide territory so as not to cause any undue excitement, and an advance in prices. It is estimated that something like one thousand cars of mine-run coal from the Carterville and other fields were purchased during the past week, for shipment throughout the balance of the month. The screenings market is high enough at this time to warrant bringing in West Kentucky coal, and a local company with mines there has sold two lots of screenings.

In the past the steam plants have been loaded full with high-priced coal, and this year they are skeptical about buying. This will have the result of making some fancy prices in April to those who are not stocked.

There is practically no anthracite or smokeless moving, and the same applies to coke. On Illinois coals it is likely there will be a general advance on all sizes the coming week. There is a serious car shortage on the C. & E. I. and cars are not any too plentiful on the other lines.

The prevailing prices are:

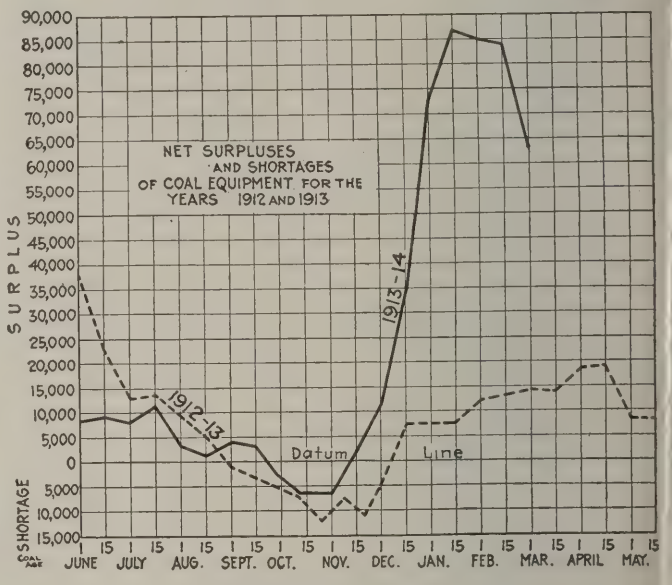
	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	.....	.....	.....	$1.05 @ 1.10	$1.15
3-in. lump	.....	.....	$1.40	.....	.....
6-in. lump	$1.25 @ 1.50	.....	1.50	1.25 @ 1.35	1.25
Lump and egg	1.85 @ 2.15	2.15	.....	.....	1.15
No. 1 nut	1.20 @ 1.40	.....	.....	.....	.....
Screenings	0.75 @ 0.85	.....	.....	0.55 @ 0.60	0.60 @ 0.65
Mine-run	1.10 @ 1.20	.....	.....	.....	.....
No. 1 washed nut	1.50 @ 1.60	2.25	1.50	.....	.....
No. 2 washed nut	1.25 @ 1.35	.....	1.25	.....	.....
No. 3 washed nut	1.25 @ 1.30	.....	.....	.....	.....
No. 4 washed nut	1.25 @ 1.30	.....	.....	.....	.....
No. 5 washed nut	0.75 @ 0.80	.....	.....	.....	.....

KANSAS CITY

Dealers refusing to buy ahead and situation unsatisfactory. Mines working moderately steady and prices fairly well maintained.

The situation in Kansas City and the Southwest is far from satisfactory. Dealers are buying with caution, ordering only for eleventh-hour demand, refusing to anticipate their wants far enough ahead to allow for transportation from the mines. This means that operators must maintain stocks at their sales offices in Kansas City and elsewhere, and the coal is left on track, causing demurrage charges to be added to the cost of marketing.

About five days a week seems to be the average at the mines. The market has been steady at the quotations which have prevailed since the first of the year. Cherokee and Mexican lump is quoted at $2, f.o.b. mines; nut, $1.85; semi-anthracite, $2.50, and Lexington lump, $2.



PRODUCTION AND TRANSPORTATION STATISTICS

ANTHRACITE SHIPMENTS

The hard-coal shipments for February touched the lowest for any normal month since August, 1909. Gross February shipments were 4,121,451 tons as compared with 5,175,732 tons in January, and 5,662,618 tons in December. The total shipments for the two months of the year are only 9,297,183 tons as compared with 12,010,588 tons last year.

Details of the anthracite shipments for February and the two months of this year and last year were as follows:

	February		2 Months	
	1914	1913	1914	1913
Phila. & Reading	746,793	1,165,449	1,761,919	2,422,581
Lehigh Valley	681,844	1,062,129	1,492,432	2,237,280
Cent. R.R. N.J.	563,650	761,070	1,268,141	1,574,437
Del. Lack. & West.	573,553	763,571	1,192,491	1,685,670
Del. & Hudson	442,378	567,371	1,029,271	1,220,548
Pennsylvania	426,100	491,062	962,218	1,067,614
Erie	533,307	655,919	1,239,610	1,373,154
Ont. & Western	153,826	207,598	351,101	429,304
Total	4,121,451	5,674,169	9,297,183	12,010,588

VIRGINIAN RAILWAY

The total shipments of coal over this road for January, 1914, were 407,109 tons, as compared with 453,886 tons for the same month last year.

COAL FREIGHT DECISIONS

I. C. C. No. 4606—Youngstown Sheet & Tube Co. vs. Pittsburgh & Lake Erie R.R. Co.

Rate of 70c. per net ton for the transportation of bituminous coal in carloads from the Pittsburgh, Penn., coal district to the Youngstown or Valleys district of eastern Ohio and western Pennsylvania, not found unreasonable or unjustly discriminatory. Complaint dismissed.

COAL SECURITIES

William J. Hoey reports the market on various coal securities for the week ending Mar. 7, as follows:

Stock	Bid	Asked
American Coal	80	95
American Coal Products	83	84
Amer. Coal Prod. Pfd.	104	106

COAL AGE

Large Hoist Installation

Small Hoist Installation

Westinghouse Hoist Installations
Both Large and Small

The motors and control of Westinghouse Electric hoist installations, designed especially for your service, have embodied in their design features that assure

Maximum Output Under All Conditions

Liberal design of motor makes it possible to hoist increased loads for a long period to make up for time lost in delivering coal, or ore, to the foot of the shaft.

Reliability

Reliability means continuity of service, assuring against loss due to reduced output caused by motor or control trouble.

Ruggedness

The first two points are dependent upon ruggedness of mechanical and electrical construction.

Efficiency

Power consumption per ton output is an important factor. Westinghouse high efficiency means low operating costs.

Safety

All Westinghouse hoisting installations are designed with control arranged to prevent accidents due to overwind, failure of power and errors in judgment of the operator.

Our specialists in mining equipment will be glad to assist you in selecting the proper equipment for your mines. Their services are at your disposal if you will write to the nearest office listed here.

The "Tax" Idea Is Dead

The Weekly Ad-Talk Page

There are some men who cry aloud because they are being compelled to wear a glove of quality, standardized and guaranteed by advertising, rather than an inferior article at an increased price.

These same skeptics have decided that "advertising is a tax on the people."

But in this country of ours advertising is an economic necessity. The distances are tremendous. A manufacturer cannot live on the trade of his county—his salesmen cannot travel a thousand miles over expensive railroads on missionary expeditions.

Branch offices are too expensive unless a demand is already created.

These economic principles have opened dollared possibilities for you.

Instead of listening to the story of one machine, combating with the insistent, compelling personality of the salesman, the buyer can weigh the merits of different types quietly and wisely.

In the privacy of the office, or the seclusion of home, the advertisements in this paper may be set side by side, compared and judged, the mind freely made up, and action taken on the conclusion.

Here, then, is the great benefit, reader, you derive from the selling section of this paper—the right to consider two or more articles absolutely on their merits, irrespective of persuasive personality.

Advertising has grown up. Its message is authoritative. Its guarantee is a contract that fair value will be given for your money.

Therefore your "buys" through a period of years reveal your up-to-dateness, or your lack of careful study.

As a great merchant once said, in an address before a class of business college graduates: "Advertising is an economizer of public time. It saves thought and worry. It tells the business news of the day."

COAL AGE

Vol. 5 NEW YORK, MARCH 21, 1914 No. 12

Motion Studies Applied to Coal Mining

Since Taylor, Gilbreath, Brandies, and others have written on the above subject, or "Scientific Management" as it is more familiarly known, much benefit has been derived from its application and much harm caused by a misunderstanding of the problems involved.

The average workman understands that by "Scientific Management" we propose to teach him how to lift 100 lb. of pig iron, or other material, in such a way that it will not feel any heavier than if he were lifting only a few pounds of material, and he, knowing that such a thing is absurd, very roundly denounces "Scientific Management" as a myth.

Perhaps a better definition of "Motion Study" would be to say that it is the application of common sense to industry rather than the more common practice of forever following tradition.

Not long since there was gathered round the tables of a banquet hall many mining men of experience in their particular branches of industry; a professor of mining engineering in one of our prominent universities was present, and asked the question whether or not efficiency engineering could be applied to advantage in coal mining. One engineer, who had made some motion studies in coal mining, and who had increased the efficiency of hoisting over 260 per cent. in one instance, was alone in his opinion that such a science could be employed to advantage in mining coal.

Perhaps no great industry in the country has shown less advance in the last 100 years than coal mining. For example, the miner of today in the anthracite field, cuts, shoots and loads his coal practically in the same way as did his father or grandfather.

How many operators are there who can give a lucid and sufficient reason for the details in the cycle of operations that have to do with getting the coal from the working face to the railroad car? Are all of the men, animals, material and energy employed to the best advantage of everybody concerned, and is there any lost motion? Can anyone with truthfulness answer the above question in the affirmative for any one mine in any field in the country? Is any man, animal or machine going through useless motion and if so, why? Can any one give the reason why, or why not, an 18-ft. room under given conditions is better than a 14-ft. room, or a 24-ft. room, or no room at all?

Mr. Operator, do you think you are treating your labor in such a way as to remove the present industrial unrest or to increase the present dissension existing when you ask a miner to go into the mines at 7 a.m., shoot his cut, timber his place, clean his coal, load the car that you give him at 8 or 9 o'clock, and load it quickly so that he becomes wet with perspiration, and then not give that miner another car until 12 or 12.30 p.m., or later; because perchance your haulage motor had to chase off to several other sections of the mine?

Do you think that you are working that miner to your best advantage, or his best advantage, and do you feel that while he is sitting on the "parting" wet from perspiration and cold from the swiftly moving current of air, which alas! often does not move at all at the working face, do you think that this group of coal loaders, waiting for a car, have kindly thoughts of you? Do you realize that on an average, as determined by observation, 72 per cent. of a coal-loader's time underground is lost in waiting for empties.

Is the plan of development in your mine such that you can concentrate your workings to the utmost, or does the mine's ramifications extend over 500 acres for a petty output of 500 tons and are you leaving 500 acres of pillars as you go? Is your plan of mining such that the further you go, the more scattered become your workings, or do the miners' working places bear a constant relation to one another?

The writer who has made motion studies of the above cycle of operations, i. e., getting the coal from the face to the railroad cars, ventures the assertion that not only are the present plans of development extravagant of capital, men, material and the natural coal resources, but that there is hardly a motion in the entire cycle that cannot be improved upon, and that a large percentage of same can be entirely eliminated, resulting in decreased cost to the operator and increased earnings to the miner.

Make motion studies of the cycle of operations yourself, forget tradition, apply common sense, and you will become appalled at the extravagance of present methods.

Systematic Timbering and Mine Fatalities

SYNOPSIS—The British Columbia Mining Department has issued a set of rules to govern the placing of all timbers in underground workings. It is hoped that the scheme of enforcing a systematized plan of timbering will reduce the accidents from roof falls.

Loss of life, largely unnecessary, is witnessed each year through faulty or inadequate timbering at the working faces of our coal mines.

British Columbia, spurred by the unwarranted increase in such fatalities during the past year, has taken a decisive step toward eliminating, or, at least, minimizing this danger, in the adoption of a "Special Rule—Systematizing Timbering."

This rule was referred to the mine managers of the province last year in a circular, sent out by the Chief Inspector of Mines at the direction of the Minister of Mines, which was, in substance, as follows:

"For a number of years past, the percentage of fatal accidents from falls of roof and coal at the working faces, has ranged from 35 to 60 per cent. of the total accidents occurring in coal mines. I regret to say that, during the first five months of the present year, there have been 12 fatal accidents—or three more than during the whole of last year—from these causes.

"Owing to the large increase in this class of accidents, the Minister of Mines deemed it necessary to avail himself of the powers given him, as set forth in Sec. 101 of the Coal Mines Regulation Act, and proposes in writing to the managers of the various collieries, a special rule, covering the question of systematic timbering and spragging at the working faces.

"Recognizing that, owing to the widely varying conditions in the different collieries in the province—even in the same field, and often in the same mine—that a hard-and-fast rule on systematic timbering would render such rule often impracticable, making the same invalid and often, even tending to bring about the very conditions it would be aimed to prevent; therefore, before formulating any such rule, the Minister, in keeping with his former policy, would like to avail himself of your assistance and coöperation in this very important matter, so the following proposed special rules are submitted for your consideration."

Special Rules for Systematic Timbering

(A) The manager of the mine shall cause to be posted, at a conspicuous place, near the mouth of the mine, a notice stating the minimum size of the different types of timber to be used in such mine, and the maximum distance between timbers, and between the timbers and the face and sides of the working face.

(B) In the event of two or more methods of timbering being used in one mine, then, in addition to the notice posted at the mouth of the mines, the notice shall be posted at the entrance, to each section or district, stating the method of timbering to be used in such section or district of such mine.

(C) It shall be the duty of the miner in charge of a working place—which shall include such working place and for a distance of 15 ft. back from the face—to keep the props, timbers, or other roof supports erected as designated in the notice of systematic timbering governing the mine, division, or sub-division of such mine in which he is employed.

(D) Nothing in this section shall prevent a miner from setting supports, or an official from requiring the miner to set supports in his working place at more frequent intervals than those specified in the notice aforesaid, if necessary for safety.

(E) Every miner in charge of a working place, shall set sufficient sprags or other supports for the undermined coal, provided that before commencing to mine, he shall set one sprag or other support, and not less than one for every six feet of such undermining.

(F) Temporary props shall only be withdrawn by use of a dog and chain or othr type of timber-drawing machine, unless permanent timber has been set before such withdrawal, and no permanent prop, timber, or other roof support shall be finally withdrawn without the use of such timber-drawing device.

The large majority of the managers in the province heartily approved the Minister's suggestions and all, with the exception of two or three, who have since complied, were in a position to start the present year under a method of systematic timbering.

The special rule, as finally adopted, is uniform throughout the province; the method of timbering under the rule having been provided for, to suit the local conditions of each mine affected.

The adoption of this rule is undoubtedly a step in the right direction, and the records of British Columbia for the current year should most certainly prove its justification.

Excerpts from Advanced Sheets of Penn. Bituminous Report, 1913

The following extracts taken from the forthcoming report of Mine Inspector Charles P. McGregor are worthy of careful attention:

Accidents—The responsibility for preventing accidents falls upon both the mine officials and the employees and if they would do their clear duty there would soon be a happy change.

Equipment—Even where many improvements (in the mine equipment) are in place, we too often find, in the mine, that brattices and doors are begrudged, roads badly kept; while a cheap, hard-worked mine official either wades contentedly in and out through mud and water or vainly strives to keep up a show of good order and repairs. But just as soon as operators supply thoroughly reliable plants and machinery and insist on everything being kept in proper order and repair underground as well as on the surface good results will be shown financially.

Certification—A good engine or electric motor is more easily obtained than a good mine foreman. * * * Many a worthy man is turned down, who though he can manage a mine cannot write out an examination paper; while another, whose whole experience has been gained as a miner, mining engineer or man of general work inside of the mine has, by night study and self-education, so improved his mind that he has been enabled to secure a mine foreman's certificate. In making an examination

imperative the law has done all it should do in the matter and it now rests with the Examining Board to carry on the work from this point. * * * There should be on our statute books an imperative law requiring a mine superintendent to hold a certificate of competency as well as the mine foreman.

The Superintendent—To secure an efficient superintendent or mine foreman a good salary should not be denied, and many coal companies have made large advances in recent years in this respect. The increased responsibility put upon mine officials renders this absolutely necessary and such encouragement leads capable young men to seek the office. Employers, however, might urge and encourage their officials not to be content with a certificate of competency, but to press on ever to higher and deeper knowledge in their profession and as a body they might institute other examinations in theoretical and practical mining, wherby real merit would be discovered and a higher order of certificates awarded.

Education of Workmen—The ignorant will always be thoughtless and

"The evil wrought by want of thought"

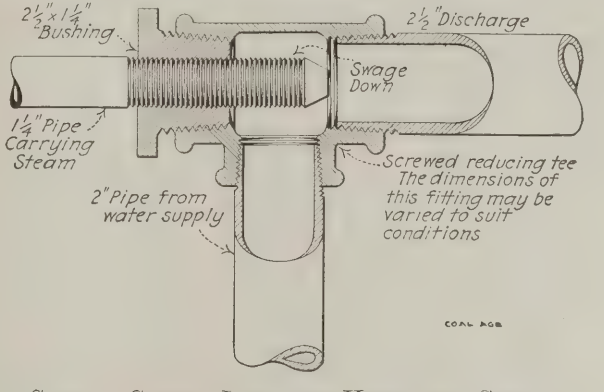
in our mines is but too amply seen in the list of fatalities by falls of slate and coal, mine cars and explosions of firedamp.

Many companies have already established well equipped evening schools. There should be on our statute books a compulsory education act compelling all boys from 14 to 18 years of age to attend evening schools.

Discipline—Hurry and confusion inevitably lead to accidents. Order and safety generally go together. Repairs put off or carelessly performed jeopardize the lives and limbs of the men, and the mine officials in charge should have a quick eye to detect flaws and adopt improvements as they appear. Neither personal talent nor energy will compensate for the want of discipline. Rules and laws must not be merely printed but obeyed. * * * It is not possible to estimate the value of discipline too highly. It is a most important element of success. The men, both young and old, should have this constantly impressed upon them. The special and general rules should be read and explained to them regularly and the conduct of the subordinate officials as to sobriety and punctual attendance to duty should be constantly observed and properly regulated.

You Can't Afford to Miss Our Next Issue

COAL AGE next week will contain a number of articles of great interest and value to every coal-mining man. First there will be a description of one of the largest retort-oven installations in England, with interesting notes relative to the advantages of the "Koppers" process. Then there will be a description of an uptodate coal plant in Virginia. Next will be an article on the prevention of coal-dust explosions, giving the most recent recommendations of noted British authorities on the subject of applying stone dust. Following that you will find an article on the construction of workingmen's houses. This article describes the introduction of hollow-tile for building miner's houses at the L. C. & N. Co.'s Hauto plant in Pennsylvania.



If none of the foregoing articles arouses your keenest interest, there are others that will surely appeal to you. One of these is entitled "Converting the Foreman to the Safety First Idea," and points out the tendency of the busy mine foreman to ignore the "safety-first" idea, until converted to it by the occurrence, under his charge, of some preventable accident. Still another article deals with "first aid to the injured," and gives practical suggestions regarding the best procedure in event of serious mine accidents.

We will also publish another of Mr. Braley's poems, which have become famous in every coal district of America. The next few weeks will witness the publication in COAL AGE of the most valuable and diversified list of articles ever collected for the benefit of coal-mining men.

A Small Water Lift

Where small amounts of water either under or above ground are to be handled about a mine, a steam lift, similar to the one shown in the accompanying drawing, may be easily made from pipe fittings.

One point should be noted, however, namely, that the tip of the nozzle should extend beyond the side opening or outlet of the tee, in order to produce the best results. If a device of this kind is properly constructed and installed, it is no trouble to make it lift water 6 ft. or

SIMPLE STEAM LIFT FOR HANDLING SMALL AMOUNTS OF WATER

more, while it can be made to discharge against a much higher head.

As will be clearly seen, this home-made lift works upon the well known principle of the injector. It may be argued, and rightly so, that this device is extravagant in the use of steam. While this is admittedly true, yet it possesses advantages which, to a large measure, offset its steam-heating capacity.

Among these advantages should be mentioned that it is small, light, can be easily and cheaply made, is simple in construction, has no valves or moving parts to get out of order, and is not nearly as liable to freeze up in cold weather as is an ordinary steam pump.

BY THE WAY

Be sure to forget the benefits you confer.

It isn't easy to blow and swallow at the same moment.

Three persons can refrain from quarreling if two are away.

Weakness of mind is not the only great fault a man may nave.

Coal Handling at the Atlantic Coast Piers

By James Steelman

SYNOPSIS—A general description of the chief loading ports on the Atlantic Coast. The relative importance and growth of the various harbors are discussed. The development and comparative merits of different handling apparatus are also entered into.

It is probable that few, outside of the circles immediately concerned, realize the extent of the business of unloading coal along our Atlantic seaboard. Every year, more than 44,000,000 tons—1,000,000 carloads—are dumped into vessels for shipment coastwise and to foreign points. If the work were carried on steadily, instead of in a more or less irregular manner, each ten-hour working day in the year would see about 3300 carloads deposited in holds.

Lehigh Valley R.R. Co.'s Plant at Perth Amboy, in New York Harbor

This is quite a business and requires equipment and other facilities having a capacity far in excess of the average tonnage handled, for the reason that the maximum and minimum requirements are widely separated. A coal pier will be operating at capacity one day and the next the plant will be idle. And yet, it must be ready for its maximum business or at least a considerable increase beyond its daily average. While the coal piers of the principal Atlantic harbors actually handle only 1,000,000 carloads per year they have a capacity of 3,000,000 loads. If operations could be continuously at capacity, an equipment of 65 per cent. less than the present one would suffice.

The Atlantic seaboard of the United States possesses four large deep-water harbors, New York, Philadelphia, Baltimore and Norfolk. These are the coal harbors and they have channels varying from 35 to 40 ft. in depth. The mean tidal fluctuations range from 1.2 ft. at Baltimore to 5.3 ft. at Philadelphia. The maximum variation in the tide, 6.3 ft., occurs at New York.

New York Harbor

New York harbor is the greatest. It alone possesses thirteen ports served by nine different railways. Its capacity is sufficient to take care of the total discharge of coal for the entire group of four harbors, if only operations could be made continuous and at capacity. Here we have what is by far the longest coal pier on the Atlantic coast. It measures 1800 ft. from bulkhead to end of slip; it is located at South Amboy, N. J. Two others, each nearly as long, are situated at Harsimus Cove and Port Liberty, N. J. In fact, there are in New York harbor nine coal piers whose combined length totals 13,490 ft., an average individual length of about 1500 feet.

There are others whose lengths are unknown but whose capacities are such as to lead one to suppose they also belong to the class of long piers. However, it is not always the long pier that really has the greatest unloading facilities. Thus, at Port Greenville, N. J., a part of New York harbor, there is a 400-ft. pier having as great a capacity as the one already mentioned having a length of 1800 feet.

At New York, the coal is delivered mostly to small vessels—lighters and barges ranging up to 3500 tons cargo

capacity—which distribute it locally. There are but few coal cargoes for ocean shipment taken on directly from the piers. So, while New York harbor delivers much more coal to vessels, its facilities for the direct loading of large ships are, it would seem, inferior to other coal harbors of the Atlantic group. However, New York operates its equipment much nearer to capacity than any of the others. According to J. E. Greiner's analysis, New York operates at about 51 per cent. of its capacity, while the others cling to the neighborhood of 30 per cent.

Varying Pier Heights

If we include plants now under construction, Norfolk harbor is entitled to rank next to New York in respect to coaling capacity. At New York, 4350 carloads may be discharged daily into vessels; at Norfolk, the new construction will bring the daily capacity up to 3180 carloads and cargoes up to 12,500 tons may be loaded directly from the piers.

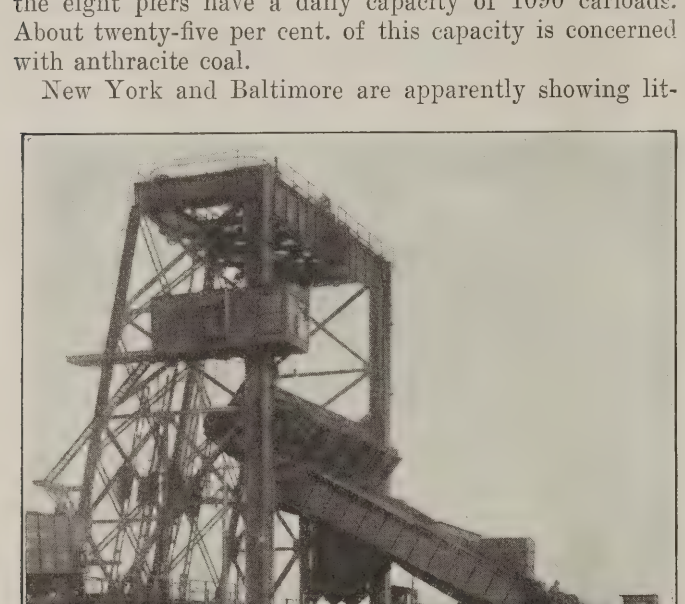
This problem of loading directly from pier to vessel is made difficult by tidal fluctuations and more especially by the variations in the height of the hatches, occasioned by varying amounts of cargo on board. An empty ship on a flood tide presents its hatches at quite a different level than when loaded and floating on the ebb. The vessel moves up and down with the water and also with the variations in load. It is necessary that the dumping apparatus shall operate above the highest level attained by the hatch and shall also be able to deal satisfactorily with the lowest point. If the mode of dumping is a pure gravity arrangement, the pier should be from 33 to 43 ft. above the highest hatches to be loaded at mean tide.

In Norfolk harbor are located the highest piers of the group. The Norfolk & Western Ry. Co.'s Pier, No. 3, rises to a height of 70 ft. near the outer or sea end. The pier of the Virginian Railway Co. is only a foot lower, while two others now under construction will be about 91 ft. high. These four piers will put Norfolk far ahead of the other harbors in respect to its capacity for loading with the largest vessels. Philadelphia has a single pier of 66-ft. height already built and another of 62 ft. under construction, while Baltimore has two piers, 59 and 60 ft. high.

It might be thought, at first glance, that any arrangements that would take care of the highest condition of the vessel would, as a matter of course, also provide for the lowest condition. But the distance of fall must be kept within a minimum.

The number of piers at Norfolk will be 10 when the two now under construction are completed. Their average loading capacity is 318 carloads per day while at New York, the average is only 150 carloads. At Philadelphia, the capacity is 203 carloads and at Baltimore, 136 carloads. It will thus be seen that the piers at Norfolk, while not the most numerous, are yet much superior to those of the other harbors.

If we take note of the fact that New York has apparently no important piers under construction, we may say that Norfolk seems to be fast overhauling the northern harbor. It deals with the largest coal vessels and its daily loading capacity will soon be high. It is quite



Carload of Coal Being Dumped at South Amboy Piers, New York Harbor

possible that Norfolk will become a great coaling point, for the reason that its business is chiefly for outside delivery. At New York, the metropolis and its environs constitute probably nearly the whole of the ultimate market except the bunkering coal.

The Principal Harbors

The harbor of Philadelphia undoubtedly ranks, at the present moment, next to that at Norfolk, having a daily capacity—if we include two piers now under construction—of 2640 carloads, or more than half that of New York. It has 13 ports served by three great railways, the Pennsylvania, the Baltimore & Ohio and the Philadelphia & Reading. No doubt, a very considerable percentage of the coal unloaded at this port is consumed locally, just as is the case at New York. At Baltimore, the eight piers have a daily capacity of 1090 carloads. About twenty-five per cent. of this capacity is concerned with anthracite coal.

New York and Baltimore are apparently showing little interest over increasing their capacities. It is possible that the demand for additional facilities is slight. At Norfolk and Philadelphia, the new construction under way means a total increase in capacity amounting to 1860 carloads per day, or over 40 per cent. of the entire capacity of the thirteen ports and twenty-nine plants in New York harbor. The total pier length of the new construction amounts to 3965 running feet.

Car Dump at the L. V. R.R. Pier, at Perth Amboy

If we separate the bituminous and anthracite capacities, we find at once that New York is far and away the leading harbor. Her capacity for anthracite unloading totals 2700 carloads per day or 62 per cent. of her gross capacity. It is not very clear how Philadelphia harbor stands in respect to handling anthracite coal, but it must be that her position is far below that of New York. Baltimore has a capacity of 260 carloads per day, while Norfolk confines her activities to bituminous coal alone.

Thirteen railroads participate in bringing coal to the piers of these four harbors, the principal ones being the Pennsylvania, the Philadelphia & Reading, the Baltimore & Ohio, the Chesapeake & Ohio and the Central Railroad of New Jersey. These five lines carry 72 per cent. of the coal that is discharged at these four harbors. No one road carries to all. At New York and Philadelphia, the Pennsylvania is the leading carrier and at Baltimore, it stands second. The Baltimore & Ohio serves precisely the same three harbors; it leads at Baltimore, delivering to the unloading piers nearly half of all the coal handled. New York harbor is served by nine railroads and all the others by three each.

Methods of Handling at the Piers

There are three principal methods of discharging coal at the piers. When the coal is brought by gravity alone from the cars to the bins on the pier, or to the holds of the vessels, the pier is rated as a gravity plant. There are in use at the four coal ports of the Atlantic seaboard five different types of gravity unloading arrangements. The simplest of these is where the loaded cars are simply run out on a level pier and returned in the same way. Locomotives are required for handling both the loaded and the empty cars. The expense of this method, under favorable conditions, is not excessive for the reason that a considerable number of cars may be handled at one time. Altogether, there are in operation six piers of this type, two at New York and four at Philadelphia. It is uncertain when those at New York were built, but none at Philadelphia were constructed since 1865. We may, in view of this latter fact, regard the type as obsolete or obsolescent.

Another type of plant is that where locomotives run the loaded cars out on a level pier and the empties are returned by gravity. New York possesses the only two piers in this class. Although apparently economical, because of the possibility of handling strings of loaded cars by single locomotives and because of the simple method of return, they do not appear to be at all popular. One reason for this is that it is quite often impossible to construct a grade track out to the end of the pier at a sufficiently high level.

This idea is confirmed by a consideration of the pier where the loaded cars are pushed up an incline to the deck and the empties returned either by locomotives or by gravity. This is a popular type, 21 piers being constructed on this principle, 11 are at New York and the remainder at Philadelphia and Baltimore. While New York has no high piers, none exceeding 40 ft., all those over 30 ft. are constructed as just described. There are seven with heights from 32 to 40 feet.

The next most popular type is where the locomotives push the loaded cars up to a crest from which they drift by a slight downgrade to their unloading positions, the empty cars being returned by gravity; 14 piers of this class are now in operation, all four harbors having two or more.

A modification of the last type of pier is one where the loaded cars come down grade toward the sea to the foot of a steep incline up which they are pushed or pulled, by a cable arrangement, to a point higher than the final height desired. From this position they are allowed to drift down a slight grade to their unloading positions. They are then returned by gravity. All the harbors have one or more plants of this character, all the highest piers at Philadelphia, Baltimore and Norfolk belonging to this type.

Increased Use of the Mechanical Plant

Of the 56 coaling plants already constructed at the four harbors, 49 are to be classed as of gravity type, and one more is now under construction at Philadelphia. In New York harbor, however, there are six mechanical plants which have all been constructed since 1900 and another is under construction at Philadelphia. At Norfolk, one plant already constructed (in 1909) and two others under construction, all include mechanical handling in some way.

If we weigh these facts against the single gravity plant under construction at Philadelphia, we see that the influence of mechanical methods has already begun to extend itself to the discharge of coal from pier to vessel. When the new construction now under way is completed, mechanical operation will be the chief or an important factor in ten plants whose total capacity will be 2990 carloads per day.

In New York harbor, there are at South Amboy, N. J., two mechanical loading plants; at St. George, Staten Island, one, and at Hoboken, N. J., three, making six altogether. These have a combined daily capacity of 1190 carloads. The three at Hoboken handle anthracite coal; one at South Amboy both anthracite and bituminous; the remaining two, one at South Amboy and the other at St. George, bituminous. In Philadelphia harbor, at Greenwich, a mechanical plant is under construction which will have a daily capacity of 300 carloads. There are no mechanical or semi-mechanical plants in Baltimore harbor but in Norfolk harbor there is a plant which combines mechanical and gravity features having a daily capacity of 300 carloads. At Lamberts Point, Va., and Newport News, Va., two great combination plants are under construction. When finished, these piers having a daily capacity of 600 carloads each will rank as the leaders on the Atlantic coast. They will be 1200 ft. long and have a height of 91½ ft.; either will surpass in height by 21 ft. the present highest pier, which is also located in the same harbor.

Method of Working the Car Dump

Five of the New York mechanical plants and the one under construction at Philadelphia operate on the same general principles. The car together with its load is made to ascend a steep incline, the power being applied by a locomotive or cable arrangement, to a device known as a "cradle." This is a piece of apparatus in which the loaded car is securely held and by means of which the whole may be elevated to the level from which the dumping is effected. This elevation is vertical; when the cradle and its car have reached the desired height, it is dumped over sideways. The coal runs onto an apron, and then into a chute which guides it into the open hatch of the waiting vessel. The cradle is then righted and lowered to its original position when it is ready to receive another loaded car. The empty car is returned by gravity.

In addition to the six plants at New York and Philadelphia, this method is employed in connection with a gravity pier and two others will be used in gravity piers now under construction, all three being in Norfolk harbor.

Another type of mechanical unloader is in operation at Hoboken, N. J., in the harbor of New York. This is a small plant, having a daily capacity of only 10 carloads. The coal upon being dumped is received by a hopper and then raised to the desired height by an endless chain conveyor which deposits it in bins from which it finds its way, by means of chutes, to the hatch openings.

The three combination plants differ, however, in the type of gravity pier employed in connection with the unloaders. Two great plants are under construction in Norfolk harbor on which the regulation railway cars are brought one by one into position on the cradle of a car dumping tower. When the car is overturned, the coal finds its way into a special form of car used on the dock. The empty railway car goes back by gravity to the yard and the loaded dock car passes by gravity or possibly by its own power, to the platform of an elevator which lifts it to the dock of the pier. It then drifts by gravity or

Virginian Railway Pier, at Sewall's Point, Va.

again under its own power to its position over the pockets. As already noted elsewhere, these plants will have a daily capacity of 600 carloads and will discharge on both sides which have 62 and 66 chutes respectively. They will probably be the two piers having the greatest capacity in the world.

The Practical Operation of a Coal Pier

The combination plant at Sewall's Point, Va., in Norfolk harbor is of recent construction, dating from 1909. The length of the pier is 1000 ft., both sides of which are used for coaling. There are 62 chutes, and the daily capacity is 300 carloads. The loads of the railway cars are overturned in a car dumping tower and find their way, load by load, into special dock cars. The former go to the yard under gravity and the latter are pushed or pulled up a steep incline by means of a cable to the shore end of the pier deck. This end is higher than the one next the sea, so that the cars pass along by gravity or "under their own control" to the pockets from which the coal is delivered to the vessels. The empty dock cars re-

turn by gravity, under brake control, to suitable positions near the car-dumping tower.

The practical operation of a large coal pier involves a multiplicity of activities. There is the office force, to begin with; on one pier the expense for this item amounted in 1911 to over $8000. Then there is the policing of the structure; for the same pier, the 1911 expense was $1416. These two items put a tax of a little less than one-half cent per ton on the coal discharged. Where the pier requires the loaded cars to be pushed or drawn up an incline, we have the items of locomotive service or of the other machinery operating on the incline.

Where no mechanical arrangements are provided for dumping the coal, there will be a considerable amount of labor required. Thus, for a good sized pier having a daily capacity of 300 carloads and actually averaging 200, there will be required, according to Mr. Greiner, about 64 men and one foreman. If conditions are favorable, a gang of eight men will unload a car in two minutes, but, when unfavorable, as where the coal has been frozen, three-quarters of an hour may be consumed by the same gang, with a single car. When the coal is delivered into the hatches, there is still the matter of trimming; that is, the upper surface must be shaped off. This is really a considerable item, costing in fact more than the unloading.

It appears that the expense of handling coal with the mechanical car-dumping equipment is distinctly less than where gravity and hand labor are depended upon for the service. Mr. Greiner estimates that gravity piers of the ordinary type are able to perform the duty of unloading into vessels at 6.32 to 6.41c. per ton; whereas the mechanical method permits a reduction of 1.76 to 1.85c. per ton upon these costs. However, there may be an expense for bringing the loaded railway cars to the cable, or to the car-dumping tower. Under such conditions, the gravity piers having a cable incline or the mechanical car-dumping plants would have to add something to their costs per ton. The mechanical plant will still show a distinct advantage amounting to 1.25 or 1.85c. per ton.

West Virginia's American Rivals in the Pacific Market

By W. A. MacCorkle*

SYNOPSIS—The author declares that the Pacific rivals of West Virginia have such serious disadvantages in the quality and disturbed character of their deposits that they cannot seriously compete. The Big Warrior canal, in Alabama, is not conceived on a large enough scale to promise brilliant success as a coal carrier. Pennsylvania is crippled by the diverse interests of her ports and of her railroads and is not encouraged to export coal by sea because there is already so generous a market at home. West Virginia will be easily chief of exporters when her canal system makes an all-water route available.

There are deposits of coal near the Pacific Ocean in our own country which demand consideration, and these, like some other coals of our Pacific rivals, merit consideration because they are located conveniently to the markets demanding them. Such are the coals of Alaska and Washington.

It is stated that there are enormous coal deposits in Alaska and that these coals are of prime quality. They may, in future years, become competitors with those of West Virginia, but I do not believe that they will ever compete with our coal until that far-off day when competition will not hurt us. With a distance of 6400 miles to the canal, with an inhospitable climate from 10 to 40 deg. below zero, with the necessity for every supply being brought long distances to the mines, and with labor to be imported and necessarily high, I believe that the cost of production will be so great that the product must reach shipboard at too great an expense for competition with our cheaply produced coal.

Competition with State of Washington

The State of Washington has six or seven coal areas which have been in operation to a limited extent since 1860, and are now producing about 3,500,00 tons per year, at an average price at the mines of $2.39 per ton of 2000 lb. As a rule, these coals are high in moisture and ash, and have a comparatively low heating value.

Forty-nine determinations which are representative of this state show an average of 10,923 B.t.u. Ninety-eight determinations of New River coal show an average heating value of 15,232 B.t.u., or almost 50 per cent. more than Washington coals. The average value of the smokeless coals at the mines, during the year 1912, including New River and Pocahontas, was a fraction under $1 per ton, so that the actual cost of our coals at Newport News or Norfolk is practically the same as the cost of the Washington coals at the mines. We do not believe that this coal will be a strong competitor of the West Virginia fuels.

The Alabama Fields Cannot Compete

In the popular mind the formidable competitor with the West Virginia coals for the Panama and American coast trade is the Alabama coal. An analysis of the situation shows that the popular belief is not founded upon fact. In the first place, a vast quantity of the best coals is reserved for several of the great steel-making corporations of that state.

The expectation of Alabama is to get its coals to Mobile by self-propelling barges. The coal will be transported along the Warrior River for 370 miles, passing through several locks. A channel depth of 6½ ft. with a width of 125 ft. is to be secured but the restricted dimensions

*Ex-governor of West Virginia.

Note—Abstract of last part of an address entitled "The Relation of West Virginia Coals to the Panama Canal," read before the West Virginia Coal Mining Institute, Charleston, W. Va., Dec. 8, 1913. The first part entitled "The Price War in the Markets of the Pacific" appeared Feb. 14 in Vol. 5, pp. 284-285. The second part entitled "West Virginia's Foreign Rivals in the Pacific Markets" appeared Feb. 21 in Vol. 5, pp. 360-361.

preclude the possibility of shipping large barges to their ultimate destination on the Panama Canal without reloading in transit. The river is tortuous and the water transportation today touches only the edge of the field. For many years much of the coal must be transported by rail to the river, loaded in barges and reloaded in seafaring vessels at Mobile.

The extent to which Alabama may become a competitor with West Virginia in foreign trade is practically answered by a study of the following figures, which show upon an analysis that Alabama can never become an enormous competitor with West Virginia in this field:

	Year	Alabama	West Virginia
Production	1912	16,100,600 tons	66,786,687 tons
Value at mines	1912	$1.29 per ton	$0.94 per ton

Alabama used 4,585,498 tons of coal in its coke ovens —equal to 28 per cent. of its entire production.

The United States Census returns, based on the business for the year 1909, show the following interesting comparisons:

Capital investment per one ton of annual production: Alabama, $3.17; West Virginia, $2.64.

Value of coal at mines: Alabama, $1.19 per ton; West Virginia, 86c.

Production costs, including wages, salaries, supplies, royalties and miscellaneous expenses in Alabama, $1.12 per ton, in West Virginia, 83½c.

Our New River and Pocahontas coals have far greater heating value than those of Alabama, and they can be delivered at Hampton Roads at a lower price than Alabama can quote either at Mobile or New Orleans.

The sailing distance from Hampton Roads to Colon is 1778 miles, and from Mobile to Colon, 1376 miles. This relatively small inequality in distance makes practically no difference in the rate to the Panama Canal, and shows almost conclusively that this field, which is largely engaged in consumption as well as production, will not be a formidable competitor.

For many years to come, the loading ability of Norfolk and Newport News will be superior to that of Mobile. The loading facilities at the West Virginia ports are as good as, if not better than, any in the world, and will only be surpassed by the wonderful loading machinery which is now being provided at both ends of the canal by the United States Government.

Alabama will certainly ship some coal in competition with West Virginia, but in the further harbors, and in the Panama market, she will not compete as vigorously as is popularly supposed.

New York City Too Valuable a Port for Coal Shipment

Let us consider briefly our competition with Pennsylvania for this export trade. The ocean port at which Pennsylvania coals are loaded, is New York Harbor. The great bulk of trade of Pennsylvania is not competitive with that of West Virginia. Her facilities for loading in the crowded harbor of New York will never be sufficiently great for the coals shipped from that port to dominate in the foreign markets. The harbor space is too valuable to be reconstructed for coal exporting and consequently its loading provision cannot compete with the great facilities at Norfolk and Newport News. In addition to this, her access to the shores is over a crowded and congested railroad. Our approach is over the railroads which have for their chief business the carrying of coal, and our loading points are those expressly provided for the freighting of a great ship at the rate of more than 1000 tons per hour.

Philadelphia, by reason of its natural situation, will not participate largely in export production. In fact, Pennsylvania as a whole, by reason of her enormous and increasing consuming ability, will be less and less a competitor in the more distant export field. She is devoting her energies largely to her great trade at the Lakes, in Canada and New England. While our coals are the equals of those of Pennsylvania, West Virginia does not compete in the Eastern part of the United States with that state, except on water-borne coals to Providence, Boston and Portland.

Pennsylvania to Decline in Exports

Pennsylvania will, year by year, relatively become less and less an exporter of coal. Her enormous consumption will mean the gradual relative reservation of her field for her own use and she will not seek new markets. This export market from its nature and the position of Pennsylvania will not be one sought by our great competitor in the coal trade.

This has been recognized by several of the great masters of the coal industry. E. J. Berwind, with the great foresight which has characterized his dealings in these matters, recognizing that these conditions will obtain, has invested millions in West Virginia coal, which he is using largely for the foreign markets, especially for the West Indies.

Even Maryland Is Not a Competitor

Maryland last year shipped less than five million tons of coal. While relatively not far from the market, the short haul does not give it the desired control. Our Fairmont region is further away, but is shipping West Virginia coal into Baltimore in competition with that of Maryland. The Maryland coals are unequaled for smithing purposes, and those who are familiar with the situation do not look upon her as a formidable competitor with West Virginia.

It will be noticed that I have included the Pocahontas field with West Virginia in this discussion, though part of that field is in Virginia. The Government of the United States, and largely the steaming trade also, have accepted the Pocahontas and the New River as the leading steaming coals of the world. One cannot consider them apart, even though an area of the Pocahontas deposit is in another state.

How Canals Will Help West Virginia

Another great factor which will aid in the cheap delivery of West Virginia coals is the river transportation of the state. West Virginia, with western Pennsylvania, is uniquely situated in this particular. She is on the line of the cheapest water transportation in the world. In this statement I include eastern Kentucky, which, in regard to river transportation, possesses practically the same advantages as are possessed by West Virginia, and a great part of this field is under the control of, and operated by, West Virginia capital.

The United States is making the most comprehensive water improvement along the Ohio and Mississippi Rivers which has ever been known to commerce. From Pittsburgh to Louisville, a distance of 608 miles, the Government is building 24 locks and dams. A great

and comprehensive scheme for the improvement of the Mississippi River is also under way.

Our present day demand for speedy delivery of freight and the unreliability of the water transportation heretofore provided have combined to make us indifferent to the great opportunity our rivers present for the carriage of merchandise.

This will be one of the great determining competitive factors in the near future. In twenty years the Government of the United States will have completed the slack-water navigation of the Ohio, and it will be the most perfect scheme ever conceived and executed. In all this vast distance there will be one placid stream of deep water, which will be, at most seasons, of unvarying depth. The Ohio River washes the whole western boundary of West Virginia, the Little Kanawha and Big Sandy are in process of improvement, and the Great Kanawha is already improved. All these streams reach into the heart of the state.

Coal at Colon for $3.50 per Ton

At Cabin Creek, practically the head of navigation of the Kanawha, the coal can be placed in barges at $1.15 per ton. From Cabin Creek to New Orleans is 1742 miles, from New Orleans to Colon is 1395 miles, making a total distance of 3137 miles. This distance must be contrasted with the 2159 miles from Thurmond to Colon by Newport News. It is estimated that coal will be transported from the West Virginia field to New Orleans at $1.25 to $1.50 per ton.

This West Virginia coal will be placed at New Orleans under its present conditions at a total price of $2.40 to $2.65. From New Orleans to Colon is 1395 miles and the freight is estimated at $1, thus placing West Virginia coal, at Colon, at $3.40 to $3.65 per ton.

Barges to Go Beyond Canal

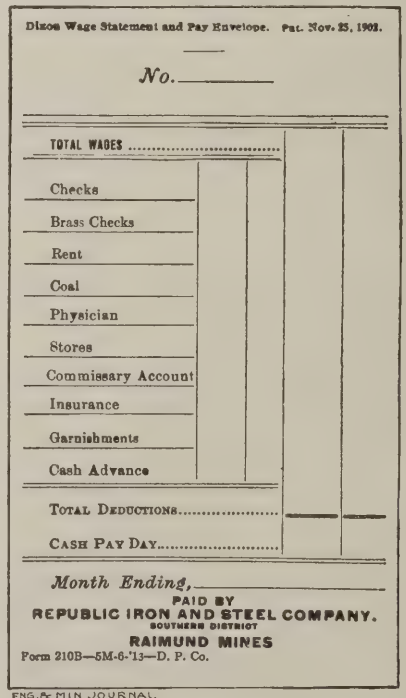
The great objection to this method of transportation and this route arises from the fact that the coal under the present system of transportation must be removed from the barges and reloaded into sea-going vessels. This is no easy matter to accomplish.

The Government of the United States, investigating this question most carefully and looking to the future development of water transportation, proposes that steel river barges, with a draft of 6 to 10 ft. and a capacity of 500 to 1000 tons will, in a few years, be introduced, and these will have the added advantage that they can be towed on the Gulf and the Carribean Sea. The coal can be transported on these barges to all ports within the market zone of the canal. The Government Commission suggests that a barge drawing from 15 to 20 ft. of water can be loaded to a depth of 7 to 9 ft. at the mines, to a draft of 12 ft. at Louisville, Ky., and for six months of the year to 15 or 20 ft., at Vicksburg, Miss.

Summary

Under these conditions, according to the Government calculations, West Virginia coal costing $1 a ton and less at the mines could be shipped anywhere to the coasts of North or South America, and sold for $3 or less per ton. Our coal at this price would drive out all others, and would be less expensive by far than the coals at the Suez Canal. This ability to ship coal cheaply to the Gulf of Mexico would be shared by the Pittsburgh field, but with an added cost of transportation proportioned to the increased distance. It is idle to say that none of the coals of Pennsylvania, Maryland and Alabama will make their presence felt in the markets of the Pacific, but it is safe to assert that the coal of West Virginia will be the over-mastering influence.

I have based my argument on the New River and Pocahontas coals, for the reason that they have been adopted as a standard for steam purposes by the Government and by those in the market. This does not mean any disparagement to the great Fairmont or the Kanawha fields.



Generally speaking, I believe that the coals of the New River and the Pocahontas regions, which are what is known as the smokeless coals, and the No. 1 or Eagle seam and the No. 2 or Gas seam of Kanawha, which are semismokeless coals, will be the fuels which will be used at the canal. This will leave the other markets, which do not need such high-grade coals, open to the great Fairmont and Kanawha splint coals, which are well suited for steam raising and gas making.

Safeguarding the Pay Roll

By A. H. Sawyer*

It is stated that an employee sometimes fails to receive his wages because someone else has previously given his name and obtained the money without question.

To guard against such practice, the Republic Iron & Steel Co. uses the Dixon patent wage statement and pay envelope; the envelope is shown herewith, the statement is a duplicate of the form on thin paper. The statement and envelope are made out in one operation by means of a sheet of carbon paper, thus avoiding any discrepancies in number, name, items or balance due.

Dixon Wage Statement and Pay Envelope. Pat. Nov. 25, 1902.

RAIMUND MINES

Form 210B—5M-6-'13—D. P. Co.

ENG. & MIN JOURNAL

Form of Envelope Duplicated on Paper Slip

The statement is handed to the employee previous to payday and is signed by him and presented to the paymaster on payday. The company is thus protected in that it retains the original statement duly receipted by the employee. The employee is also safeguarded in that he receives the envelope which is the exact duplicate of the statement which he presents to the paymaster. This seems to be as simple and efficient a system as can be devised.—*Engineering and Mining Journal.*

"Safety First"

By W. E. Holland*

Is there a slogan for all mankind?
Yes, "Safety First."
One thing we should always keep in mind
Is Safety First.
When danger comes that's beyond our ken,
May we quit ourselves like noblemen,
And give our help to each other, then,
In Safety First.

You leave your home, to the mine you go,
Then, Safety First;
To barter with danger and death below;
Again, Safety First.
All through the day your vigil keep;
Your mind alert, you must not sleep;
Or you'll have cause to wail and weep
For Safety First.

In your neighbor's place the roof is loose,
Think, Safety First.
"I'm not his keeper" is no excuse;
But, Safety First;
He may be green, knows not the way
To protect himself, or again: he may
Be bold and ignorant enough to say;
"What's Safety First?"

When you prepare your daily shot
Mind, Safety First;
To the shot firer's dangerous gambling lot
Give Safety First.
"He's being well paid," you may reply;
On his safe return his babes rely;
And he, like you, needs a good supply
Of Safety First.

Then, be a Man and take a stand,
For Safety First;
Let it be said throughout the land
There's Safety First.
Let every man, in his own mind,
Feel for himself and all mankind;
And strive with a record hard to find,
For Safety First.

Coal Production, Pennsylvania

Reports received from the second and seventh bituminous districts of Pennsylvania show the coal production and other data of interest, as follows:

Second Bituminous District, C. B. Ross, mine inspector: Advance report shows a total number of 57 mines, of which 56 are in operation; seven of these being gaseous and 49 nongaseous mines. The report shows four new mines opened and three old mines abandoned. The coal production for this district is reported as 9,037,469 tons, of which practically 81 per cent. is the result of pick mining; 5.5 per cent. compressed-air machines; and 13.5 per cent. electrical coal-cutting machines.

The total number of persons employed in the mines is reported as 5809; the total number of accidents underground, 33 fatal and 40 nonfatal accidents. There were 273,863 tons of coal produced per fatal accident underground; and 176 persons employed underground per fatal accident in the mine.

Seventh Bituminous District, Charles P. McGregor, mine inspector: Advance report gives a total of 35 mines in the district, of which 33 are in operation, 20 being gaseous and 15 nongaseous mines. There were three new mines opened during the year and none abandoned. The report shows a total production of coal, for this district, for the year 1913, of 6,271,110 tons, of which practically 82 per cent. was mined by electrical coal-cutting machines and 18 per cent. by pick mining.

The number of persons employed underground is 7266. There were 15 fatal and 56 nonfatal accidents underground. This makes the fatality rate as follows: 418,074 tons of coal produced per fatal accident; and 485 persons employed underground per fatal accident in the mine.

*Mine inspector, District No. 1, Albia, Iowa.

Short Course in Coal Mining at Colorado School of Mines, Golden, Colo.

Opens Wednesday, Apr. 1, 1914. Ends Wednesday, May 27, 1914.

The following is a brief epitome of the subjects taught:

1. MINING. Opening new areas. Use of explosives. Haulage and loading. Drainage and pumping. Power. Surface equipment. Air requirements. Dust explosions. Ventilation. Mining methods. Elementary surveying. Mining machines.

2. CHEMISTRY. Elementary definitions. Composition of air, water, and mine gases. Combustion, and chemical principles involved in gas explosions. Theory of the safety lamp. Composition of coals. Practical laboratory work on coal and gas analysis.

3. MATHEMATICS. Weights and measures. Arithmetic, from ground rules and decimals to ratio and proportion. Simple physical problems, elementary algebra and use of logarithms. How to use the formula commonly required in coal mining.

4. MECHANICS AND DRAWING. A short course in mechanics, drawing, mapping, and the use of instruments.

5. GEOLOGY. Elements of geology, with special reference to coal deposits, with laboratory work on rocks, supplemented by short trips in the vicinity of Golden.

No fees for instruction. In the laboratory, material actually consumed will be charged for, also two or three textbooks, total expense not to exceed $5.

The course will materially aid candidates for positions in coal mines to pass the required state examinations under the laws regulating coal mining.

For further information address Wm. G. Haldane, acting president, Colorado School of Mines, Golden, Colo.

A New Byproduct Coke-Oven Installation

The H. Koppers Co., of Chicago, have recently closed a contract with the Lehigh Coke Co., a subsidiary of the Bethlehem Steel Co., for the construction of what is claimed to be the second largest byproduct coking installation in the world. The plant will consist of over 400 ovens, and will consume 6000 tons of coal per 24 hr. The construction will continue about two years, and will provide for the dismantling and rebuilding of a portion of the present installation which has not proved satisfactory. The approximate cost of the work is estimated at four million dollars.

Care must be exercised, in coal mining, to see that all stoppings are promptly and properly made and canvas curtains hung as soon as required, and that they are always kept in proper condition.

Important Details in Construction of Colliery Plants

By M. L. Hyde*

[This Article Is Unusually Long for Presentation in a Single Issue of Coal Age. However, the Subject Is One that Will Interest Most Coal Men, and Is of a Character that Will Appeal to Many for Filing Purposes. We Are, Therefore, Printing the Entire Article in One Installment, Believing that Such a Plan Will Best Suit the Convenience of Our Readers.—Editor.]

SYNOPSIS—Practical suggestions concerning the erection of an entire colliery plant. A plan for laying out the organization is given. Complete equipment of the various buildings is enumerated, and a method of handling the coal is described.

The rapid strides being made in our coal-mining industry place us all in a position where at any moment we may be called upon to undertake the construction of a new plant, and I have prepared this paper in the hope that it may be of some service to those who must meet the many complex problems such a task imposes.

After the property has been purchased and a plant site and tonnage capacity decided upon, the most important details in their order are:

1. The estimate of construction and operating capital required to put the plant on an operating basis. Few of us are familiar with estimating, and we either rely on consulting engineers who do not face the directors if the appropriation is inadequate, or we do the work ourselves; in either case we usually regret our choice, for detail after detail usually looms up that has been overlooked.

2. The plan of underground layout showing method of winning coal, ventilation, haulage systems, etc. Concerning these details, the practical operator is presumed to be well informed; further, the conditions are so varied as to be far beyond the scope of a paper as short as this must necessarily be.

3. The plan of surface layout showing relative location of mine openings, railroad yard, plant buildings and townsite. If construction and operating costs are to be kept a minimum; the modern colliery must have its plant concentrated and equipped with labor-saving machinery wherever practicable to do so. Particular attention will therefore be given the most important details coming under this division.

Estimating the Cost

In order to make an estimate cover fully the problems presented, we must arrange a basis on which to work. I would suggest that each unit be figured under three separate subdivisions, namely, improvement, equipment and operation.

An improvement account should represent the permanent, immovable unit; comprising, in the case of a building, the excavations, foundations for building, foundations for all machinery in said building, the building proper including all materials and labor going into its makeup, as concrete, brick, steel and woodwork, windows, doors, roofing, painting, light and phone wiring, heating and water piping, hardware, etc.

An improvement account in the case of a mine would represent the actual cost of bringing the mine to a given capacity in a given time; including the sinking of shafts or slopes, entry driving, sufficient room necks for the required capacity, all permanent timbering, ditching, sumps, overcasts, doors, regulators, stoppings, underground shops, office, underground storage for both empties and loads, all light and signal wiring and the labor in laying all permanent haulage tracks and power wires.

An equipment account should represent the more or less permanent yet removable units.

In the case of an office, we must figure on the lighting fixtures, furniture, typewriters, phones, safe, stoves, filing cabinets, etc.

In the case of a shop, there are the motors, transmission machinery, machine tools set on foundations, permanent small tools, such as dies, etc., that are stamped and must be accounted for in the inventory, tool-cabinets, lockers, etc.

In the case of a mine, we must consider the signal and phone apparatus, enameled signs, mine cars, locomotives, animals, mining machines, shot-firing magnetos, drills, pumps, motors, steel rails, ties, power and trolley wire, steam and water-pipe lines, car-hauls, etc.

The Operating Account

An operating account should represent the materials used in operation and of a less permanent nature than those in the equipment account.

In the case of an office, we have the heating coal, stationery, postage, lamps, printed forms, books, salaries of office force, porter, etc.

In the case of a shop, there are forge coal, bits, all small tools, oil, waste, lamps, wages, etc.

In the case of a mine, operation charges must cover the cost of timbering after the improvement period is closed, the cost of mine ties, spikes, brattice cloth, lamps, all wiring except permanent power and trolley, trolley hangers, etc., powder, tamping cartridges, tools, machinery upkeep and replacing of broken parts, all wages for entry driving, timbering, etc.

During the construction period covered by the estimate I should figure all of the accounts as operating, for example; the power house must manufacture power for running the shop, fan, hoist, etc., yet in the end it is doing so for the benefit of the mine improvement account, and the operating of all such units should be figured up for the time allotted for the construction of the mine, and then charged proportionately to the different improvement accounts enjoying them.

Laying Out the Organization

We should now lay out the organization required, and the wage cost of maintaining its officials or unproductive labor, as follows:

Mine Manager, to act as general supervisor, engineer

*General manager, Pembina Coal Co., Entwistle, Alta.

Note—A paper presented to the Canadian Mining Institute, February, 1914.

and surveyor, and to handle all mine construction. His employment should commence at an early date so that he may become familiar with every detail of the plant.

Master mechanic, and two or three erection assistants, all familiar with erection and pipe fitting. Under him will also come engineers, firemen, blacksmiths and pumpmen.

Chief electrician, and two or three erection assistants, all familiar with erection and wiring of electric machinery.

Surface foreman and gang of laborers familiar with grading, tracklaying, etc.

Tipple boss and gang of coal cleaners and yard men.

Boss carpenter and gang of erection, heavy- and light-framing carpenters.

Stable boss and drivers, to handle the stable and teams.

Accountant in charge of office, to handle books, cash, etc.

thaw house if dynamite or monobel is used, washroom, foreman's office, ventilating plant, narrow-gage tramroads for local transportation of supplies, and water and lighting systems.

Next, the cost of all permanent plant improvements with their equipment and operating costs during the construction period; including railroad yards, track scales, mine opening with shafts or slopes, boiler room with coal bins and conveyor, ash-handling cars, ash skip and bin, hoist-engine room, engine-room change house, supply room, machine shops, man-hoist engine room, tipple, mine office, pipe and bar-iron rack, oil house, man-hoist headframe, fan, water tank, mine closet, fire-hose reel shed, lamp room, powder magazine, thaw house, yard-track system, water, lighting and drainage systems, fencing, signs, engineering equipment, outside power and pipe lines, etc.

Then the cost of all townsite improvements with their

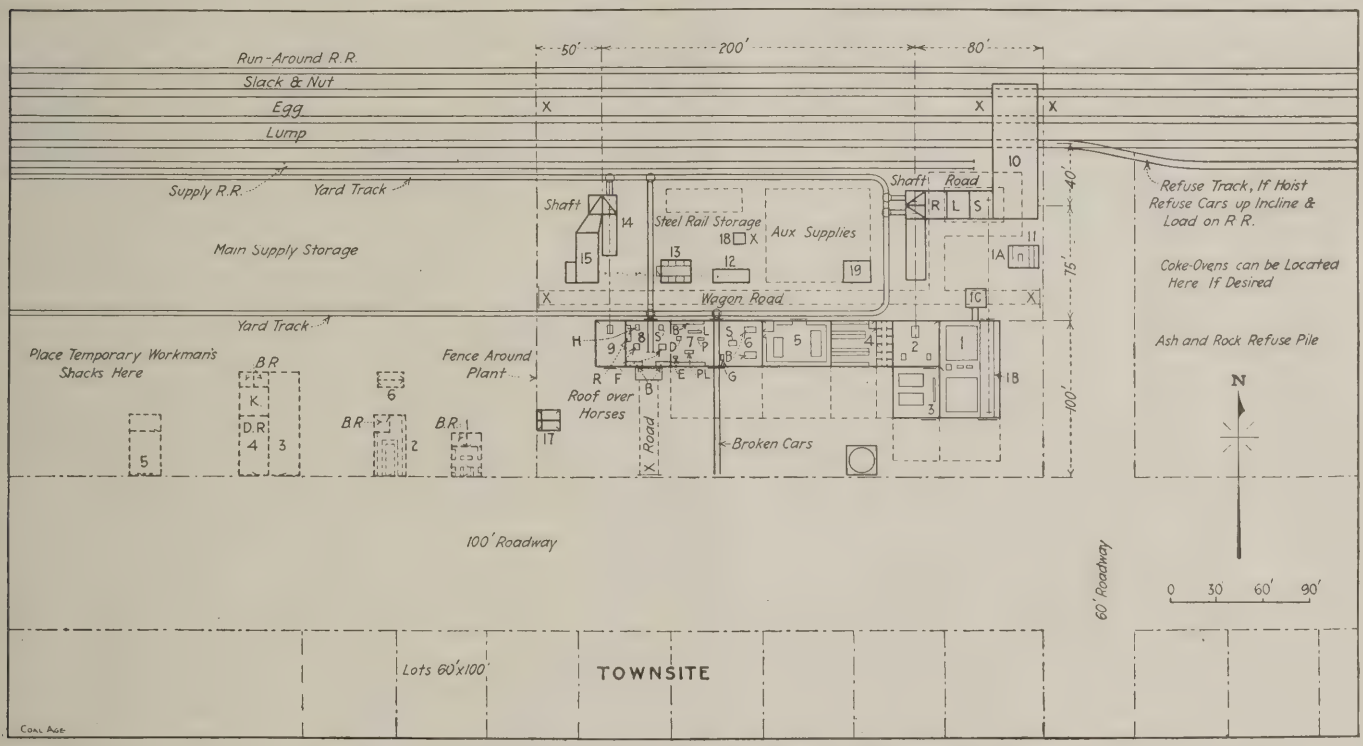

FIG. 1. A STANDARD DESIGN FOR MODERN COLLIERY PLANT

Payroll clerk to handle payroll, correspondence, filing, etc., and under him a time clerk to keep the distribution of wages.

Supply-house foreman, to check and store all incoming supplies, issue supplies, keep record of stock on hand, distribution of supplies issued, etc.

Store manager and clerk in charge of the store, its purchases, etc.

Arrangements should also be made to have a doctor give part of his time to the colliery during construction.

Next comes the cost of clearing and grading the property; this needs no comment.

COST OF TEMPORARY UNITS

Then the cost of all temporary units to be used during construction with their equipment and operating cost, also the cost of tearing them down, less value of material salvaged. The temporary units usually required will include an office, store, cook house, bunkhouse, stable, closet, power house, supply room and shop, oil house, equipment and first year's operating, less receipt from rentals, including main office, store, hotel, club house, hospital, school, church, officials' homes, tenements, outhouses, lighting, water, drainage and sewer systems, fencing, sidewalks, streets, etc.

Then as a last consideration, there are miscellaneous requirements, such as the expense account covering fire and workmen's compensation insurance, hospital fees, traveling expenses, coal analysis, advertising, litigation, phone and telegraph service, entertainment, personal expenses, etc. The working capital account covering selling costs and freight charges on at least two months' shipments, during which time no returns can be anticipated, must also be allowed for.

Before going further, underground and surface layouts will be required, and in their completeness lies our protection in the accuracy of the estimates.

The underground plan should show the proposed development of the entire plant in rough and the work to be done during construction in detail.

The surface plan should show the relative position of the mine openings, all temporary and permanent plant improvements connected with the operation of the mine, and the townsite layout.

I believe that most mines having a daily capacity of 500 tons or over can be brought, so far as the plant improvements are concerned, to a standard design more or less approaching that shown in Fig. 1. This covers a shaft mine of one to two thousand tons capacity; but, with small alterations, such as the location of the fan, the layout is applicable to either drift or slope mines, and with increased or decreased size of building to any capacity mine.

The drawing is self-explanatory, showing the townsite located either to the north or south of the plant to avoid our prevailing west winds carrying boiler-room smoke over the houses; also located close enough to the plant that long walks to and from work are eliminated and so that no employees or children need cross the railroad yards.

The temporary units are set near the plant but so as not to interfere with the construction of any of the permanent improvements and yet allow of a minimum amount of land being cleared.

The permanent units are set along the line of yard tracks: this allows the railroad-grading contractor to grade the site at the same time as the yard. The location also allows of all supplies and heavy machinery being unloaded to the best advantage. Machinery for the mine can be sent down with the one handling and power-plant and machine-shop units unloaded direct to yard-trucks and skidded from them to their foundations.

A railroad yard approximately 330 ft. long by 235 ft. wide will be all that is required by the average mine. This can be fenced with a high galvanized wire fence on three sides, and none but employees on duty allowed through the gates. A fire-hose shed placed central with reels carrying 300-ft. lengths of hose will protect every unit. A night watchman can visit every unit and the storage yards at short intervals. Every person entering or leaving the gate is under observation from the mine office. The problem of lighting, drainage and sewage is a very simple one. All refuse from tipple and boiler room can be stocked along railroad tracks or loaded to cars at a minimum expense, and in case the piles should catch on fire, the flames and fumes would be carried away from the plant and town. I would mention that to make this layout entirely satisfactory, either fireproof or slow-burning construction must be used.

The Various Surface Improvements

Passing to the details of the various surface improvements and their equipment, we have first, the temporary structures. These are required to get the working organization in shape as quickly as possible and must last at least one or two years. The buildings should be cheap and built of standard dimensioned lumber that can be easily salvaged. The equipment can, in most cases, be permanent, and later transferred to the permanent improvements; for this reason their location should be as close as possible to said permanent unit.

Flat roofs will give best results and a standard width of 20 ft. can be established, with walls 10 ft. high on one side and 9 ft. on the other as per Fig. 2. They should be set on posts, one foot off of ground to avoid the necessity of drainage ditches around them, and should be

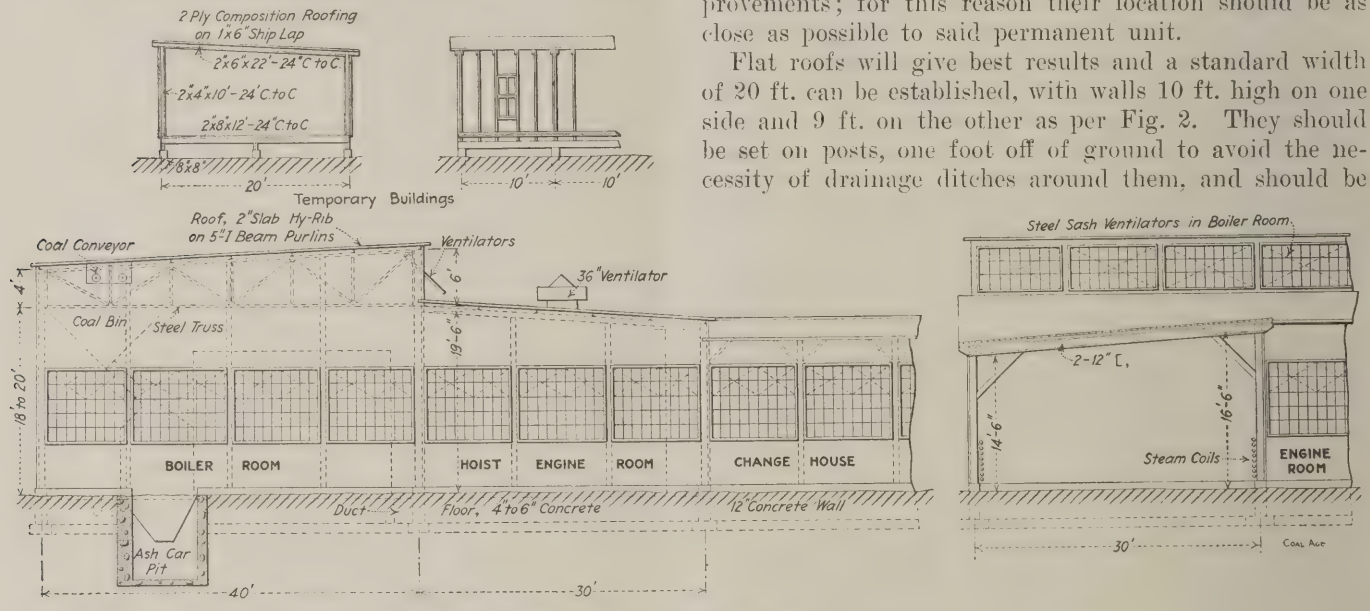

Fig. 2. Construction Details of Temporary Surface Buildings

constructed entirely of 10-, 12- and 14-ft. lengths of 2x4-in., 2x6-in., 2x8-in. and 1x6-in. shiplap sheathing, one-ply building paper and two-ply composition roofing. All studding, sheathing and siding should be driven light with short nails. Both bunk and cook houses should be lighted from the roof, by rubber glass skylights: the cost is less than windows and the lighting better.

A Temporary Office

A temporary office should be about 20x30 ft. For equipment, it should contain superintendent's desk, two high desks and two low desks, one each for accountant and payroll clerk, two stools, six chairs, safe, stationary cabinet, stove, filing-system cabinet, drawing table, typewriter, telephone, fire extinguisher, engineering equipment including transit, drawing instruments, etc., for which an allowance of $1000 should be made. First-aid equipment, including pulmotor, first-aid cabinet, stretchers, medicines, etc., for which at least $350 should be allowed.

As to operation, we must consider salary of force during construction, including superintendent, payroll clerk, time clerk, draftsman, watchman, porter, stationery, supplies, heating coal, and an allowance of at least $2000 for printed forms covering departmental reports. In the

back of the office should be two 10-ft. square bedrooms, furnished, one for superintendent and mine manager, and one for office force. This furniture can be transferred to the hotel later and should be permanent.

The Company Store

The company store should be 20x40 ft. The equipment should consist of manager's desk, chair, cash register, scales, stove, fire extinguisher and telephone, all permanent. As to operation, there are salary of manager and clerk for three months, and $5000 allowance for stock. After this period, the store receipts should cover its operation.

In the back of the store should be a 10-ft. square bedroom for the manager and clerk, fitted with permanent furniture.

Other Buildings

Cookhouse—Size, 20 ft. wide by 70 ft. long, 40-ft. dining room in front. Equipment: 2 stoves, 2 tables and 4 benches. Kitchen, 20 ft. square. Equipment: Range, sink, table, counter, chairs, fire extinguisher and $500 allowance for utensils, dishes, etc. The range and dishes being permanent. Two rear bedrooms 10 ft. square with double bunks, two chairs and table in each, should be furnished for the cooks. Operation: This building should at once be rented to a reliable man and his wife; under no conditions should the company attempt to run it during construction.

Bunkhouse—Size 20 ft. by 70 ft. Equipment: Twenty to 40 double-deck, 2-ft. 6-in. wide by 6-ft. 6-in. long steel-spring bunks with cotton pads, 2 stoves, 2 tables, 4 benches, 2 wash sinks, and fire extinguishers. Operation: This building should be under the same people controlling the cookhouse. Attention is here called to a double-deck bunk made by Haggard and Marcusson, of Chicago, consisting of 2 steel spring cots set one above the other on a frame work of steel angles, and costing approximately $7 delivered, plus $2 for the pad or $4.50 per man. This makes a strong sanitary bed, economical in space and one that can afterwards be used in the hotel or company boarding house. Wood bunks with straw are one of the most serious vermin and disease breeders in a construction camp and I strongly recommend the additional expense required for the steel ones. They can also be used in the office, store and cook-house bedrooms.

Stable—Size 20 ft. by 40 ft. This will house 4 to 6 horses and a carload of hay and grain. Equipment: Wagons, sleighs, horses, harness, blankets, fire extinguisher, etc. Operation: Wages of boss and drivers, repairs, shoeing, feed, etc.

A water closet with private compartment for officials should be placed near the bunkhouse and operated by people running same.

Laundry—A small shack should be built and equipped with stoves, copper boiler, etc., for this purpose. It should then be rented to a Chinaman and an understanding had of the prices to be charged; invariably much trouble is experienced during construction in this quarter.

Pig Pen—The disposal of garbage is a serious item and a dozen pigs will prove the most desirable outlet. These can be kept by the stable boss and sold through the store to the cook house.

Temporary Buildings at Mine

Foreman's Office—Size 12 ft. by 20 ft. Equipment: Desk, drawing board, high desk for time keeper, table, chairs, phone, stove and fire extinguisher.

Shop—Size 20 ft. by 20 ft. Equipment: Forge, hand blower, hand drill press, swage blocks, mandrels, stove, fire extinguisher, etc. Operation: Wages of blacksmiths and machinists, small tools, blacksmith coal, oil, etc.

Supply House—Size 20 ft. by 20 ft., and forming extension to shop. Equipment: High desk, stool, stove, phone and fire extinguishers, also stock of repair parts for machinery, packing, hardware, picks, shovels, rope, tackle, wire, etc., also yard stock including mine props, ties, rails, trolley wire, bar iron, square timber, building lumber, mine-car lumber, bricks, lime, cement, gravel, etc., also oil-house stock, including all oils, grease, etc., and lastly powder-magazine stock, including explosives, detonators, squibs, etc. From $10,000 up should be allowed in estimate to cover this stock. Operation: Wages of foreman, freight, express and handling of supplies.

Miner's Washroom—Size 15 ft. by 20 ft., and forming extension to supply house. Equipment: Stove, wash sink, benches and fire extinguisher. Operation: Wages of keeper, heating fuel, soap, etc.

Boiler Room—The size of this building will depend on whether or not shafts are being sunk requiring compressed air; if not, hoisting engines with boilers attached, will be all that is required for erecting tipple and main building, in which case no boiler room will be needed. If shafts are to be sunk, a 60- or 70-hp. vertical boiler is easily salvaged and fills all requirements nicely. With this unit should be estimated such hoists, compressors pumps, drills, and other miscellaneous machinery as will be required during construction. Operation: Wages of firemen and engineers, cost of fuel, water, oil, waste, removal of ashes, etc.

Estimate must also cover cost of sinking well for water-supply, also ditch and pipe line.

Each of the above mentioned units except boiler room can be built inside the lines of the permanent foundations of main building and when this is roofed they can be torn down and their equipment replaced in permanent structure at small expense. The boiler room should be located on a line, and central with the two shafts, and sinking engines placed on each side of boiler.

The temporary oil house and thaw house or powder magazine, will be merely shacks and require no special mention.

Outside Tramroads—It may be necessary to handle supplies a considerable distance from railroad station until yards are put in. In this case a tramroad of 16-lb. rails should be estimated on, also a given sum for its operation.

Tipple—This will vary according to location of mine opening and no details can well be given here. From shaft mines, all material, during sinking, will be handled over temporary headframes, and from drift mines a chute with bar screens will fill all requirements. This structure with equipment and operation including cleaning of coal, removal of waste and handling of railroad cars should be carefully estimated on.

Outside Lighting—Several large Milburn type carbide lamps will be required, also carbide for their operation.

The above units cover all temporary work required and as soon as supplies are on hand, the construction of both

the temporary and permanent plant can commence. The clearing of the property should be done in April, the grading in May, and the permanent building from June to November.

Permanent Units

The tipple equipment should include cages, head sheaves, ropes or car hauls or conveyors, dump hopper, bar screens, weigh pan, scales, inspection table, shaker screens, picking tables, chutes, boxcar loaders, motors, transmission machinery, phone, tally boards, signs, fire extinguishers, etc.

In designing this unit we have one of four different mine-opening conditions to meet. First, where the opening is above tipple dump requiring either retarding conveyors, gravity planes, tramroads or carhauls. Second, where opening is on approximate level with tipple dump requiring either locomotives or rope haulage. Third, where opening is below, requiring either engine planes, incline-conveyors or car hauls. Fourth, where seam is directly below, requiring cages and a headframe.

Conveyors Can Be Used Advantageously

Under conditions number one and three, conveyors can be used to best advantage where a capacity of 100 tons per hour or more is required, having the following advantages over lowering or raising mine cars on planes: They eliminate one man at the head of incline who handles the lowering machinery and at least one man at the foot; they have a capacity far greater than can be obtained from either cars or monitors on planes; and, running in a covered truss, are not subject to damage from storms as are open-track layouts and fewer mine cars are needed, as the length of time the car is kept out of the mine is much shorter.

Whether the conveyor drags, retards or carries the coal, there is absolutely no breakage during transit, and, where the scraper type, dragging coal on the bottom strand, is used, there is a perfect discharge to the tipple screen. so that in comparison with delivering the mine cars direct to the tipple and dumping the coal but once, the advantage is in favor of the conveyor.

The tipple should be a steel structure of minimum height, equipped with self-dumping cages, if a shaft mine, and should have the ability to load in either open or box-cars any sizes the market may demand or any combination of such sizes. It should have a bin in which rock can be dumped direct without having to pass over any of the coal-sizing machinery with the extra wear imposed due to its gritty nature. Next should come a bin for run-of-mine to be sold locally, this should also be arranged so that the coal does not have to pass over the sizing machinery as it must be sold at a close price to employees and homesteaders. Next to this should come a slack bin delivering either to wagons or to a conveyor which feeds boiler-room coal bins.

Fig. 3. General View of Tipple Building Showing Refuse Bin and Location of Picking Table

Method of Handling the Coal

Coal for market should be dumped direct to a hopper and from this should flow to an apron conveyor 5 to 6 ft. wide by 20 to 25 ft. long; this acts primarily as a feeder delivering the coal in a uniform stream to the screens; it acts also as an inspection table where the checkman can see from his office the entire carload spread out and traveling at a very slow speed. He can, furthermore, stop this feeder with a given load of coal on it and pick out and weigh the rock in case of a dispute between himself and the miners' representative. In screen-coal mines, the coal should flow from dump hopper over a bar screen to weigh pan and thence to above feeder.

From the feeder the coal passes over a short chute fitted with a butterfly valve to allow of its being dumped direct to local coal bin or with this valve closed to a shaker screen 5 to 8 ft. wide, by 25 to 35 ft. long, depending upon capacity desired.

In case of clean coal, this screen can lead direct over the different loading tracks, or a Marcus-type screen can be used to even better advantage if the coal is dry.

Where the coal is dirty and requires hand cleaning, I would in most cases recommend the following path from feeder, assuming four grades of coal are required: On entering the shaker screen, the coal should pass first over the nut perforations through which both nut and slack drop on to a slack screen, which should always be of the Cross Patent Lip type, consisting of 12-in. long slots set in rows with a 1-in. drop at the end of each; this tends to continually turn the coal over and bring the fines on the bottom. These slots are wider at the bottom than the top and are, therefore, self-cleaning. This screen is the best for slack, because in most seams carrying dirt bands, they usually break in thin lenses that will not go through round holes small enough to keep oversize coal out. The slack passing through cross screens goes to a slack bin and thence to boilers; or the screen should be so arranged that it can be blinded and the slack allowed to flow on to railroad cars.

The nut passing over the slack screen should go to a conveyor running at right angles to the shaker and there be picked and afterwards discharged to railroad cars on any track.

The lump and egg passing over the nut screen are separated on an egg screen and each is sent to a conveyor on which they are picked and then discharged to any of the railroad tracks. The different chutes should be so arranged as to gather from any of the three conveyors, and by this method any size or combination of sizes can be loaded on any track.

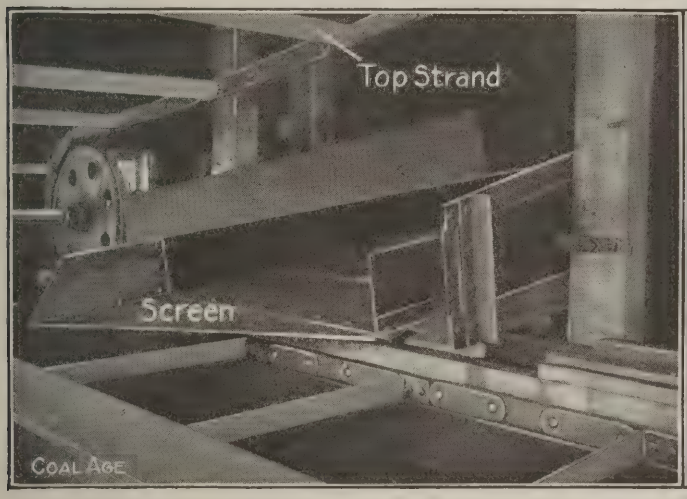

FIG. 4. INTERIOR TIPPLE VIEW SHOWING LIP OF SCREEN AND PICKING TABLE

FIG. 5. ANOTHER VIEW SHOWING WHERE LUMP, EGG AND NUT COAL ARE PICKED

DETAIL OF CAGES

I would recommend in most cases self-dumping cages with dumping rollers at top of dumping platform as greater leverage and consequent reduced strain on both cage and headframe is secured. The cages should be designed to allow the car to project beyond ends of cage, so that in a dumped position, the car would be lifted the minimum distance above apron, insuring a small drop to friable coal and no spilling down the shaft. The guide irons should be so curved that during the dumping period the car is rapidly dropped to the dumping position and while dumping is moved very slowly. Horns are preferable to drop rails for rapid work. Detaching hooks and double bridle chains should form part of the equipment of every cage. Wood floors are preferable to steel, being lighter and less slippery.

The prime reason advanced by the advocates of platform cages and the automatic pushing of the cars from same to cross-over or rotary dumps, is the question of saving in breakage. With the cross-over dump there is none, and with the rotary not enough to warrant the excessive extra cost of the tipple, extra cost of power to operate pushers and empty car hauls, and wages of at least two extra men in handling cars to dumps. In fact with our modern self-dumping cages, I do not believe a rotary dump can do the work as quickly and with as little breakage.

DETAILS OF SHAKER SCREEN

The shaker screen should be of the single unbalanced type in preference to two screens working in so called balance. This statement will probably create much dissension, but a single screen driven by connecting-rods from oval-faced eccentrics keyed on an eccentric shaft, which in turn is carried on an independent framework from the tipple structure, will not put as much vibration in the tipple as a pair of screens. We have now in operation in a wooden structure an unbalanced screen 34 ft. long of the double-deck hanger type. This screen has a capacity of 150 tons per hour and makes four grades of coal. It has given us no trouble from vibration whatever, in fact, far less than I have experienced from carefully designed balanced screens carried on an independent steel framework figured with a fiber stress of but 4000 lb. The single screen costs but little more than half as much as a pair of screens and dischargs over much simpler chutes to the different conveyors.

In designing these screens, there should be a bearing on each side of each eccentric, the eccentric should be fitted with spring compression grease cups so that in case they tend to heat, more oil will be fed. The driven pulley on the eccentric shaft should in all cases be fitted with

a friction clutch for starting and stopping. No plates should be less than one-quarter inch thick and no reinforcing angles less than five-sixteenths of an inch.

Details of Picking Table

Figs. 3, 4 and 5 give an idea of the arrangement and operation of the picking table. Each table should lead from the screen over all tracks; each should have an independent motor drive and friction clutch for starting and stopping. They should be of the scraper type with a double strand of steel bar link chain carrying steel cross bars, of the same depth as the chain link, at 24-in. intervals. A strong and satisfactory picking table is made up of two strands of chain having 3-in. by ½-in. by 12-in. pitch links, 1-in. pins, 3-in. by ½-in. crossbars, 48-in. sprockets, and a speed of 40 ft. per minute. The coal is carried by the bottom strand on a ¼-in. steel trough, and discharged through openings to hinged chutes over the tracks. All picking is done on the 25 ft. or over length between the screen and the inside railroad track; the refuse bins being below the floor of this room and discharging to wagons, cars or conveyors, as shown in Fig. 3. The return strand travels back overhead on guide rollers.

This conveyor carries the coal as uniformly spread out as does the apron type; is fully as easy to pick from and can discharge all or part of its contents at any number of openings with a minimum breakage; the cost is much less, and but little more power is required to operate it; also, less headroom is required and a less expensive supporting structure is needed. With the apron conveyor, coal can be carried on the top strand only and discharged at one point only, over the head sprocket.

With this tipple construction, the bottom strand of conveyors need clear railroad tracks by but 18 ft. It is, therefore, an easy problem to design chutes for loading open or box-cars with but little breakage.

For loading box-cars with coal under 6 in. in size, the Ticknor Manierre loader made at Milwaukee is the cheapest in first cost, requires the least power and loads with the least breakage of any loader that I know of on the market. It has a further advantage in that one loader placed between two tracks, 19-ft. centers, can load cars on either track. For lump coal, I believe the Christy made at Des Moines, to be one of the most satisfactory.

Main Plant Building

The main plant building should be located as shown in Fig. 1. It should be so designed that extensions can be made in any department at a minimum cost and should preferably be fireproof and of a skeleton steel type with brick, or Hy-rib cement-plaster walls. A wooden frame with corrugated iron siding and partitions serves the purpose when first cost is a strong factor, being practically fireproof. The roof of this building should be nearly flat and made up of 2-in. Hy-rib on 5-in. I-beam purlins or 2-in. by 4-in. tongue-and-groove, kiln dried mill flooring with Barrett Specification Roofing, if the cheaper type is used. With this construction the building is easily heated, lighted, ventilated, cleaned, inspected and protected from fire.

At the tipple end comes the boiler room with hoist engine and engine room back to back against it, giving a most economical steam piping layout and allowing of extensions as desired. Next come the miners' change room, supply house, carpenter shop, machine shop, blacksmith shop and lastly the man and material hoist-engine room.

Boiler-Room Equipment

Boilers, stokers, draft equipment, stack, etc., must be included in the boiler-room equipment. For feeding boilers, slack coal will be brought direct from tipple by a wire-rope conveyor. Ashes will be handled in side-dump cars running in a tunnel underneath the boilers and discharging to a hopper leading to an ash skip, which in turn discharges to an ash bin from which the ashes are drawn to a wagon on the same street and at close proximity to the point where refuse from the tipple bin is taken.

Water-tube boilers should be installed in units of from 200 to 300 horsepower, and of not less than 150 to 175 lb. steam pressure. "Safety First," economy, and low first cost are conserved by their use. A rupture in any given tube is purely local and causes no serious damage, while with a return-tubular type an explosion would be the result. They are about 15 per cent. more economical in fuel and require approximately but two-thirds the cubical boiler-room space. The first cost of the plant installed will also be less.

No recommendations can be made relative to stokers as each coal requires special consideration. The fact that a good stoker will burn low-grade slack, eliminate smoke, and reduce the cost of fire-room labor usually warrants its installation.

With low-grade fuel many advantages are offered by an induced-draft system, since it is cheaper in first cost than a chimney and allows thick fires with strong drafts, thus promoting complete combustion.

Hoist Engine-Room Equipment

In the hoist-engine room, we must consider the main hoist, signals, phones and overwinding device. A Corliss hoist requires approximately 43 lb. of steam per horsepower and a slide valve 50 lb. or more, showing a saving of at least 15 per cent. in favor of the former. Exhaust steam may be used, but the greater first cost would keep this plan from being a profitable investment. Electric hoists are very expensive, and not warranted directly at the power plant, where low-cost fuel and mixed-pressure turbines can be used.

Engine-Room Equipment—If electricity is required, the mixed-pressure turbine-driven generator will prove most satisfactory and by storing exhaust from hoist in regenerators will allow of manufacturing power at no cost outside of upkeep. The turbine excels a reciprocating engine on account of the expansion which can be given to the steam at low pressure. At high pressures, the high-class reciprocating engine is more economical, but the advisability of installing both types of units in a new plant is a question.

If compressed air is required, the high-speed vertical compressors are very economical and generally satisfactory, and furthermore require but small floor area.

In addition, there will be required in the engine room, a switchboard, tool and clothes lockers, fire extinguishers, phone, desk, and boiler-feed equipment, including pumps and heaters. An open heater adds approximately 16 per cent. to boiler efficiency and therefore saves that much handling of coal and ashes. Closed heaters are not recommended for mine work. They are under pressure,

subject to temperature strains, hard to clean, do not save the exhaust condensed in doing the heating, and make no provision for the settlement of solids. Turbine-driven centrifugal feed pumps in duplicate complete the equipment with the most efficient and fool-proof machinery to be had.

Change-Room Equipment—Benches, clothes hangers, wash basins, shower baths, supply cabinet, fire extinguishers, etc. One shower bath should be allowed for every 25 employees.

Supply-Room Equipment—Shelves, bins, scale, phone, fire extinguishers, etc. This building should have a small office for a supply foreman.

Carpenter-Shop Equipment—Two benches, combination saw and grindstone.

Machine-Shop Equipment—Two benches, open-gap lathe, pipe machine, with set dies for making bolts, planer, large power-driven drill press and emery wheel.

Blacksmith-Shop Equipment—Two forges, 200-lb. power-driven hammer, combination hand punch and shear, two benches and pipe rack for local supply of bar iron and pipe. A 25-hp. motor with transmission machinery will be required for driving tools in all three shops. There should be a roof furnished over the back door of blacksmith shop, that horses waiting to be shod may be kept under cover.

Man and Material Hoist-Engine-Room Equipment—Steam or electric-driven geared hoist with phone and signal apparatus and overwinding device.

In the general arrangement of this building it will be noted that mine cars can be brought in for repairs over a minimum length of track from either shaft and that all supplies are carried near the shop where required.

The location of the other permanent units is clearly shown in Fig. 1. These can all be built at a moderate cost, using either skeleton steel or wood with cement plaster. The pipe and bar-iron rack can be built of 3-in. piping with standard fittings. No mention will be given the equipment of these various units except the oil house, which should have Bowser or equal self-measuring two-barrel tanks for every grade of oil used.

Steam heating will be required in the tipple, main plant building, mine office, oil house, lamp room and water tank; fire extinguishers should be placed in every room in every building, also buckets of sand wherever electrical machinery is in use.

The distribution of outside lights, layout of roads, yard tracks, etc., is clearly shown and their cost easily estimated. Care must be taken to cover the cost of outside power lines including poles, wiring, etc.; outside pipe lines, including supports, piping, covering, etc.; outside water lines, including ditching, piping, hydrants, etc.

Townsite Units—The design and estimating of the units will be taken up by themselves in a future paper, meriting as they do a special discussion.

Before closing, I want to give a few hints on purchasing the plant.

We have three choices before us. First, the manufacturer who maintains an engineering department, specializing on one or more of our wants, and who, free of cost, will make plans to cover all requirements. Such a manufacturer will also bid on the business against all competition, and, if successful, will be personally responsible, rectifying all errors without any additional charge. Second, the contracting engineers who either agree to build whole or part of the plant for a fixed sum, or cost plus either 10 or 15 per cent. These concerns usually have superb engineering organizations and good salesmen, but they must in turn buy everything from the manufacturer above mentioned, and in turn place the responsibility on him, nor can they buy cheaper in competition than ourselves. On a lump-sum basis, contracting engineers can, and often do, save their clients considerable money and a great deal of worry through his dealing with one responsible concern only, but so far as a "cost plus" basis is concerned, I can see nothing to recommend it in this class of work for we must stand the brunt of all mistakes and pay a commission on them besides. Third, we can build

FIG. 6. SHOWING COURSE OF COAL THROUGH TIPPLE

our plant, or part of it ourselves. I would recommend doing the work part under condition one and part under condition three.

THE TIPPLE BUILDING

In the matter of building the tipple, I should ask the Link Belt Co., the Jeffrey Manufacturing Co., Head Wrightson, Ltd., and one or two others of that class to send their representatives, which they do without cost, and have them go over the ground. I would then carefully analyze all suggestions and give each company a general idea of the requirements, requesting plans and bids. Any of these concerns could also erect the main plant building, water tank, fan and track scales at the same time the tipple was being put up.

Machinery in Main Plant Building—I should ask the reputable boiler people, such as the Babcock and Wilcox Co., The Stirling Co., The Waterous Co., and one or two others to make plans and specifications covering the boilers, heaters, pumps and steam and water piping. I would also make arrangements for the use of their erector to place all heavy machinery such as engines and generators; the latter being purchased in competition from any of the reliable concerns.

The shop machinery with its transmission can be purchased complete from such firms as the Canadian Fairbanks Co., Ltd., Mussens, Ltd., etc. These people will gladly make, without charge, a layout for setting the different units; and their erection I should leave to my master mechanic, who can also erect all heating piping, etc. All wiring and erection of motors can be done by the chief electrician. All building of the temporary and

small permanent units by the boss carpenter, and all clearing, ditching, etc., by the surface foreman.

The grading of railroad yards should be let complete, including the placing of ties, laying of steel and switches, to a contractor specializing in this work and having the necessary teams, scrapers, camp equipment, etc., to do it; also one capable of putting up a bond.

For designing the small units and doing general drafting work, I should borrow a draftsman from the people furnishing the tipple, returning him at the end of the construction period.

Finally, after the estimate is made complete and covers every unit with its equipment and operation, at least 15 to 25 per cent. should be added for protection, in covering the many details that will still crop up.

Safety Requirements

By A. L. H. Street*

SYNOPSIS—An inquiry in reference to the legal performance of his daily duties by the mine examiner when he fails to report a miner's working place as dangerous and as a result the miner is badly injured by a fall of rock in his place. Another inquiry, asking if a mine is worked in compliance with the law when a night shift of miners is permitted to enter the mine and dig coal when no night boss is present and no one has charge of the mine.

An Illinois miner asks advice concerning the duties of Illinois mine managers and examiners, as follows:

1. There being a bad roof in a working place, the mine examiner took the miner's check, marked the miner out, marked the roof for loose rock and entered same on his report. The room was timbered that day and the miner worked the following morning, when the same conditions existed but were not reported by the examiner, and the presence of loose rock was not marked that day. Entrance checks were not held nor was the place marked off. The miner was injured before he could remove enough coal to place props to secure the roof. The place not being marked out and checks not being held, the miner, presumably, believed that no immediate danger existed. Did the mine examiner violate the law by not holding the miner's check and by not marking each day the place where dangerous conditions existed?

2. The mine is worked by both night and day shifts, but no one is in charge of the night shift. Is this mine being worked in compliance with the law?

1. That the Illinois coal-mine law was violated on the facts above stated appears from the following abstract of provisions of the law as found at pp. 430, 431 of the 1913 Session Laws. Section 21 requires a certified mine examiner at every coal mine, and makes it his duty to examine the underground workings of the mine within eight hours preceding every day upon which the mine is to be operated; to carry a rod or bar for sounding the roof; to inspect all places where men are required to pass or work, and to observe whether there are any recent falls or dangerous conditions in rooms or roadways; to inscribe in some suitable place on the walls of each room, not on the face of the coal, with chalk, the month and the day of the month of his visit, etc. When working places are discovered in which there are recent falls or dangerous conditions, he must place a conspicuous mark or sign there as notice to all men to keep out. On completing his examination, he is required to make a daily record of the same in a book kept for that purpose, for the information of the company, the inspector and all other persons interested; and this record must be made each morning before miners are permitted to enter the mine. The examiner is further required to take into his possession the entrance checks of all men whose working places have been shown by his examination and record to be dangerous, and to give such entrance checks to the mine manager (boss) before the men are permitted to enter the mine in the morning. Section 20 requires the mine manager to examine the examiner's report every morning and, if working places are reported to be dangerous, he must withhold the checks of men working in such places until he has advised them of the danger existing and instructed them not to work in such places until the reported danger has been removed, except for the purpose of removing the same. When a miner is permitted to enter a place of work, he is entitled to assume that the manager and the examiner have performed the above stated statutory duties.

2. Although the Illinois Mine Law seems to contain no express requirement that a boss be put in charge of night shifts, it contemplates that there shall be some one in charge, as is shown by the following summary of provisions contained in Section 20: Where there is a night shift mining coal, the mine manager is required to see that an examination of the working places is made by the "person in charge of such night shift, or some competent person authorized by him," before the men enter such places of work. The mine manager is, also, required to see that the top man and bottom man are on duty when miners are being hoisted or lowered. In mines in which the works are so extensive that all the duties devolving upon the mine manager cannot be discharged by one man, competent assistants must be appointed.

*Attorney-at-law, St. Paul, Minn.

Advantages of the Modern Steam Shovel in Mining Shallow Seams

Since the advent of the steam shovel into the coal-mining field, the old method of strip-pit mining has almost entirely disappeared, and where one is found it is usually on a small scale. As first manufactured, the steam shovel did not seem to adapt itself successfully to coal operations; however, a rotary-type shovel has since been designed, which does the work so well that new shovel installations are constantly being added to operations in the various fields.

Some idea of the amount of money invested in this type of steam shovel can be gained by reference to the Ellsworth-Klaner Construction Co., of Pittsburg, Kan. This company has in operation two of the model 270 Marion shovels, of revolving type. These shovels each weigh about 250 tons, and, ready for operation, cost approximately $50,000. They represent the largest type of revolving shovel built, equaling in size those used on the Panama Canal works. They are equipped with a 5-cu.yd. dipper, and a 90-ft. beam.

The two owned by the Ellsworth-Klaner Co. have twin boilers and operating together, have moved as

IN THIS OLD PIT, 14 FT. OF DIRT HAS TO BE REMOVED TO REACH 40 IN. OF COAL. NOTE LARGE NUMBER OF MEN AND HORSES NEEDED FOR THIS METHOD

much as 6700 cu.yd. in one working day, lifting and depositing the load on top of the dump. By comparing this record with that made on the Panama work, where one shovel moved 4823 cu.yd. in one day, dumping it onto flat cars instead of hoisting it onto a high dump, the wonderful labor- and time-saving facilities of this method of top-vein mining can be readily appreciated.

The accompanying illustrations, and those on the front cover, serve to emphasize the value of the steam shovel in coal-mine operations.

The photograph of the old method of strip-pit mining was taken near Columbus, Kan., and is admirably calculated to indicate to the observer the great waste of labor, effort and time formerly required in working the top beds, where the crust was too thin to permit of underground development. In this particular operation it was necessary to remove 14 ft. of dirt in order to reach and expose from 3 to 3½ ft. of coal.

The labor was also most arduous, requiring the maintenance of a large force of men and many teams. The great expense and small output resulting from this method have tended to discourage extensive operations, and the advent of the steam shovel has therefore found an immense field in readiness for it.

THIS LARGE TYPE REVOLVING SHOVEL COSTS ABOUT $50,000 AND HAS A 5-CU.YD. DIPPER

Editorials

Pumping in Coal Mining

The April 4 issue of COAL AGE will be devoted altogether to the subject of pumps and pumping in coal-mining work. We are anxious to make this particular number of our paper the most interesting and complete issue of the kind ever printed. With this idea in mind, we invite all our readers to send us notes and articles descriptive of ideas and installations relative to the subject of pumping. All matter should be in our hands not later than Mar. 27. Wherever possible, photographs and drawings should accompany the text.

Systematic Timbering to Prevent Accidents

Everyone familiar with coal mining knows that roof falls kill more men than any other cause. Here and there occasionally in the United States we witness a spasmodic effort to enforce some definite scheme for safeguarding the men from falls of rock. Practically nowhere has an entirely satisfactory method of handling the timbering problem been evolved. British Columbia, alarmed by its increase in coal-mine fatalities, now comes to the front with a set of rules which, if enforced, are likely to better conditions in that field.

Attention is called to these rules and regulations, which are published elsewhere in this issue. This is a move in the right direction and is worthy of the notice of American operators, mine inspectors and miners.

Standardization

The standardization of methods and details of equipment in coal mining, as in all other industries, is one of the first elements of success. That it is unnecessary to draw the attention of the management of large operations to this need is evident from the great advance that has been made in that direction, by the leading coal companies.

While the average mine operator readily recognizes the need of standardization in the details of his own equipment and the methods of operation; and the manufacturer, likewise, recognizes the same need in the shop and factory, there is a growing necessity for the more universal application of this principle in the coal industry. Standardization in the details of manufacture of American watches, automobiles, engines, power generators and all classes of machinery and equipment, is recognized as one of the chief factors in the success and growth of these industries. The application of the principle by each operator and manufacturer, however, has been, to a large extent self-centered.

There is, at the present time, a growing necessity for the standardization of mining methods and equipment that will be general. While it is commonly recognized by all familiar with coal-mining conditions that such a general standardization of much of the equipment must be made with due regard to the varying conditions in mines, it is clear to anyone giving the matter careful thought that a great advance can be made in this direction. We naturally look to the Federal Bureau of Mines as the recognized agency through which such general standardization can be best effected. The bureau has already done much to secure the enactment of more universal state mining laws and the establishment of a more universal signal system in mines. There is great need for a more universal system of examination and certification of mine officials.

Few operators recognize the advantage that would accrue and the reduction in first cost that would result from the adoption of a more universal standard mine-track gage. The manufacturers of mine equipment are, today, required to bid on the rolling stock, adapted to any and all gages, varying from 18 in. to the standard railroad gage, 4 ft. 8½ in. The question of a more standard or universal mine-track gage has recently been raised, in manufacturing circles, and attention has been drawn to the fact that, while the need of certain variations in track gage is an absolute necessity under the varying mining conditions, a considerable reduction in the cost of furnishing this equipment would be effected by the adoption of a classified list of standard mine gages, say 24, 36, 42 in. and the standard railroad gage, 4.7 ft. The question is asked: Why order a 34-in. gage when a 36-in. gage would answer every purpose; and, yet, such various orders are given and bids required.

COAL AGE earnestly invites a discussion in its columns by manufacturers of mining equipment and practical mining men, regarding the advantages and disadvantages of the general adoption of such a classified list of mine-track gages. There are arguments on both sides of the question.

Cost of Living and Miners' Wages

It is interesting to compare the cost of living with miners' wages. To this end we take the figures compiled by J. K. Johnston from 1897 to 1912 and the index figures of the Department of Labor for all commodities which is a percentage comparison with the average cost of those same articles from 1890 to 1899. It will be seen that the percentage of advance in the cost of living is 48.94 per cent. This compares very closely with the increase in the selling price of coal in Allegheny, Washington and Westmoreland Counties of Pennsylvania. That increase, as figured by Mr. Johnston, was 53.62 per cent.

But the increase in miners' wages is very much larger than the enhanced cost of living and, of course, that is as it should be, because production constantly involves less labor and consequently the workingman should year by year be enabled to buy more articles than ever before. We seriously doubt, however, if other workingmen have done

nearly as well. In fact, this truth is indicated by the smaller increases secured by the per-diem men. The market for their labor is probably influenced unconsciously more by outside conditions than is the demand for the labor of miners.

COMPARISON OF WAGES AND COST OF LIVING, PITTSBURGH DISTRICT

Year	Wages per Ton Lump Coal	Wages per Ton Run-of-Mine	Wages per Day Max.	Wages per Day Min.	Index of Living Cost
1897	$0.55	$0.3558	$1.78½	$1.52½	89.7
1898	0.66	0.4272	1.90	1.75	93.4
1899	0.66	0.4272	1.90	1.75	101.7
1900	0.80	0.5171	2.28	2.10	110.5
1901	0.80	0.5171	2.28	2.10	108.5
1902†	0.80	0.5171	2.28	2.10	112.9
1903	0.90	0.5817	2.56	2.36	113.6
1904	0.85	0.5494	2.42	2.23	113.0
1905	0.85	0.549†	2.42	2.23	115.9
1906	0.90	0.5817	2.56	2.36	122.5

Per cent. advance	81.89	81.69	65.25	71.80	48.94

† Year of anthracite strike.

Figuring on the rate for lump coal, we see that the miner now gets $1 where he formerly got 55c. With it he can buy only what he could have purchased for 67.14c. in 1897. So the increase in the purchasing power of his wages has been 22.07 per cent., or about 1.38 per cent. per annum.

So much for figures; but it must be remembered that the Department of Labor bases its estimates on wholesale prices and the miner buys from the retailer.

In 1897 the company stores of the State of Pennsylvania were largely relied on to make up all the losses in the producing end of the industry and to furnish the profits. As one operator stated: "In the nineties, storekeeping was highway robbery."

Today we are disposed to think that the charge against the company store is that it does business on so large a scale that its low prices injure the business of the village stores at which farmers trade. Prices are now in nearly all cases reasonable and coercion to trade at the company store is certainly extremely rare and always closely veiled. In fact the evil practices of past days are perhaps entirely eradicated.

One Advantage of the B. T. U. Method

Disregarding the various merits and demerits of the B.t.u. method in general, it is probable that all will agree as to the desirability of the system under certain conditions. One such instance has recently been called to our attention.

An official of a large manufacturing concern was induced by a fuel-testing company to have a report and analysis made on a certain large consignment of coal. It was understood that the fuel was a high-grade "Fairmont," W. Va., product. When the analyses were completed, it was found the ingredients were such as to preclude any possibility of the coal having originated in the Fairmont district. It was also proved that it was impossible to ship Fairmont coal to the point in question (because of excessive freight rates) at the price under consideration.

Further investigations on the part of the official disclosed the fact that the coal was not a Fairmont product, a low-grade Pennsylvania fuel having been substituted. In tracing the matter through, it was ultimately discovered that this was but one of several schemes by which an unscrupulous purchasing agent had been defrauding his company for a number of years.

The National Mine Accident

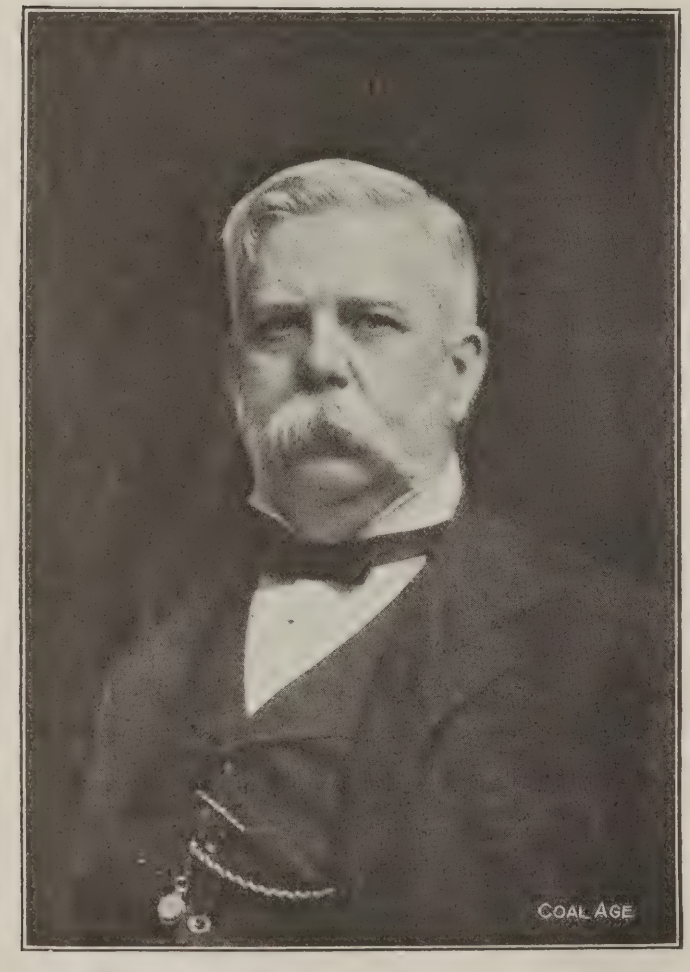
The statement made in our editorial, Mine Visitation, COAL AGE, Mar. 7, p. 415, in reference to the fatal accident that unfortunately occurred in the National mine of the Lackawanna Co., at Scranton, Penn., Monday night, Feb. 23, was based on the account given of this accident in the Scranton *Daily News*, Feb. 25.

We are advised by Supt. C. E. Tobey, of the Delaware, Lackawanna & Western R.R., Coal Mining Department, that the statement was incorrect in saying that the parties were lowered on the cage, and further, that they returned to the foot of an incline plane and watched the loaded cars going up and the empties coming down, there being no incline plane in that section of the mine. Mr. Tobey states that the parties walked quietly and secretly into the mine after dark, of their own accord, through one of the manway openings.

The editorial was written for the purpose of emphasizing the danger of strangers and persons unfamiliar with mining, visiting mines unaccompanied. All mine openings of any nature should be so protected and guarded that it would be practically impossible for any person to enter the mine surreptitiously. As stated in the editorial mentioned, it is common practice in the anthracite district to permit no unauthorized person to enter a mine without having a duly certified pass. The danger is not confined solely to the intruder, as an open light carried by such a one may ignite a body of gas with disastrous results; or, the ventilation may be deranged by the setting open of a door or the displacement of a brattice by a careless or ignorant person; or the signal system may be tampered with and put out of commission or made to give false signals, with fatal results. Every mine should be safeguarded at every point, in the surest manner possible.

The Panama Canal and Coal Mining

British mine owners for several years have had one eye on the Panama Canal, and the other on some special pieces of American coal acreage. Representatives of two important English syndicates have spent much time in this country recently looking the ground over. Because of its superior grade of coal and nearness to tidewater, the New River field in West Virginia has attracted their closest attention. Operators in this district have been quick to grasp the situation, and the price of New River coal land has been boosted materially.



After reading President Wilson's recent message to Congress on "Canal Tolls," one group of English capitalists recalled their representative, the explanation being that American coal lands were not so attractive, if the British ships can use the canal on equal terms with American shippers. One of these English syndicates has something like $25,000,000 to spend. This shows only one effect on American industry that will result through approval by Congress of President Wilson's canal policy.

George Westinghouse

George Westinghouse, famous as an inventor, an engineer and head of the Westinghouse interests, is dead; the end having occurred at his New York residence on Mar. 12. In him the United States has lost one of its most conspicuous and deserving citizens—one whose name was known and honored throughout the world.

George Westinghouse was born in Schoharie County, N. Y., on Oct. 6, 1846, to George and Emeline Vedder Westinghouse. His father was an inventor, and the seed of genius which was his flowered to splendid proportions in the son.

Prior to his 15th year, Westinghouse perfected his first invention, a rotary engine; and less than two years later successfully passed examination qualifying him as an assistant engineer in the United States Navy. It was in this capacity that he served throughout the greater part of the Civil War, resigning at its close to continue his college studies. He entered Union College, where he completed his sophomore year, withdrawing at that time to enter a more active field of endeavor.

RECENT PHOTO OF MR. WESTINGHOUSE

Shortly thereafter, while en route for Troy, N. Y., a delay occurring through the collison of two freight trains, suggested to him the need of an automatic brake. He began work at once on this idea and developed an automatic brake attached to the couplers. This was tried but proved unsuccessful, as did also a similar invention operated by steam. His first thought of using compressed air as a medium was the result of reading an account of its use in digging the Mont Cenis tunnel, 3000 ft. under ground. He readjusted his plans at once, and soon perfected drawings of the air brake, brake cylinder and valves. Later, a practical trial was obtained, and the invention demonstrated a success.

The first patent was issued on Apr. 5, 1869, and the Westinghouse Air Brake Co. launched in the following July.

In 1870, the manufacturing works were completed, and Mr. Westinghouse went abroad to introduce the air brake into England.

Many changes and improvements were being made in the brake all the while, and business flourished. At an early date, the automatic feature of the brake was invented, thereby removing the danger of the parting of trains on steep grades; and, in 1886, the "quick-action" brake was perfected, the improvement consisting in what is known as the "triple valve," by which it is practicable to apply in two seconds all brakes on a 50-car freight train.

About 1880, Mr. Westinghouse became interested in the operation of railway signals and switches by compressed air, and soon thereafter developed and patented the "Pneumatic Interlocking Switch and Signal Apparatus," whereby all signals and switches are operated from a given point.

In 1886, the Westinghouse Electric Co. was formed for the manufacture of lamps and electric-lighting apparatus. The business rapidly developed, and in 1889 and 1890, this company absorbed the United States Electric Co. and the Consolidated Electric Light Co. In 1891 all of these properties were reorganized into the Westinghouse Electric & Manufacturing Co., which now owns extensive works in East Pittsburgh, employing over 22,000 people.

The question of the steam turbine and its application was investigated by Mr. Westinghouse; and in collaboration with the late Admiral George W. Melville, U. S. N., and John H. MacAlpine, he brought out one of the most ingenious devices of modern engineering—the mechanical reduction gear for reducing the inherently high speed of a turbine to the slow speed of a ship's propeller or direct-current dynamo.

Mr. Westinghouse rendered an invaluable service to the electrical development of the world when, in spite of opposition and ridicule, he remained steadfast in his efforts to perfect the alternating-current system and in his belief that this class of high-tension transmission would make distant electrical distribution possible. This system was perfected by his engineers, one of whom, Nikola Tesla, in 1887, invented the alternating-current induction motor. The world today, lighted by distant waterfalls and central stations, recognizes its debt to the foresight and perseverance of George Westinghouse.

Originating with one of the most important inventions connected with railways, the growth of the various Westinghouse industries has been largely identified with railway progress, and it is interesting to note that this progress has represented increased security of life, increased carrying capacity, and reduced cost of operation.

Mr. Westinghouse was connected with a large number of industries at home and abroad, many of which bore his name. He was president and director of Westinghouse Air Brake Co., Westinghouse Machine Co., Nernst Lamp Co., Union Switch & Signal Co., Société Anonyme Westinghouse, Paris, Cooper Hewitt Electric Co., Pittsburgh Meter Co., Société Italiane Westinghouse, Italy, East Pittsburgh Improvement Co., Westinghouse Brake Co., Ltd., London, Westinghouse Cooper Hewitt Co., London, Westinghouse Friction Draft Gear Co., Westinghouse Metal Filament Lamp Co., Ltd., London. He was also chairman of the board of directors of Westinghouse Electric Co., Ltd., London, and director of Westinghouse Electric & Manufacturing Co., Traction & Power Securities Co., Westinghouse Metallfaden Gluhlampenfabrik, Vienna.

The Westinghouse companies employ 50,000 men on whom 150,000 persons are dependent. The total capitalization of all the companies is $200,000,000.

Owing to his many achievements in mechanics, electricity, steam and gas he had many honorable distinctions conferred upon him. His alma mater, Union College, conferred upon him the degree of Ph.D. He was decorated with the order of the Legion of Honor; with the order of the Royal Crown of Italy, and with the order of Leopold of Belgium. He was the second recipient of the John Fritz medal. He received the degree of doctor of engineering from the Koenigliche Technische Hochschule, of Berlin. He was an honorary member of the American Society of Mechanical Engineers, of which body he was also president of 1910. He was one of the two honorary members of the American Society for the Advancement of Science. He was an honorary member of the National Electric Light Association of America. He was awarded the Scott premium and medal by the Franklin Institute of the state of Pennsylvania. He received the Edison gold medal for meritorious achievements in the alternating-current system of electrical distribution. He received the Grashof gold medal from the Society of German Engineers in Germany, which acknowledged him the greatest American engineer.

Mr. Westinghouse was married Aug. 8, 1867, at Brooklyn, N. Y., to Marguerite Franklin Walker. They had one son, George, who is a graduate of Yale, and who was recently married to the Hon. Evelyn Violet Brocklebank. His wife and son survive him.

Discussion By Readers

Mine Cars

Some time ago, attention was called, in a foreword, COAL AGE, Vol. 4, p. 639, to the size and kind of mine cars best adapted for use in coal mines. This has always been a matter of interest to me, and I beg to submit a few practical considerations that must be taken into account before deciding on the size and style of mine car that can be used to advantage in a given mine.

In coal mines, where it is necessary to take the cars to the working face to be loaded, the height of the seam practically limits the height of the car.

A bad roof or a heaving bottom will often require the driving of narrow entries, which, again, limits the width of the car that can be used under such conditions.

The length of mine car is generally limited by the width of the hoisting shaft. There should always be a safe allowance made for clearance in the shaft, varying from, say 6 to 12 in. at each end of the car. Unless otherwise specified, an actual clearance of 6 in. should be allowed and a further deduction of 6 in. should be made for the bumper and end board of the car, at each end; making the inside length of the car 2 ft. shorter than the clear width of the shaft.

The required capacity of mine cars is largely determined by the conditions in respect to the desired output of the mine, length of haul underground, grades of haulage roads and the kind of haulage employed; the last named item limiting the number of cars that can be hauled in a single trip. In deciding upon the capacity of cars, it is important to have due regard to the size and weight of car that can be handled under the conditions existing in the mine. This is determined practically by the condition and inclination of the tracks, the kind of tracking used, and the size of car wheels and condition of the rolling stock in general.

While men can push cars weighing 3000 lb. and carrying a load of 2½ tons, such cars are difficult to start and stop. In order to have the car always under control, it may be necessary to equip every car with a brake or to employ sprags, which are short, bobbin-shaped oak sticks that can be thrust into the wheels between the spokes, to prevent the wheel from turning. To insure safety and ease of handling, cars should not have a capacity exceeding, say 2 or 2½ tons, depending on the condition, inclination and kind of track.

Mine-car wheels are a most important factor in underground haulage. The size or diameter of the wheel and the manner of mounting, facility of lubricating and resistance to wear, both in the journal boxes and on the tread of the wheel, all exert an important influence on the ease with which the car is moved along the track and made to perform its office with the least interruption and delay. Mine cars having wheels 14 to 16 in. in diameter are much more easily moved than cars with wheels 8 or 10 in. in diameter.

The track gage is an important factor, which must be decided largely in accordance with the physical conditions in the mines. Narrow gages permit an easier movement of the cars than is the case on broad-gage roads, under similar conditions. Narrow gages also admit of the use of sharper curves than is possible with broader gages. In common mining practice, in this region, the mine-track gage varies from 28 to 42 in., depending for the most part on the size of the car employed.

The wheel base, by which is meant the distance between the axles or the wheel centers, is also an important consideration. This rarely exceeds 42 in., and is often only 30 in. Cars with a short wheel base can be used on sharper curves, and when derailed they are more readily replaced on the track. Improved wheels with roller bearings have been used for mine cars with great success.

Bituminous-mine cars are built in a great variety of shapes, styles and sizes. These seldom have a capacity of over 100 cu.ft., or, say 2½ tons, the average capacity being from 1.5 to 2 tons. The cars are usually built with outside wheels, the sides being flared above the wheels to provide an increased capacity. The cars are built for varying gages, and both loose and fixed wheels are used. Though wooden cars are generally employed, there are many steel cars in use. The latter have numerous advantages and some disadvantages. Though the first cost is higher than that of wooden cars, steel cars greatly outlast the latter.

GEORGE STOCKDALE.

Percy, Penn.

The Mine Worker

In his article, "One Reason Why Workmen Are Dissatisfied," COAL AGE, Jan. 3, p. 3, I doubt not that Ernest L. Bailey is honest in the opinions he there sets forth. My observations, however, have not led me to the conclusion that the laboring man "contemplates the division of the world's goods as a panacea for unhappiness and an end of toil"; or, that he regards his work "in the light of a makeshift against that time when the apportioning committee will hand him out his pro-rata share of the world's wealth."

I am not now speaking of labor leaders or agitators of a certain class, nor, yet, of the idler who does as little work as possible for as much pay as possible. I refer to the average, conscientious laborer or miner, who is anxious to give a day's work for a day's pay. I have faith enough in humanity to believe that the average laborer or miner is a conscientious worker.

In his social relations, the true mine worker is right in his belief that he has certain inalienable rights and can justly claim a few things above a place to sleep, food to eat and clothes to wear. His claim that he has a right to own his own home should be warmly supported by his employer. His ambition to furnish his home with comfort, not to say luxuries, should be encouraged. His tastes are simple, his needs few, and he has little desire or place for luxuries.

The mine worker has a right to a common-school education for himself and his family. The conditions of labor should be such that the conscientious worker will be able to keep his children in school during their younger years. Surrounding conditions should never be such as to permanently separate him from his family and forbid him the comfort and pleasure of home life.

Every worker has a right to certain diversions that serve to make life enjoyable as well as profitable. His work is made more efficient when he is able to devote a small portion of each day to social pleasure, exercise and study or reading. The hours so employed by the worker are as important and as remunerative to the employer as to the employed, because the worker is made stronger and more efficient and works with greater zest. It should be possible for the man who works by the day or week to be able to enjoy a brief respite or vacation that he can spend as he wishes on a hunting or fishing trip, or visiting old friends.

What it takes to secure these things for the worker constitutes, in my opinion, a "living wage," and is the honest worker's right. It is true, he may make his own choice of the manner in which he spends his time and money. He may choose between a bank account and a piano; or make a considerable sacrifice to secure an education for himself or some member of his family; but this sacrifice is at his own option and differs from that often forced upon him by untoward conditions under which he must work.

The average true worker does not want his employer's wealth. He knows he is a producer. The suggestion is unworthy of sober thought, that the true workman envies the possessions of another and desires that the owner of an industry should be dispossessed and his wealth distributed. The honest toiler is naturally independent and prides himself on his ability to do for himself and his own. He despises the dishonest workman who depends on the efficiency of another to cover his own lack. He has no use for the parasite in society or industry.

GEORGE N. LANTZ.

New Straitsville, Ohio.

Safety or Refuge Chambers in Mines

While there has been an occasional mention of the adoption of safety chambers in mines, as providing a means of escape from the effects of the afterdamp of mine explosions, one can but feel that insufficient attention is being given to this matter, in a practical way.

At the present time, we hear much of the "Safety First" idea. Would it not be well, now, to turn our attention, in some measure, to what might be called the "Safety After" idea? Much study has been given to the cause and prevention of mine explosions. The experiments, at Bruceton, have proven beyond a doubt that coal dust is explosive and that its presence in the mine workings is a menace to safety. There have been many suggestions to render the mine immune from explosions; but, after all has been done, explosions still continue.

It is true that much time and money are spent in the development of mine-rescue work, and the training of rescue corps, which we are forced to believe has been satisfactory only in a limited sense. In some cases, the heroic efforts of would-be rescuers, equipped with rescue apparatus, have resulted in sudden death to themselves. This is no reflection on those who have thus braved death to rescue others; but is, rather, a testimony of their courage and devotion to duty as they understand it. We must agree that, to attempt to save men suddenly enveloped in a death-dealing atmosphere, in darkness, among falling roof and timbers and surrounded by everything that conspires to kill, is a dangerous if not a well-nigh impossible task.

Is it not true that we have been studying this matter of rescue from its most dangerous side? The question may be asked: Do not these devoted rescuers brave a greater danger, in many cases, than that faced by those whom they would rescue? In every mine explosion, those who escape death are the ones who are fortunate enough not to have been caught in the path of the explosive blast, and who continue to breath mine air as yet not contaminated with the poisonous gases of the explosion. They have felt the concussion of the explosion that took place in another portion of the mine and they know too well its meaning. They realize the danger that confronts them, and their minds run riot, as to what to do or where to go. No time is to be lost; overtaken by the deadly afterdamp, their fate is sealed. Under these conditions, with no alternative, they rush toward daylight and safety, forgetful of or willing to hazard, as their only means of escape, the deadly atmosphere of the main roads leading out of the mine.

No argument is required to show what a boon to these men, would have been one or more properly equipped safety chambers, located at convenient points in the mine, to which they could have retired, instead of being forced to accept the only alternative of escape by passing through airways laden with deadly gases. Had such refuge places been provided, the survivors of the disaster in the mine, instead of being powerless and defenseless, would have been provided with all that was needed to insure safety.

The plan of such refuge chambers is simple and can but appeal to all practical mining men. A borehole or two would place the chamber in communication with the surface and permit of the ample ventilation of the place by the introduction of fresh outside air, and provide also a way of supplying food and other necessities. The chamber should be well secured against roof falls or the invasion of the deadly afterdamp of the mine. There should also be provided suitable first-aid equipment and restoratives. Would not the Federal Bureau of Mines do well to elaborate this scheme?

CHARLTON DIXON.

Pittsburgh, Penn.

The Hookworm Danger in Mining

The interesting and well illustrated article on "Concrete Vaults in Colliery Villages," COAL AGE, Feb. 7, p. 256, by Pennsylvania Mining Engineer, describes a great advance. All owners of coal-mining villages should read the article. It is from defective closets and, more often, from no closets at all that the hookworm spreads rapidly.

This subject has received little attention, while typhoid fever, and "swatting the fly" have received their full share. The hookworm revels in coal dust, particularly if it is damp. To lessen one danger, we increase

that from another source. We sprinkle the mine to prevent dust explosion, and thereby invite the development of the hookworm. The native hookworm has long existed in the Southern states, but after making careful investigation among the miners, in a section of West Virginia, I find many indications of its presence there, also. What is true of West Virginia, in this respect, is probably true of other coal fields in the states. Dr. Anders, a good authority and the author of a very popular textbook on the "Practice of Medicine," without special reference to the prevalence of the worm among miners, states: "The importation of infected Italian, Hungarian and Polish laborers into this country, may be accountable for the propagation of the parasite in the United States.'" At certain mines in West Virginia these classes of labor abound.

This parasite, the hookworm, became such a menace to health and detriment to labor, that it has been fought abroad by governmental commission. It is said by an authority on the subject that its presence renders certain of the most fertile portions of the earth uninhabitable.

West Virginia is famous beyond all states for the number of fatalities in its coal mines; and, strange to say, many of these fatalities are indirectly due to this small worm. The female worm never exceeds 0.25 in. in length. I have practiced medicine in the coal fields of West Virginia for many years and can usually tell from the "facies" and general appearance of a miner when he is infected with hookworm. Often, as I look on the dead face of a miner who has been killed by a fall of slate, because he did not prop his roof in time, I can read there the ravages of the worm. It causes weakness and carelessness. Ths man is sick though he does not lose flesh. He harbors a creature that looks like a miniature canthook. It is located high up in the intestine, which on account of its conformity is too steep for any other creature to hold on. He retains his position there by holding on with two hooks; while he bites with four teeth. He cannot be dislodged by the usual old-fashioned methods as easily as with a new remedy. He probably does more harm by poisoning the blood than by extracting anything from it.

To better this condition among miners, it is more important to have sanitary closets *inside* than outside the mine, and to enforce the most rigid discipline that such closets be used. There would seem to be no danger from the urine. The positive diagnosis of the disease is made from a microscopic discovery of the eggs. The adult worm is seldom passed except as the result of medicinal measures.

Thurmond, W. Va.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

3. (a) Calculate the value of the pressure potential for the entire mine mentioned in the preceding question, the airways being 6x10 ft. in section and about 16,000 ft. long, including the return, assuming as before two equal splits; and (b) calculate from this pressure potential the power that will produce the desired circulation of air; namely 75,000 cu.ft. per min. and the resulting water gage.

Solution—(a) The total rubbing surface is $s = 2\ (6 + 10)\ 16{,}000 = 512{,}000$ sq.ft. For two equal splits, the area of passage in this mine is $a = 2\ (6 \times 10) = 120$ sq.ft. The mine pressure potential is then

$$X_p = a\sqrt{\frac{a}{k\,s}} = 120\sqrt{\frac{120}{0.00000002 \times 512{,}000}} = \textit{say}\ 13{,}000$$

(b) The power on the air, calculated from the pressure potential, is then,

$$u = \frac{q^3}{X^2_p} = \frac{75{,}000^3}{13{,}000^2} = \textit{say}\ 2{,}500{,}000\ \textit{ft.-lb. per min.}$$

The water gage, calculated in the same manner, is

$$w.g. = \frac{1}{5.2}\left(\frac{q}{X_p}\right)^2 = \frac{1}{5.2}\left(\frac{75{,}000}{13{,}000}\right)^2 = 6.41\ \textit{in.}$$

4. What volume of air will 10 hp. circulate in an airway 6x8 ft., in section, and 2500 ft. long?

Solution—The sectional area of this airway is $a = 6 \times 8 = 48$ sq.ft.; the rubbing surface $2\ (6 + 8)\ 2500 = 70{,}000$ sq.ft. The power potential is therefore

$$X_u = \frac{a}{\sqrt[3]{k\,s}} = \frac{48}{\sqrt[3]{0.00000002 \times 70{,}000}} = 429.1,\ \textit{nearly}$$

For 10 hp. on the air, the quantity of air in circulation in this airway is

$$q = X_u \sqrt[3]{u} = 429.1\ \sqrt[3]{10 \times 33{,}000} = \textit{say}\ 30{,}000\ \textit{cu.ft. per min.}$$

5. (a) What quantity of air will be circulated, in the airway, in the last example, under a 3-in. water gage; and what power on the air will be necessary to develop this quantity and gage? (b) What was the original water gage when 10 hp. circulated 30,000 cu.ft. of air, in this mine?

Solution—(a) Since the square of the pressure potential is equal to the cube of the power potential

$$X_p = \sqrt{X^3_u} = \sqrt{429.1^3} = 8890,\ \textit{nearly}$$

Then, $q = X_p \sqrt{p} = 8890 \sqrt{5.2 \times 3} = \textit{say}\ 35{,}000\ \textit{cu.ft. per min.}$

The power required to produce a 3-in. water gage is

$$H = \frac{35{,}000 \times 3 \times 5.2}{33{,}000} = \textit{say}\ 17\ \textit{hp.}$$

(b) The previous water gage due to the circulation of 30,000 cu.ft., in this mine, under 10 hp. can be calculated in several ways; but most simply, thus,

$$w.g. = \frac{10 \times 33{,}000}{5.2 \times 30{,}000} = 2.1\ \textit{in.}$$

The Coal Age Pocket Book

The calculation may also be made from the potential; thus,

$$w.g. = \frac{q^2}{5.2 X^3_u} = \frac{30{,}000^2}{5.2 \times 429.1^3} = 2.1\ \textit{in.}$$

Area of Passage—It is important to notice that the potential value for any mine is determined by its area of passage with respect to the resisting power of its rubbing surface. For a single air current the area of passage is the sectional area (a) of the airway. For 2, 3, etc., equal splits the area of passage is 2a, 3a, etc.; for n equal splits the area of passage, for the mine, is na.

The unit of resistance being k, the resisting power of the entire airway or mine is indicated by ks; and the potential values of the mine with respect to power and pressure of circulation, respectively, are thus expressed

Mine power potential, $X_u = \sqrt[3]{\frac{(n\,a)^3}{k\,s}} = \sqrt[3]{n^3}\sqrt[3]{\frac{a}{k\,s}}$

Mine pressure potential, $X_p = \sqrt{\frac{(n\,a)^3}{k\,s}} = n\,a\sqrt{\frac{n\,a}{k\,s}}$

It should be observed that the mine power potential varies as the number of equal splits or currents, which is not true of the pressure potential of a mine. This fact has an important application, since, for the same mine, the rubbing surface being constant, the number of splits (n) is equal to the power-potential ratio. An example will serve to make this clear.

Example—Suppose it is desired to ascertain quickly how many equal splits would pass the same quantity of air (75,000 cu.ft. per min.), in Example 3, on the preceding page, under a 2-in. water gage, where two splits of air gave a water gage of 6.41 in.

Solution—The area of passage for two splits in this mine is $na = 2 \times 60 = 120$; and the rubbing surface being $s = 512{,}000$ sq.ft., the mine power potential is

$$X_u = \frac{n\,a}{\sqrt[3]{k\,s}} = \frac{120}{\sqrt[3]{0.00000002 \times 512{,}000}} = 552.6\quad (2\ \textit{splits})$$

The power potential for a circulation of 75,000 cu.ft. of air under a 2-in. water gage is

$$X_u = \sqrt[3]{\frac{q^2}{5.2\ w.g.}} = \sqrt[3]{\frac{75{,}000^2}{5.2 \times 2}} = 814.8\quad (n\ \textit{splits})$$

Since the number of equal splits varies as the power potential, the split ratio is equal to the power-potential ratio, which is n : 2. Hence,

$$\frac{n}{2} = \frac{814.8}{552.6} = 1.47$$

$$n = 2 \times 1.47 = \textit{say}\ 3\ \textit{splits}$$

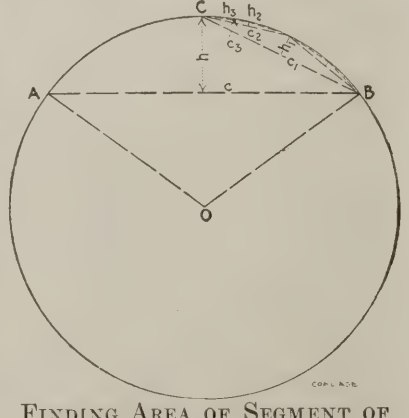
The reference, thus far, has been to the equal division of the air current, and the rules and formulas given above apply strictly, only to mines in which the air current is divided at or near the main entrance and passes through the mine in two or more separate and equal splits.

Inquiries of General Interest

Mensuration--The Circle

Can you give a formula, without the use of trigonometry, for finding the sectional area of a circular segment or the area of that portion of cross-section lying beneath the flat arch of a tunnel and above the springing line? The clear span of the arch is 12 ft., and the rise at the center, 3 ft. The arch is an arc of a circle.

California, Penn. READER.



The simplest method of calculating the segment of a circle is to divide the half-chord of the arc by its radius, which gives the natural sine of the angle corresponding to half the arc. If the chord (c) of the arc and the rise (h) *only* are given, the radius (r) can be found by dividing the sum of the squares of the half-chord and the rise, by twice the rise of the arc or height of the segment, as expressed by the formula

$$r = \frac{(c/2)^2 + h^2}{2h}$$

Having found the radius of the circle, calculate the entire area (πr^2) of the circle, and multiply this total area by the ratio of the angle subtending the half-arc to 180 deg., which will give the area of the sector included between the arc and the two radii drawn to its extremities. To obtain the area of the segment subtending the arc, subtract from the area of the sector just found, the area of the triangle formed by the chord and the two radii mentioned. The area of this triangle is equal to the half-chord ($c/2$) multiplied by the radius of the circle less the rise of the arc ($r - h$). This is the usual and simplest method of calculating the area of a segment of a circle.

In order to avoid the use of trigonometry, in this calculation, it is necessary to adopt the same method of approximation that is used in finding the value of π for calculating the area of a circle. This method is as follows:

Referring to the accompanying figure, the first step is to calculate the area of the sector $OACB$; and from this subtract the area of the triangle OAB, as before. The area of the sector is equal to the length of the arc ACB multiplied by one-half of the radius OB. The length of the arc ACB not being given, may be calculated, approximately, as just stated, by finding the length of one of a number of small equal subchords, whose sum will approach very closely to the actual length of the arc.

FINDING AREA OF SEGMENT OF CIRCLE

Calling the original chord and rise of the arc c and h, respectively, and designating each subchord and corresponding rise, for each successive equal division of the arc, by c_1h_1; c_2h_2; c_3h_3, etc., it is evident that an expression of the total length of the arc ACB can be found by taking the sum of, say n equal subchords. Each successive subchord being calculated from the preceding one, the nth subchord will finally be given in terms of the original height or rise and the radius of the arc.

Without showing the development of this method, it will be sufficient to give the two basal formulas employed for finding the length of a subchord from the chord and rise of twice the arc subtended by that subchord. Since any chord of a circle is a mean proportional between the diameter and the rise of twice the arc subtended by that chord, the length of a subchord c_1 (see Fig.) is given by the formula

$$c_1 = \sqrt{2rh} \qquad (1)$$

This formula makes it possible to calculate the length of a chord of half an arc when the rise and the radius of the arc are known.

Again, since the half-chord ($c/2$) of an arc is a mean proportional between the rise (h) of the arc and the diameter of the circle less the rise of the arc ($2r - h$), the rise of any arc is equal to the radius minus the square root of the sum of the squares of the radius and half the chord subtending the arc, as expressed by the following formula (see Fig.):

$$h = r - \sqrt{r^2 - (c/2)^2} \qquad (2)$$

Now, applying formula (2) to find the rise (h_1) of the arc CB, corresponding to the first subchord (c_1), by substituting the value of this subchord, as given by the formula 1, in formula 2 and simplifying, the following simple formula is obtained, which gives the rise of the first half-arc, in terms of the rise and radius of the original arc; thus,

$$h_1 = r\,(1 - \sqrt{1 - h/2r}) \qquad (3)$$

This process can be extended and applied for finding the rise corresponding to an indefinite number of equal subdivisions of arc. If there are n subdivisions, the length of subchord (cn), which is approximately the length of the corresponding arc, is found by substituting the calculated rise (hn) in the formula

$$cn = 2\sqrt{hn\,(2r - hn)} \qquad (4)$$

Finally, multiply the length of this subdivision of arc by the number of subdivisions (n) to obtain the length of the original arc ACB; and, again, multiply the calculated length of arc ACB by one-half the radius r, to obtain the area of the sector $OACB$; and from this area of the sector, subtract the area of the triangle OAB to obtain the area of the segment ACB. These areas are given by the following formulas:

$$\text{area of sector} = nr\sqrt{hn\,(2r - hn)} \qquad (5)$$

$$\text{area of segment} = r\,[n\sqrt{hn\,(2r - hn)} - c/2] \qquad (6)$$

Examination Questions

Miscellaneous Questions

(*Answered by Request*)

Ques.—If, on entering the mine as a fireboss, you found one of the splits completely shut off from the intake air, by a heavy fall of roof, what would be your duty in this case?

Ans.—The bituminous-mine law requires the fireboss to "place a danger signal across the entrance to every working place and every other place where explosive gas is discovered or where immediate danger is found to exist from any other cause." (Art. 5, Sec. 1.) He is also required (Sec. 2), immediately after completing his examination of the mine, to make and sign a pen-and-ink record of the same, in a book kept at the office for that purpose. The law states: "This record shall show the time taken in making the examination, and, also, clearly state the nature and location of any danger that may have been discovered in any room or entry, or other place in the mine." The fireboss must also "immediately report the location thereof to the mine foreman," whose duty it should be to see that the danger is removed as quickly as possible; and, till this is done, and the section examined and reported safe, no one must be permitted to enter that section of the mine.

Ques.—In making the examination of a mine for firedamp, could it happen that a fire would be found burning in one of the rooms turned off one of the headings; and what would be your duty in such a case?

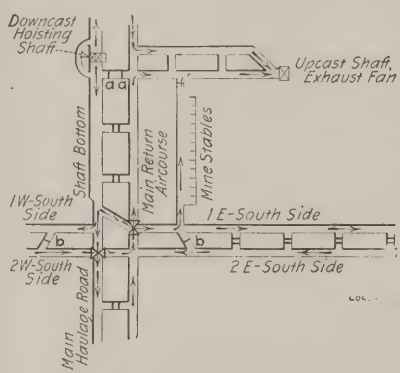
Ans.—It frequently happens that the fireboss, in making his morning examination, finds that a fire has started at or near the working face. In most cases, this is due to the ignition of a gas feeder, by the flame of a shot; and, no one being present to extinguish the feeder, the coal became ignited and the fire gained considerable headway before it was discovered by the fireboss on his morning round.

The fireboss should at once give the alarm, so that steps can be taken to extinguish the fire, assuming that he is not able to do this himself. In some cases it may be possible to short-circuit the air so as to prevent the smoke and gases from the fire penetrating further into the mine workings. This should be done at once if it will not render other portions of the mine dangerous. It may, also, be practicable and necessary to reduce the circulation of air passing over the fire. In any case, no time must be lost in giving the alarm and securing efficient help.

Ques.—What should be the height of the motive column formed when the depths of the downcast and upcast shafts are each 300 ft., the temperature of the downcast shaft being 32 deg. F., and that of the upcast, 48 deg. F.?

Ans.—The height of the motive or air column, in terms of the *downcast* air, is calculated as follows:

$$hd = \frac{(48 - 32)\ 300}{460 + 48} = \frac{4800}{508} = 9.45\ ft.$$



In like manner, the height of motive column may be calculated in terms of the *upcast* air, as follows:

$$hu = \frac{(48 - 32)\ 300}{460 + 32} = \frac{4800}{492} = 9.76\ ft.$$

Ques.—How should a stable in a mine be constructed and ventilated.

Ans.—A mine stable should be constructed in as nearly a fireproof manner as possible. It should be sufficiently high to permit of good ventilation, without producing a high velocity of the air current. The roof must be well secured against falls. It should have a good cement floor, be well drained, and ample provision should be made for the storage of the daily feed and refuse.

As shown in the accompanying figure, a mine stable should be located in close proximity to the bottom of the shaft, for the more economical handling of supplies and refuse, and the rescue of the mules, in case of emergency. The stable should be so arranged with respect to the intake and return airways, that it can be ventilated by a small scale of air taken from the intake current, which is returned at once to the main return airway and conducted out of the mine without passing through any other section of the mine. As shown in the figure the circulation of air through the stables should be controlled by double doors at the return end.

SHOWING ARRANGEMENT OF MINE STABLE

Ques.—How is air put in motion for the ventilation of a mine?

Ans.—Air, like other fluids, moves from a point of higher pressure to a point of lower pressure. There is always required, therefore, a certain excess of pressure in the intake airway over that in the return. This excess of pressure is created by means of a blowing fan at the intake opening, or an exhaust fan or furnace at the return opening or upcast shaft. The difference of pressure between the intake and return airways is called the unit of ventilating pressure.

Ques.—How many systems of ventilation are there in mining?

Ans.—There are two general systems of ventilation, known as the "blowing system," in which the air is forced or blown through the mine, under a pressure greater than that of the atmosphere; and the "exhaust system" in which the action of the mine ventilator causes a vacuous condition in the return airway, and the atmospheric pressure at the intake opening forces air into and through the mine. The mine is then said to be ventilated under a pressure less than that of the atmosphere.

Coal and Coke News

Washington, D. C.

President Wilson has signed the Alaska railroad bill, which is designed to give him the power to construct a railroad in Alaska, located at his own discretion, in such a way as to furnish means for opening up the coal fields and other natural resources of the territory. The bill as already well known provides an appropriation of $35,000,000 to be obtained as needed through the issue of bonds, but $1,000,000 of which is made available in advance by means of direct appropriation from the Treasury. The understanding is that there will be no delay in starting the work and Secretary Lane, of the Interior Department, has already had a long conference with the President about the selection of the men who are to participate in the locating and constructing of the new line.

An interesting phase of this matter, however, is found in the fact that it is one element in a large program of Alaskan exploitation, which is primarily intended for the opening up of the coal fields and has in view the substitution of government enterprise for private control and operation of the mining possibilities of the territory. It is now intended to push as a completion of the scheme, the bill providing for the so called "Alaska Development Board," which is to consist of three persons appointed by the President to "have jurisdiction and control over the care, use and disposition of all reserved and unreserved public lands, including forests and waters and resources—mines, minerals and mining." While it may not be that there will be any effort at direct government operation of the mines of Alaska, even if the whole program that the Administration has in mind goes through, several such schemes are already on foot and may have more or less importance.

Representative Bryan has introduced a bill intended to provide for the immediate and rapid development of Alaskan resources at a greater speed than seems likely to be possible under the very broad general policy of development that has been mapped out by the Administration in connection with its Alaskan railroad plan. His scheme is to organize a service to be known as the "Alaska Mining Service," for the purpose of getting out coal. The "Alaska Mining Service" would be "charged with the duty of operating coal mines on lands reserved to the Government and the distributing stations and of selling coal," in a manner to be prescribed. The bill then goes on to indicate methods of leasing at the discretion of the President and to prescribe the methods of employing men in the event that the President deems it preferable to do the mining himself. In the event of leases, the land thus leased is not to exceed 3,200 acres, and no person interested in common carriers is to be allowed to own or have any interest as a stockholder or otherwise in any lease. The charge for the lease is to be at the following rate: "25c. per acre of the leased premises for the first year; 50c. for the second year; $1 for the third year," and thereafter the same charge per annum throughout the continuance of the lease. A certain percentage of the proceeds of the enterprise are to be set aside and kept for the purpose of improving, extending and developing the transportation and other facilities for coal mining in the territory of Alaska.

HARRISBURG, PENN.

It is reported here that American coal is blamed for the total failure of the new coke-oven plant at South Bethlehem. Practically every one of the 300 ovens will soon be useless.

In Germany the ovens would have worked to a nicety, but the American coal generated so much greater heat that the insides of the coke ovens have been unable to withstand it. The entire battery of 300 ovens erected at a cost of between $6,000,000 and $8,000,000 are an almost total loss and will be torn down.

The Didler-March Co., a German concern, was the constructing company, and the financial banker was the Deutsches Bank, of Germany. On the latter, it is said, will fall the heaviest loss.

It is also said that the brick used in the construction of the ovens, especially the inside, was of an inferior kind. When the Germans received the contract to erect the first coke ovens of their kind in America, they started a brick-making plant at Valentine, N. J. Unfortunately, this burned down some time ago and the Germans had to look elsewhere for constructing material.

They were practically swindled, it is alleged, for the quality of brick was decidedly inferior and melted under the intense heat.

Money ran like water in the building of the plant. Wages were high, and policemen who were employed to guard approaches to the plant, were paid 50 per cent. more than the policemen of Bethlehem. The Germans are acknowledged to have the best patents on the methods of coking in the world, and their efforts to guard against the stealing of these patents were costly. A force of high-priced detectives was employed for a time.

When the furnaces were first started it was calculated that 150 carloads of coal a day would be required. This, provided the ovens worked all right. But they didn't. Nevertheless the 150 cars of coal continued to arrive each day, and soon the yards were overflowing, and heavy demurrage charges resulted.

But things have not changed with the formal transfer this week of the plant to the operating company, the Lehigh Coke Co. Another start is to be made. The worthless plant is to be dismantled and new batteries of between 400 and 500 ovens are to be built, and will use about 5000 tons of coal a day.

The original contract called for the erection and operation of the plant by the Germans, C. M. Schwab to furnish all the coal and get all the coke and gas, the Germans to receive the byproducts from which they hoped to make millions of dollars a year.

* * *

One of the most striking articles that has come from the Anthracite Operators' Press Bureau, is the one issued about Mar. 12. It cites the reason of one of the best known mining officials in the anthracite region for granting the check-off to the United Mine Workers.

The article is as follows:

If over a half century "on the job" carries any weight of conviction, a letter recently received by Samuel D. Warriner, president of the Lehigh Coal & Navigation Co., presenting a miner's view of the United Mine Workers' recent request for the check-off in the anthracite region of Pennsylvania should be of interest.

"Having been during a period of over fifty years a member of several miners' organizations, including the U. M. W. of A.," he wrote, "I have always believed in the protection of labor to obtain fair and living compensation in so far as the same can be accomplished between employer and employee in the most peaceable manner."

In stating his views on the question of the check-off—the retaining of union dues and assessments from the employees' wages to turn over to the union—the veteran miner voiced his protest on the ground that it was "unconstitutional and against the liberty and free will of every fair and intelligent wage earner."

His views on the disposition of the assessments, fees and monthly dues after they are collected by the check-off, were even more drastic. He pointed out that they could be used to create additional officials and to increase the salaries of the existing officials. "The whole amount of funds collected," he said, "could be used to further their careers and maintain their official positions irrespective of any protest presented by any local of the union which learned of any imposition by the officials in the shape of discrimination, graft or speculating with the funds."

"Not only these things are true," he continued, "but I have found from experience that political capacities are more or less maintained from union funds to promote any alleged union officials and have read of many who were back-sliders to that which they represented before their promotion.

"Verily, the same it is, and has been, with all boards of committees, commissions and investigations, when the hard and loyal wage earner is made an object to maintain any army of officials."

PENNSYLVANIA

Anthracite

Scranton—Among the graduates of the night school classes of the Scranton Technical High School on Mar. 12, was William C. Jones, aged 66, employed as a miner during the day, who has completed the night school course with an average of 82 per cent. He intends to complete the high school course.

Williamstown—Rescue work in recovering the bodies of John Welker and Harry Lynch, miners, who were killed by an explosion of gas in the old slope of the Williamstown colliery on Mar. 10, was completed on Mar. 12. Tons of rock and coal had fallen on top of the unfortunate men, and the work of recovery was exceedingly difficult and dangerous. The little mining town feels shocked after this accident, coming so soon after two other miners lost their lives by an explosion of gas three weeks ago. This makes five fatal and fifteen nonfatal accidents this year for the community.

Pittsburgh—The Public Service Commission has announced that the date for the argument in the matter of the complaint against the Philadelphia & Reading and Pennsylvania railroads as to the cost of transporting anthracite coal from the mines to Philadelphia, which was fixed for Mar. 30, has been postponed until Apr. 13. The postponement is necessary for the reason that some of the attorneys interested in the case have made prior engagements to appear before the Interstate Commerce Commission on the 30th.

Mar. 25 has been agreed upon as the date for argument of the action in equity brought by the Peoples Coal Co., of Scranton, to test the constitutionality of the anthracite coal tax act of 1913.

Bituminous

Pottsville—Joseph Jones, a timekeeper employed by the Lehigh Coal & Navigation Co., at Coaldale, on Mar. 9, pleaded guilty to four charges of embezzlement and one of larceny and was sentenced to two years in jail. By means of fictitious names placed on the pay-roll, Jones, in eighteen months, defrauded the company of $5400, using the money to speculate.

Pittston—Several graves in St. John's Cemetery have been affected by a cave-in at No. 2 mine of the Pennsylvania Coal Co. The cave-in is 40 ft. in diameter, and, owing to the fact that the ground is still unstable, it is impossible to remove the bodies. Officials of the company admit that the whole cemetery is undermined.

Wilkes-Barre—By a decision of Judge Garman, of the Luzerne County Court, in the famous suit of the Pennsylvania Central Brewing Co., against the Lehigh Valley Coal Co., over the destruction of an artesian well the court refuses a new trial and judgment notwithstanding the verdict to the defendants, thus sustaining the verdict of $8000 given the Brewing Co. for the destruction of the well.

The case was one of the most unusual tried in the lower courts in some years and was based on a conflict of surface and mining rights, the right of the plaintiff to the water under the ground from a well sunk on its property as against the right of the defendant company to mine its coal under the ground regardless of the well.

WEST VIRGINIA

Charleston—A classification of the 23 fatal accidents occurring in the West Virginia field during the month of February shows that four occurred on the outside and nineteen on the inside of the mines. Death came to nine from falls of slate and coal; six from car and motor accidents; two from electrocution; two from explosions; two from falls in the shaft; one from machinery, and one from the kick of a mule. Compared with the record of 38 deaths of the month previous and that of 33 for February, 1913, the Department of Mines has every reason to be encouraged by this report.

OHIO

Columbus—Lake vessels owned by Ohio companies come within the scope of the workmen's compensation act, and if their employees who are hired in Ohio are victims of accidents which happen in waters beyond the jurisdiction of the state, they are entitled to recover from the Ohio State insurance fund. If an employee of an Ohio corporation which pays into the workmen's compensation fund is injured or killed while in the performance of his duty in another state, recovery may be had under the compensation act. Should the employee elect to sue for damages in the outside state the company would be allowed to use the same defense it would have if the action were brought in Ohio.

Urban—John Downey, a well known coal dealer of this section, recently was shot and killed by George Lee, a tenant in one of his houses following a dispute.

Massillon—The tipple and power house of the Massillon-Elm Run Coal Co. near here were saved from destruction by fire recently when a neighbor started the pumps and quenched the flames. The fire started from a miner's lamp.

KENTUCKY

Whitesburg—W. H. Potter, of Mater, Ky., near this place, has leased 400 acres of fine coal land to Louisville and Cincinnati promoters for immediate development. The property lies around the mouth of Boone's Fork, on the edge of the main coal field in that section.

Frankfort—The House Committee on Mines and Mining has reported favorably a bill fixing the salary of the Chief Mine Inspector at $3000 a year and creating two additional assistants.

Lexington—State Mine Inspector C. J. Norwood, Perry V. Cole and T. J. Barr, comprising the State Board of Examiners for applicants for mine-foreman certificates, have issued 23 certificates to those who successfully passed the examinations begun Feb. 23, as follows: First-class, George Coburn, McRoberts; G. H. Darbyshire, Jenkins; John E. Dent, McRoberts; David J. Llewellyn, Jenkins; M. B. Mitchell, Raymond; C. F. Rainey, Warren, and W. R. Rainey, Warren. Second-class, H. S. Adkins, Rigley; J. C. Angel, Bradel; F. L. Long, Lower Greasy; F. F. McCoy, Warren; J. Dunn, Van Lear; Herschel Poge, Beach Creek; W. A. Ross, Warren; John D. Simpson, Excelsior; C. C. Ward, Williamport; George C. Wolfe, Van Lear. Four other applicants received third-class certificates, entitling them to act as foremen only in nongaseous mines employing not more than 25 men.

INDIANA

Evansville—It is understood that M. L. Albers, of 1 Liberty Street, New York, is endeavoring to secure several of the mines which were recently reported as being under option to the Deep Water Coal & Coke Co., with the idea of operating them before the opening of the Panama Canal. Albers is said to represent a New York syndicate.

OREGON

Portland—Word was received here from Seattle, Mar. 10, that title to a coal claim near Glacier, Whatcom County, estimated of great value, has been awarded by the United States Land Office at that place to six joint claimants: Mrs. Mary Wheatmar, Seattle; John P. Stuart, Blaine, Wash.; Harry C. Smith, Clarence C. Keplinger and Joseph M. Frankvitz, Bellingham, Wash., and Douglas H. Hinton, Glacier, Wash. Each owns 160 acres of the land, which is located in the forest reserve, about 140 miles from Seattle. The claims were filed in 1909. In 1911 the government brought action to annul the claims on the ground that the land was chiefly valuable for timber and not for coal. The final hearing came up Mar. 10. State Geologist Henry Landee, president of the state university; F. R. Whitlock, consulting engineer, and Charles Newhill, efficiency engineer, testified that the coal found was pure anthracite.

MISSOURI

Webb City—One miner was killed and one seriously, but not fatally, injured, when the hoist at the Burt-Robinson mine broke on Mar. 12. The men dropped about 200 ft. Charles Tow, 30 years old, was killed, every bone in his body being broken. Lewis Harris, 25 years old, probably will recover.

Princeton—Drillers on the Kesterson farm struck coal at a depth of 470 ft. The vein was about 5 ft. thick, and covered with about 2 ft. of slate. R. H. Brennan has leases on the land, and must bore five holes, according to the terms of his contracts. Railroad connections and other favorable factors have directed the attention of a good many operators to the Princeton field.

KANSAS

Frontenac—A good deal of interest was aroused here recently when a miner found a nail imbedded in a lump of coal mined at a depth of 50 ft. The nail, which was 2½ in. in length, and rusty, gave no indication of how it found its way into the ground at that depth.

OKLAHOMA

Huntington—The Central Coal & Coke Co., of this place, through the influence of Robert Barr, superintendent, has furnished each of its mines with a first-aid outfit, consisting of bandages, splints and other essentials, to be used to relieve the suffering of injured miners as much as possible before bringing them to the surface.

Oklahoma City—Operators of Oklahoma left for Washington recently to confer with government officials regarding the sale of coal lands in the McAlester field on which leases are held. Of the 438,000 acres of segregated Indian land to be sold, 100,000 is held by operators under 30-year leases, of which 18 years is to run. The operators wish to retain the leases and to secure departmental regulations for the protection of the land, regardless of their disposition. Included in the committee was W. E. Beaty, of the Dow Coal Co.; Carl Sholz, Rock Island Coal Co.; and J. H. Hibbon, superintendent of mines of the Missouri, Kansas & Texas Ry.

FOREIGN NEWS

Brussels, Belgium—Seven miners were recently drowned in a mine at Bracquegnies, near here, by the bursting into one of the galleries of a subterranean stream.

Ekaderinoslav, Russia—Twenty-four men were killed in an explosion of gas in a coal mine here on Mar. 8, caused by a miner opening his safety lamp in a gas-filled chamber in order to light a cigarette.

London, England—Heavy orders for German coal were recently placed by one of London's large gas companies. In connection with this, it is interesting to note that Berlin gas companies are also users of English coal, shipments of which are frequently sent up the Rhine as far as Mannheim, passing on their way within a short distance of the Essen coal region, probably the most important coal district on the continent.

CONSTRUCTION NEWS

Adamson, Okla.—The Dow Coal Co. is sinking a slope mine here, and expect to sink another shortly, and also to install a shaft at Savanna.

Newark, Ohio—The Dixie Coal Co. has purchased a tract of land along the B. & O. R.R. tracks and will start at once to erect large coal pockets for retail purposes.

Coal Hill, Ark.—Rafter Coal Co. will develop 153 acres of coal property acquired here, with a daily output of 150 tons. This company was recently incorporated as the Peoples Coal Company.

Nashville, Tenn.—The St. Bernard Coal Co., of Earlington, Ky., which recently acquired the plant and business of the Pinner Coal Co., is planning the erection of two additional screening plants in Nashville.

Columbus, Ohio—The New Pittsburg Coal Co., of Columbus, has received word that the Pittsburg Coal Co. will soon start the erection of docks at Allouez, Wis., which will cost $500,000 and require two years to complete.

Wasioto, Ky.—The Asher Coal Mining Co., recently organized with $60,000 capital, are beginning work on a first-class mining plant, near Wasioto, on the Cumberland Valley Division of the Louisville & Nashville. T. J. Asher is managing the new operation.

Harlan, Ky.—The Cumberland-Campbell Coal Co., recently organized at Welch, W. Va., by James B. Flannigan, Welch; Ely L. Glade, Chicago; J. M. Clay, Louisa; and J. W. Waldron and T. J. Flannigan, Welch, will start a million-dollar operation on Martin's Fork, near here, where they will build two good-sized industrial cities. Work to start within two weeks.

Pound, Va.—The Indian Creek & Pound River R.R., an extensive lumber carrier, makes the announcement that the road will be extended from Pound down Pound River to a connection with the Carolina, Clinchfield & Ohio R.R., now being completed through "The Breaks." The extension will be about ten miles long and will pass through a rich coal and timber section.

Bethlehem, Penn.—The Lehigh Coke Co. will shortly begin construction of a $4,000,000 plant for the manufacture of coke and coal byproducts to supply the blast furnaces and foundaries of the Bethlehem Steel Corporation. When completed the plant will be the second largest of its kind in the world, consisting of 424 ovens with a capacity for carbonizing daily 5000 tons of bituminous coal.

Fleming, Ky.—The Mineral Fuel Co. are getting well under way in the construction of their third industrial mining city on Yount's Fork four miles from Fleming, several hundred hands being at work. Already mining operations have been begun at two of the company's mines in Fleming. Two more mines will be in readiness immediately. The coal tonnage will be largely increased by April 1.

Gate City, Va.—The Clinch Mountain & Southern R.R. Co., with headquarters at Abingdon, Va., announces the building of a coal and lumber road from Gate City to Abingdon, 20 miles, construction of which is to start by April 1. The road will tap a large part of the rich timber holdings of the Clinchfield Coal Corporation where developments will soon start in the coal and timber properties. Construction will be rushed.

Hazard, Ky.—The Haley Coal Co. will begin operations immediately upon a mammoth coal mining plant on Lost Creek, seven miles from the main line of the Lexington & Eastern R.R. in Perry county, and have arranged with the L. & E. to build a spur line to the new development, construction of which is to start at once. This, according to information, will be one of the biggest coal operations in Perry county.

Newark, Ohio—The announcement is made by the officials of the Pan-American Coal Co., of this city, that extensive repairs and improvements will be made at the mines of the company located in several different mining districts of the state. It is proposed to install the Marcus picking tables, similar to those in use at the mines of the Pocahontas Coal Co., at Coalwood, W. Va. The nine mines of the Pan-American Co. have a capacity of 1600 tons daily.

Philadelphia, Penn.—The Lehigh Coal & Navigation Co., of this city, will add to the equipment of its mines at Lansford, Penn., six 15-ton and nine 8-ton electric mining locomotives manufactured by the General Electric Company. New electrical equipment for the No. 5 shaft at this colliery includes a 150-hp. induction motor, three 500-kv.a. transformers, control equipments, switchboards and accessories, which will also be installed by the General Electric Co.

St. Louis, Mo.—At the instance of the Laclede Gas Light Co., a bill recently was introduced in the St. Louis council, providing for the condemnation of nine streets on which the company wishes to establish a coke-manufacturing plant at an estimated cost of $1,500,000. The streets involved lie south of Broadway and south of Catlan St. in South St. Louis, adjoining the River Des Peres. No payment in consideration of the vacation of the property is provided in the bill.

INDUSTRIAL NEWS

Vinita, Okla.—C. C. Jenkins recently opened a stripping mine of 4 ft. of coal at his farm, two miles northwest of here. Prospecting is being done in that section by others interested in the situation.

Virginia City, Va.—The Virginia City Colliery Co.'s plant here, recently purchased by C. W. Lambert and William T. Williams, is being revived and extended with all latest improvements in modern machinery. They will begin shipping coal by Apr. 1.

Viper, Ky.—G. H. and Kemper Brashear have purchased the old Brasher coal-land tract, on Mace's Creek, near here, and will put in a $50,000 coal development, beginning work Apr. 1. A 1-mile spur line of the Lexington & Eastern R.R. will be built to the property.

Birmingham, Ala.—Protest against increased rates on coal from the Birmingham district to Memphis, Tenn., by the Frisco lines has been filed with the Interstate Commerce Commission by the Empire Coal Co. of Birmingham. It is claimed that these rates are higher by 10 cents per ton than for the same distance from Kentucky and Illinois.

Fleming, Ky.—The Mineral Fuel Co. here will open and begin active mining operation in five new mines at Fleming, Haymond and Yount's Fork by Apr. 1, and the output will be about doubled from the company's mines. Increases will also be made from time to time during the spring and summer months. Contracts were closed a few days ago for the entire output of the company's plants.

Pittsburg, Kan.—The Cherokée & Pittsburg Coal & Mining Co. has been made the defendant in a damage suit for $500. The plaintiff is Matthew Knowll, a farmer residing near Pittsburg. Mr. Knowll alleges that failure of the mine owners to have the mine entries under the farm propped, has caused his farm to sag and give way in certain places. He asserted further that the farm is now unfit for raising crops.

Cherryvale, Kan.—Smelting companies of Kansas, many of which were practically put out of business by inability to get gas or oil for fuel during the past winter, are, in several instances, trying crushed coal successfully for this purpose. The Edgar Zinc Co., of Cherryvale, has spent $100,000 in installing coal-burning kilns, and has resumed capacity operations, under the personal supervision of President S. C. Edgar, Jr., of St. Louis.

Pittsburgh, Penn.—A deal was consummated on Mar. 13, for a consideration of $6,000,000, whereby H. C. Frick bought 10,000 acres of coal lands in Perry Township, Greene County, Penn., from J. V. Thompson, of Uniontown. The deal was closed after Mr. Frick had completed the arrangements for the sale of his property on Sixth Ave. and Cherry Way to the Fort Pitt Hotel Co. A splendid hotel of 900 rooms will be built by the Fort Pitt people on the site purchased.

Columbus, Ohio—A new operating and jobbing concern which has opened offices in Columbus is Hatton, Brown & Co., which has main offices at Roanoke, Va. The Western branch is in charge of F. G. Hatton, president of the company, who will divide his time between the Columbus and Roanoke offices. It is the first effort of the company to enter the Western field. The company has mines in the Clinch Valley, Va., and controls the output of mines in the Pocahontas field in West Virginia and in eastern Kentucky. Another product is Wise County coke.

Whitesburg, Ky.—Contracts closed with the Northwestern Fuel Co., of Minneapolis, Minn., following a recent visit to the mines of the Consolidation Coal Co. by a number of officers of that company, calling for immediate delivery of large quantities of coal, have resulted in renewed activity at the mines, which is hampered only by a lack of labor. Manager E. Drennen stated recently that there is a marked scarcity of efficient labor, which is the more regretted on account of the fact that the company proposes to open a number of new mines during this spring and summer. All plants now open will run full time for the remainder of the year, it is announced.

New Orleans, La.—In order to facilitate the handling of coal in cargo lots for export, the dock commissioners have under consideration a plan for setting aside a well equipped wharf for the handling of coal. This will be a part of the general movement to increase the exports through this port. With the river furnishing cheap transportation to the greatest coal fields of the country, the dock board is of the impression that the providing of proper facilities at this port will result in a large cargo movement, especially after the canal is opened. It is pointed out that during nearly half the year weather conditions at Hampton Roads interfere with the handling of coal, while here there would be no such interruption.

PERSONALS

Patrick Quinn, superintendent of the Sunshine mines at South Fork, Penn., is to be chosen head of the Sterling Coal Co.'s operations at Bakerton to succeed the late John B. Reed.

Benjamin Reene, recently rounded out his 55th year of service in the mines. Starting at the age of 11 as a slate picker, he worked his way up to a mine foremanship, and is at present with the Cranberry Colliery of A. Pardee & Co. in that capacity.

B. R. Smith has been appointed joint sales agent for the Corona Coal & Coke Co., the Birmingham Fuel & Iron Co. and the Roden Coal Co., succeeding the late John R. Ryan, general sales agent for the two former companies, who died about two weeks ago.

H. A. Rapelye was recently appointed Sales Engineer in the Pittsburgh District for the Terry Steam Turbine Co., of Hartford, Conn. His offices are in the Oliver Bldg., Pittsburgh, Penn. Mr. Rapelye has had a broad experience with turbine apparatus, and has been for the past two years the commercial engineer of a company prominent in the field of prime movers and auxiliaries.

H. J. Meehan, who was recently appointed general manager of mines for the Cambria Steel Co., began his duties on Mar. 14. Mr. Meehan was formerly Superintendent for the Lackawanna Coal & Coke Co., at Wehrum, Penn. During the four or five years that he was with the Lackawanna Co., he increased its output from 400 tons to 2500 tons daily. Mr. Meehan's headquarters are at Johnstown, Penn.

J. L. Forepaugh has been appointed lake freighting agent of the North-Western Fuel Co. with offices in Cleveland. He succeeds A. E. Williams, who resigned last month. Mr. Forepaugh was formerly a division superintendent for the Great Northern R.R., and of late has been a traffic manager for the North-Western Fuel Co. in St. Paul, Minn., where the company has its principal office. The appointment of Mr. Forepaugh was effective March 1.

OBITUARY

James Anderson, vice-president and general manager of the Pacific Coast Coal Co., and engineer of the Pacific Coast Coal Co., died on Mar. 13, at his home in Seattle. Mr. Anderson was 58 years of age, and was considered an authority on coal mining in the Pacific Northwest.

William R. Borders, president of the Bank of Sparta, of Sparta, Ill., and president and general manager of the Boyd Coal & Coke Co., of Sparta, was one of the victims of the Missouri Athletic Club fire in St. Louis, in the early morning hours of Feb. 9, in which 29 or 30 other persons lost their lives. Mr. Borders was 55 years old and a bachelor, and had interests scattered all over the country. At the time he was on his way to Texas, having stopped over in St. Louis for the night. The remains were taken from the ruins on the 13th and the burial held at Sparta.

Fred Rainecke, secretary, treasurer and general manager of the Reinecke Coal Co., of Madisonville, Ky., died at St. John's Hospital in St. Louis, Monday morning, Mar. 9, where he had been confined for some time. Mr. Reinecke belonged to a family of pioneer coal operators in the Illinois field adjacent to East St. Louis, and located there many years ago with his father and brothers. Some few years ago they sold their Illinois interest and removed to the West Kentucky field, where their mining interests are among the most prosperous and uptodate in the entire field.

NEW INCORPORATIONS

Burnwell, Ala.—The Burnwell Coal Mining Co., with operations in Walker County, has increased its capital stock from $50,000 to $100,000.

Logan, W. Va.—The Iroquois Collieries Co. has been incorporated here by Edward H. Jewett, Leonard C. Davies, Richard B. Chase, Ray Cook, and Walter C. McMahon. The authorized capitalization is $3000.

Hazard, Ky.—The Well's & Day Coal Co. has been organized here by P. G. Wells, J. H. Wells and R. F. S. Day, with capital of $50,000, for the purpose of developing the rich Perry County field, around Hazard. This field is attracting considerable attention.

Fort Worth, Tex.—The Strawn Coal Co. has filed articles of incorporation, the capitalization being placed at $500,000. The incorporators and directors, each of whom subscribed to $100,000 of stock, are Paul Waples, L. H. McKee, W. Burton, J. L. Johnson and A. Deffenbach. The company will mine and market coal in Tarrant, Palo Pinto and other Texas counties, with headquarters at Fort Worth.

Whitesburg, Ky.—The Letcher County Coal & Development Co. has been organized here by James P. Lewis, Martin D. Lewis, James H. Frazier, Whitesburg, and George Hogg, Roxana, Ky., with a capital stock of $100,000, fully paid in. The company owns large areas of fine coal and timber properties in eastern Kentucky and proposes to spend thousands of dollars in the development during the spring and summer months. James P. Lewis is president, and James H. Frazier, secretary and treasurer.

Coal Trade Reviews

General Review

Cancellations the rule in anthracite and trade marking time pending opening prices. Possibility of a suspension in the soft-coal fields already discounted. Contracts renewed on the same basis as last year, but subject to a change in the wage scale.

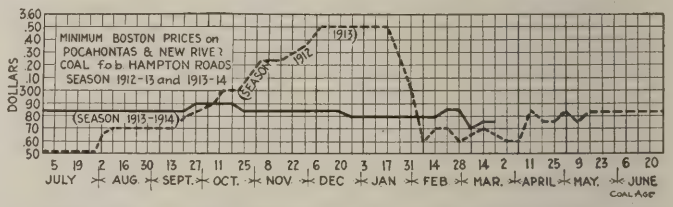
In spite of the fact that mining in the hard-coal regions is under heavily curtailed production, the anthracite agencies are being swamped with cancellations of March orders. Consumers and dealers have sufficient of the domestic sizes on hand to carry them over until the spring discount goes into effect, Apr. 1, and the market is flat and devoid of any interest whatever. The trade is at a complete standstill, and simply marking time pending the opening prices. Individual operators are always offering coal at the April circular, but the large companies are contenting themselves with making preparations for the spring and summer business, which promises to be heavy. It is generally agreed on all sides that stocks on hand are at an abnormally low level, and a sharp rush for coal is expected Apr. 1, with a consistently active business thereafter.

The possibility of a suspension at the bituminous mines, lasting from four to six weeks, seems to have been already discounted. General conditions are obviously unfavorable, and only a vigorous curtailment can prevent a price recession; should the price-level break, there is little hopes of it being restored during the dull period the trade is now facing. Some little contracting is being negotiated on the same basis as last year, but subject to any change in the wage scale. The Pittsburgh district reports prices steady, with mine operations at close to full rated capacity, due probably to a general stocking against a possible suspension and also in part to a slightly greater consumption; neither an agreement nor continuation of mining pending a settlement of the wage-scale controversy is anticipated.

While the price-level in Ohio is being well maintained, there is an entire absence of snap, although this should be ordinarily a boom period in trade circles. The domestic business is particularly hard hit, dealers attempting to clean up stock rather than accumulate surplusses. Hampton Roads prices are steady at the full circular, while loading at the piers is somewhat heavier and a further improvement is anticipated next week.

There has been a profitable business in the Southern domestic coals, as a result of the colder weather, but a decided slump is anticipated when the spring opening occurs; the steam trade is already demoralized, and many mines have shut down until conditions improve. As a result of the milder weather in the middle-western market, the domestic demand has dropped off almost entirely, and retailers are showing little disposition to accumulate surplusses against a suspension in mining Apr. 1. This also applies to the steam trade with the single exception of the railroads which are stocking heavily.

EASTERN MARKET



BOSTON

A dull period of 60 days or so still predicted. Less talk of concessions on contracts, while spot coal is practically at a standstill. Some demand for Pennsylvania grades but mostly for all-rail delivery. Water freights easy. Anthracite beginning to be loaded for April billing.

Bituminous—The general opinion of a fortnight ago that there would be little doing on contract business until after May 1 seems to be borne out by the state of trade so far this month. Aside from water freights being guaranteed at a minimum, there is little reason to suppose that any material concessions are being made from the $2.85 price f.o.b. Hampton Roads. If the price level should be reduced through over-anxiety on the part of any of the shippers it would be next to impossible to reëstablish the season basis in a year so dull as this promises to be. Spot coal is practically at a standstill, with no near prospect of improvement. New England buyers feel they can continue their waiting policy and perhaps make better purchases in May or June.

Only a relatively small volume of the Pennsylvania grade is coming forward in anticipation of a suspension in mining. Most of such supplies are coming all-rail; the tide-water market has shown rather less activity in that line. Shippers of the better known coals are sharing a fair amount of March business but the bulk of it is a hand-to-mouth matter.

Water freights are easy at 70@75c, Hampton Roads to Boston. The demand for tonnage is light, even some of the steamers being in the market for recharter. From New York for points on Long Island Sound rates are 45@50 cents.

Anthracite—Large dealers in the cities are running along on light stocks, hoping for early April deliveries. It is understood that the shipping companies have already begun to place barges for April billing. The volume of domestic sizes to be received here next month is expected to be heavy. The ice went out of the Sace River on Mar. 15, but the Penobscot and Kennebec will probably not open until Apr. 5 to 10.

There is some anxiety over the probable shortage in the supply of broken coal, and prices on that size are expected to be firm in all directions.

Current quotations on bituminous at wholesale are as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.90	2.92@3.02	
New York*	2.50@3.05	2.80@3.20	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.75@2.85
Boston†				3.78@3.83
Providence†				3.73@3.78

*F.o.b. †On cars.

NEW YORK

Bituminous trade fails to respond to the possibility of a suspension in mining. Spot market flat and little doing on new contracts. Nominal market on hard coal down to the April circular, and the trade marking time pending opening prices.

Bituminous—Contrary to what is normally the case, just before a possible suspension in mining, there is absolutely no snap whatever to the bituminous market. With the exception of some buying on the part of the Berwind Co., due probably to the delayed movement as a result of the inclement weather, there is practically no spot market whatever. This is rather remarkable in view of the fact that conservative interests look for a suspension of from four to six weeks, and it is evident that buyers are either skeptical of this or that such a condition has already been discounted.

Business on contracts is also coming in slowly, with prices usually on the same basis as last year, but subject to any increase in the wage scale. A large tonnage of Fairmount coal for lake shipping is reported to have been closed. Demurrage coal is well cleaned up locally, but the loading at South Amboy is still reported slow.

The market is not quotably changed, and we continue on the same basis as last week, as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; George's Creek, $3.15@3.25.

Anthracite—Hard-coal operations are heavily curtailed, while all agencies are being swamped with cancellations. The nominal market on the prepared grades is practically at the full April discount, rumors even being current to the effect that some of the larger companies are making such concessions; this is hardly possible, however, and more likely applies to orders being placed now for April delivery. There is plenty of individual coal, however, available at these figures.

As a rule, the steam grades are somewhat easier and more nearly normal, but the curtailment in mining is still resulting in reduced shipments, and there is an acute shortage in certain departments, notably pea and buckwheat, which are practically out of the market. The anthracite trade is now practically marking time, pending the spring opening, Apr. 1, at which time a heavy rush for coal is anticipated. In view of the reduced mining over the past few months, the feeling prevails generally that the stocks of hard coal are at an abnormally low point and an unusually active spring and summer business is anticipated. We quote the New York hard-coal market on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00		$5.05	
Egg	5.25	$4.90@5.35	5.30	$4.75@5.30
Stove	5.25	4.90@5.35	5.30	4.90@5.30
Chestnut	5.50	5.35	5.55	5.25@5.55
Pea	3.50	3.50@3.75	3.50	3.50@3.75
Buckwheat	2.75	2.75@3.00	2.70@3.45	2.70@3.00
Rice	2.25	2.25@2.50	1.95@2.20	2.00@2.40
Barley	1.75	1.75@2.00	1.70	1.60@1.90

PHILADELPHIA

Anthracite business flat. Demand for steam sizes good, but domestic grades quiet. Mining curtailed. Bituminous improving; demand about the same as last week, but at slightly better prices.

Anthracite—The market for anthracite, outside of the steam sizes, has fallen flat. The winter weather of the past month has been followed by almost spring temperatures, and as the householders have laid in sufficient supplies to carry them over until the opening prices, very little can be expected in the movement of the domestic sizes. The demand for steam grades still continues good, and the stocks of these grades have been largely reduced during the past three weeks. Curtailed mining has in part been responsible for the apparent shortage in these sizes, and in some cases, premiums have been asked and received.

The latter half of the month of March has always proved a fertile field for the individual operators who desire to continue work at their mines, and a large quantity of coal will doubtless come to this market, billed at the April figures. The large companies, however, still insist upon March prices, and content themselves with filling up their order books, and preparing for the heavy rush which is bound to take place on Apr. 1. A canvass of the situation finds the dealers in splendid shape to handle coal. Their calculations are doubtless made to have present stocks almost depleted by the opening of April, in marked contrast with last year, when considerable high-priced coal was carried over. The present outlook is favorable for a good, early spring business.

Bituminous—Slight improvement marked the bituminous trade last week. The demand was on about a parity with the week previous, but slightly better prices prevailed. The restricted movement of cars has doubtless caused this, but the end of the week finds traffic in much better shape. Restricted production, however, still obtains at many operations, and the fear of demurrage finds little coal standing at tidewater without shipping orders.

BALTIMORE

Car shortage is being severely felt, much to the surprise of the trade. Spot sales at tide exceed the mine prices. Anthracite demand shading off, but both branches busy on contracts for the new year.

At a time when the car movement is generally the best of the year, a shortage is beginning to develop. During the past week a number of mines in West Virginia and in western Pennsylvania reported inability to get empties as desired or to get their loaded cars on the move to terminal points. Whether the general retrenchment policies of railroads is responsible, or some other cause, the fact remains that the movement on the Pennsylvania, Western Maryland and Baltimore & Ohio is below the high standard formerly set. As a result there have been days when there was a considerable shortage of fuel at the piers here, and some shippers have been forced to purchase coal above the market price. The situation as to prices at the mines remains unchanged and the general market is still flat and uninteresting.

The anthracite men are feeling the effects of the spring shading off in demand, particularly in the household trade. Both ends of the business, however, are now busy on new contracts. A fair number of consumers are already in the field for long-term contracts, and the figures quoted are reported the same as those of last April. This is considered a good omen for a prosperous summer in the trade.

While principally interested with the future, there is enough spot business for the operators to maintain existing prices. West Virginia gas coals are commanding from 75 to 85c. with the steam grades around 90 to 95c. but the better grades are easy at from $1.15 to $1.30.

Heavy foreign loadings continue. A number of charters for foreign account, principally for South and Central America, and the Mediterranean, were announced during the week.

BUFFALO

Fair anthracite trade for the season and supply now decidedly light. Bituminous moving a little more freely. Coke not active. Some uncertainty as to new agreement.

Bituminous—The demand for all grades of bituminous is a trifle more active, with slack more so than sizes, which has been the case for sometime and is likely to continue. Shippers hardly know why this is except that there does not appear to be any made yet in connection with the lake trade. Slack comes into the lake trade indirectly in the preparation of three-quarter, which is the favorite size in that business.

Some of the mines have increased their output considerably to meet a sort of spasmodic demand from customers who are afraid that they will need more coal if the miners go out for any considerable time. Shippers are very cautious in predicting either a strike or a suspension. In view of this uncertainty, sellers and buyers are protecting their interests as best they can. There has been some delay on account of snow in the mining districts. Usually there is some activity on account of preparing for the lake trade, but now it is thought that the upper-lake docks may show large amounts unsold when the lakes open. Quotations are fairly firm at $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.50 for mine-run and $2.25 for slack, with Allegheny Valley about 25c. lower.

Coke—There is no stir in the coke trade. Here and there some shipper will discover an indication of improvement, but it is usually found to be temporary. The Buffalo price is based on $4.50 for best Connellsville foundry. Furnace coke is very dull, but stock is scarcer.

Anthracite—The demand is good, considering that April is so near at hand. The shippers look for a steady dropping off from this time on, but they are not anxious, for the supply is light and has been for some time. The mines have not run at all actively for a month or so past, due in part to the deep snow and there is also no particular reason for activity just now. Dealers in independent anthracite have cleaned up their supplies at circular prices and now look for a season of quiet.

There is no activity yet in Buffalo harbor. One shipper has taken some tonnage, but the ice is still heavy. As a rule, the lake shippers have little or no coal yet and they do not look for any right away.

CENTRAL STATES

PITTSBURGH, PENN.

Operations much improved and prices notably stiffer as result of impending suspension. Neither settlement or continuation of operations expected. Prompt coke continues easy and contracts moderately good.

Bituminous—The hardening in prices noted a week ago has continued, until the market is fairly steady around the $1.30 basis for mine-run. Slack can be picked up at the old price of 90c. in some cases, but sales at $1 and even $1.05 are not uncommon. Domestic 1¼ in. is going at $1.55@1.65. The higher figure is understood to be the minimum of the leading interest, an advance to that price having been made last October. Mine operations have improved and some of the large interests are now running practically full, while the Pittsburgh district as a whole is probably operating at fully 75% of capacity. A small part of the increase in demand is attributed to increased consumption, but the major part is ascribed to stocking up against a possible or probable suspen-

sion of mining Apr. 1. The market is quotable as follows: Slack, 90c.@1.05; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55@1.65 per ton at mine, Pittsburgh district.

The Interstate Joint Conference has been called by President John White of the United Mine Workers to meet in the Hotel La Salle, Chicago, Tuesday, Mar. 17. Coal operators refuse to make any predictions as to the outcome, but as a matter of fact there is little reason for expecting either a settlement or an arrangement to continue mining pending a settlement. The convention at Philadelphia lasted three weeks, or much longer than was expected. The Chicago convention has only two weeks and a day to the expiration of the present scale and it will probably put in all this time, since an adjournment with a disagreement would not look well before all the possible time had been used up.

Connellsville Coke—The market shows somewhat more strength. It has lately developed that several sales of round tonnages for second-quarter were made by the Producers Coke Co., in February, at $2, a price which has been withdrawn at least nominally. It is claimed that this interest is now sold up to an average operation of fully 50% of the plants represented, and will not sell any more coke except at an advance over $2. Other sellers are talking $2.10 and have some negotiations on. Prompt coke is quiet and is easier again, the stringency caused by bad weather being over. The market stands quotable: Prompt furnace, $1.90@2; contract furnace, $2@2.10; prompt foundry, $2.40@2.60; contract foundry, $2.40@2.60, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended Mar. 7, at 345,690 tons, an increase of 31,820 tons, and shipments at 383,842 tons, an increase of 42,058 tons. The shipments appear to have exceeded production by 38,152 tons, attributed to the movement of stock coke by the leading furnace interest.

TOLEDO

Market very quiet and demand for steam coal light. Circular prices holding well. Track coal strong among domestic dealers.

Although it was anticipated that purchasing agents for the large factories would by this time have been incited to provide reserve stocks in anticipation of a shutdown, conditions in the market are still unchanged. Reports state that in some instances reserves are being held that were bought several weeks ago when prices had slumped badly. This is, however, not general.

On the other hand, there is still an optimistic outlook regarding the situation. The weather is moderating each successive day and in consequence the immediate demand for domestics has weakened. The cold weather although of short duration, was still sufficient to enable the dealers to unload all of their yard stock. For the past week track coal has been in good demand to fill waiting orders. It must be an immediate sale or none at all and dealers do not seem inclined to await mine shipments.

COLUMBUS

Even with the wage agreement expiring there is no general stocking movement. Trade is quiet, although a considerable tonnage of steam grades is moving. Domestic trade has fallen off.

The coal trade in Ohio apparently has little snap at this time, although many contend that a suspension of from 30 to 60 days can hardly be avoided. Buying to guard against a suspension is not active and the market appears dull during a natural boom period. Prices are not being cut, however, to force trade and the general tone of the market is fair under the circumstances.

One of the worst features is the falling off in domestic demand. With the coming of higher temperatures the domestic producing section of the state is at a standstill. Dealers have been trying to clean up their stocks rather than to accumulate and this move has left them in good shape for the summer months.

The impression prevails that steam users, in case of a cessation of mining in Ohio will be able to get their fuel supply from West Virginia and there is a lack of buying for stocking purposes. Then, again, many of the steam consumers accumulated stocks during the past two months by permitting their usual requisitions to come forward, even when consumption was at a low ebb.

The railroad situation has improved to a certain extent, but the motive power on most of the roads is in bad shape and consequently the movement is not rapid. In the Hocking Valley district the output is estimated at about 75% of the average. In the Pomeroy Bend most of the mines worked full time and a normal production is recorded, but in eastern Ohio the output has been about 65%, and the same is true of the strictly domestic fields.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50 @ 1.40	.....	$1.50 @ 1.45	$1.50 @ 1.40
¾-inch	1.35 @ 1.30	$1.20 @ 1.15	1.35 @ 1.30	1.35 @ 1.30
Nut	1.25 @ 1.20	.....	1.30 @ 1.25	1.25 @ 1.20
Mine-run	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack	0.85 @ 0.80	.....	0.90 @ 0.85	0.80 @ 0.75
Coarse slack	0.75 @ 0.70	1.00 @ 0.95	0.80 @ 0.75	0.70 @ 0.65

CLEVELAND

Market suffering from a surplus of coal and spring-like weather. Retail trade at a low ebb and the wholesale has no outlet. Prices are running below cost in many instances.

All last week coal was a drug on the market. Stocking has been carried about as far as the manufacturers intend to go. The jobbers and operators have more real coal on hand than they can move and concessions are the rule rather than the exception. Monday the situation was worse than last week because of the large receipts. Youghiogheny slack was being offered at $1.95 by a local operator, who had a number of cars on track and he would have sold 5c. under that price to have moved it last Saturday.

As there are few boats available, it is not likely much, if anything, will be loaded until after the navigation season officially opens, Apr. 15, and really not before May 1.The attempt to charter tonnage for the entire season at 25c. to the fast docks on Lake Superior seems to have failed, and it is understood 27½c. is being offered. The fact that the shipper is willing to meet the vessel owners half way means none of the boats can be had at the lower rate and the prospects of a 30c. rate are good.

Reports received from Duluth-Superior state that the coal shipments during the first half of March have been normal. The February business was good because the temperature averaged ten degrees below normal. It is estimated by the fuel agent of one of the largest railroad systems in the Northwest that the docks at Duluth-superior are holding between 3,000,000 and 4,000,000 tons of coal.

Sales on the spot market were made at the following prices last week and Monday:

	No. 8	Middle District	Pocahontas
Lump, 1¼ in.	$2.05*	$2.00*	$3.10@3.15
Lump, ¾ in.	2.00@2.05	1.95	
Egg	.....	....	3.10@3.13
Mine-run	1.90	1.90	2.60@2.75
Nut	2.00@2.05	1.95	
Slack	1.85	1.75	2.25@2.35

*None on track.

DETROIT

Colder weather cleaned up stocks while delayed movement has restricted supplies and there is a somewhat better tone to the market. No general stocking in anticipation of a strike.

Bituminous—There is somewhat of an improvement in the local market, although the price level remains practically unchanged, except on some of the best grades. Slack is commanding a fair price, while the domestic grades are naturally somewhat softer as a result of the milder weather. The extreme cold weather of a few weeks ago did much to clean up the surpluses, and there is a rather slow movement on the railroads, which is keeping the tonnages available at a low point. Embargoes on the Big Four and congestions on other lines are reported.

While consumers as a rule are ostensibly refusing to buy, in anticipation of a shutdown Apr. 1, it is noted that there are some making extensive preparations against such a contingency. Contracts for the new year are being renewed on the same basis as for the last period, but it is reported that little new business has developed. The new circular on Pocahontas and New River is as follows: Lump and egg, April, $1.60; May, $1.70; June, $1.90; July, $2; August, $1.25. Mine-run from April to August is quoted as $1.25, and $1.40 beyond August.

Anthracite—The milder weather has resulted in a reduced demand for hard coal, and it is reported that there is considerable on demurrage.

Coke—The coke trade is quite active. The Semet Solvay Co. is reported considerably behind on orders, and although prices have not improved as yet there is a strong undertone. Connellsville foundry is quoted at $2.40, Semet Solvay at $3.25, and gashouse at $2.90, all f.o.b. ovens.

HAMPTON ROADS

Demand for spot coal improving somewhat and fair shipments being made on contracts. Principal foreign shipments during the week to Naples and Genoa.

Dumpings during the week have not been extra but are somewhat larger and it is believed conditions will greatly improve during the coming week. Barge and steamer loading for the New England market has been fair with some large shipments moving to foreign ports.

Prices on all grades still remain at circular, foreign shipments selling about $2.80 to $2.90 for New River and Pocahontas and the demand for these grades showing up considerably better. There is, however, practically no movement of either high volatile or prepared grades. Export coal for the week has moved to La Plata, Rio de Janeiro, Canal Zone, St. Lucia, Genoa, Naples, Kingston, Para, Ceres and Manos.

A record loading was made by the Norfolk & Western Ry. at their new pier at Lamberts Point on Mar. 9, when they loaded 6000 tons of cargo and bunker coal into the S. S. "Fedora" between the hours of 8 a.m. and 3 p.m. and it is believed that when this pier is working properly that much better work will be accomplished.

LOUISVILLE, KY.

Continued cold weather, with snow, has held business up with the retailers, but the advance of the season has cut down the demand with operators, who find orders diminishing. Weather is moderating.

Ane entirely unexpected snowstorm early last week resulted in a continuation of active business with retail coal dealers in this section, although hand-to-mouth buying was general on the part of domestic consumers. The retailers, in their turn, have resorted to the same plan, many of them retiring from the market with small supplies, purchased within the past week or so. In consequence, there is at present only a light movement, and operators find themselves in much the same condition as before the February cold snap came to their rescue.

Strike talk is common, and the hope is freely expressed that there will at least be a suspension in order to strengthen the market. Prices have not reached any higher level than that of the past few weeks, $1.50 being about the top of the market for first-class block. The steam market is in fairly good shape, with the lessening supply of screenings, 80 and 85c. being the price for the better grades of nut and slack.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM

Demand for lump coal much larger but steam coal quiet. Both furnace and foundry coke dull. Pig iron sales not so large as last week. Car supply ample.

The continued cold weather throughout the South has materially aided the lump-coal business, as there was practically no stocks in the yards, and, as the demand was quite heavy on the retail dealers, the operators reaped a substantial benefit. However, as practically all the cold weather is over, it is expected that lump will now take a decided slump until the spring buying sets in at the lower prices.

Conditions on steam coal are far from satisfactory. The coast business is not what it should be, and the market in general is greatly demoralized. Many of the mines are running on short time, and some are even shut down entirely until conditions change for the better. However, the operators expect an improvement within the next 30 days. With all the adverse conditions, however, prices on steam coal are holding up remarkably well.

The market on both furnace and foundry coke is still quiet, all orders being for small tonnage only. Blacksmith coal is in a satisfactory condition, the price being firm at $2 to $2.25 per ton f.o.b. mines. The furnaces report that a very small tonnage of iron was booked during the last week as compared with the last few weeks but that the price was slightly over the $11 mark for 2 foundry f.o.b. Birmingham. On account of the exceedingly small shipments of coal and coke, the car supply is not a factor at this time.

NEW ORLEANS

Continued low temperatures help move the domestic grades but heavier demand fails to increase prices. New wharf to handle cargo business being considered.

Owing to the mildness of the winter it looked, the first day of February, as if large piles of coal would be carried over. Most of the cold weather of the winter, however, has come since that date and stocks have been greatly reduced. Supplies are still above normal and there has been no tendency to depart from the reduced prices that went into effect shortly after the first of the year. With the passing of present cold spell there is little hope of any further domestic demand this winter. From now until the discount season there will be little activity in the local market. Despite the large stocks some coal is coming down the river from Pittsburgh and Kentucky.

CHICAGO

Moderate weather and market quiet but supported by fairly good buying for storage purposes. Producers are awaiting for Apr. 1 to develop some change in the situation.

The comparatively warm weather and the fact that winter is about over has resulted in quiet conditions. The retailer is not stocking up now, preferring to take his chances at getting coal at the April discount. Apartment houses, the principal users of smokeless, have been permitting their stocks to run down low, but strength is added to the market by the cleaning up of demurrage coal, with companies getting $1.40 for mine-run and $2.25 for lump and egg, with some shading on both figures. If mine-run is up to demurrage it has been disposed of as low as $1.25, while the forcing of lump and egg brings the price for the latter below $2.

The demand for Hocking has been unusually quiet with the price maintained at $1.50. The splint situation is still unsettled as the result of shipping this coal in open cars by consignment to Chicago. A large bulk of this grade has sold at from $1.40 down to $1.10 and $1, but the circular price is $1.50. Franklin County coal is selling at $1.50 circular when it is shipped direct from the mine, while coal up to demurrage is less than $1.25. The Carterville situation is practically the same with quotations of from $1.40 to $1.50. There is an active steam demand in the Springfield market and Indiana dealers are reaping the benefit of a strike scare. The coke market is rather soft for domestic but strong for the hard coke.

Prevailing prices at Chicago are:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.07@2.17	$2.55@2.65	$2.12@2.27	
Steam lump	1.97		1.97	
Egg		2.55@2.65		$4.30
Mine-run	1.87	2.20@2.25	1.87	3.45
Screenings	1.67@1.77	1.90@2.05	1.67@1.77	

ST. LOUIS

Railroads doing considerable stocking but the average steam consumers very little. No strike expected but a suspension of some duration anticipated.

The domestic demand has practically ceased, and few of the companies are laying in storage coal. During the past week, however, the railroads became open about their buying in both the Carterville and Standard fields, and a large tonnage is now moving for railroad storage. The crisis will come as a result of the conference in Chicago and it is impossible at this time to determine what action they will take. It is likely, however, that there will be no strike, but that there will be a suspension. This will cause a general advance in prices, on account of the certainty of having to place orders for storage coal.

The screenings market is in a healthy condition, Standard screenings selling at from 65 to 70c., and Carterville at from 85 to 90c., with indications that both grades may do from 5 to 10 or 15c. better almost any time. Otherwise there has been practically no change in prices and the washed market is still weak. The Nos. 3, 4 and 5 sizes are in good demand, with No. 5 at 75 to 80c., and Nos. 3 and 4 at $1.25 and $1.35. Nos. 1 and 2 are offered freely and hard to move at $1.25. With screenings at $1 this will open the way for outside coal from the Kentucky field, and the coming week may see considerable of this brought in.

KANSAS CITY, MO.

Arrival of spring weather has shut off buying. Mine operations reduced to 50% capacity.

The arrival of spring has tended to cut down demand from retailers. Dealers, while having light stocks on hand, are not inclined to order heavily in view of the warm weather, and operators of the Southwest must now rely on other than domestic consumption for business.

Operations at the mines have been reduced to about half time as the result of recent unfavorable developments. The prospects are for this average to be maintained for some time to come. No change has been made in quotations. Sales offices are still selling from track, but this method is likely to be eliminated in the immediate future.

OGDEN, UTAH

Market conditions weak. Spring weather prevailing from Omaha to Pacific Coast. Surplus of nut coal at mines. Quotations unchanged and unsteady.

The mines in Wyoming and Utah have reduced operations to summer basis on account of the weak market and the mine that is able to work half time is fortunate. The mild winter is being followed by an early spring and no doubt the market will continue weak for some time. At present there is a surplus of nut coal at the mines, but it is hoped the early spring will create a demand for this grade of coal as it makes a good warm weather fuel.

	California	Nebraska	General
Lump	$3.00	$2.75	$2.75
Nut	2.50	2.00	2.25
Mine-run	1.85	1.75	1.85
Slack	1.00	1.00	1.00

PORTLAND, ORE.

Winter's trade over and has been a poor year. But coal consumption on whole is increasing.

Winter is now practically over here. The weather has been unusually mild in the Pacific Northwest all winter and hence the demand for coal for domestic purposes has been light, although new uses for coal has probably resulted in an increase in the total consumption.

A regular line of steamers has been established between Portland and points in southeastern Alaska and it is expected that these steamers will call at the Vancouver Island collieries for return cargoes. This will probably affect the fuel situation to some extent here next winter. With freight rates more reasonable the demand for coal here will be increased, it is agreed by all dealers, for under existing conditions little fuel of quality is obtainable at less than $9.

PRODUCTION AND TRANSPORTATION STATISTICS

BITUMINOUS COAL MOVEMENT

The following is a summary of the movement of coal and coke over 13 principal railroads during December and the twelve months of 1913 in comparison with 1912, in short tons:

	December		12 Months ending December 31	
Anthracite	1912	1913	1912	1913
Baltimore & Ohio[1]	179,705	118,264	1,613,190	1,516,916
Chesapeake & Ohio[1]	1,541	681	23,450	16,545
Erie[3]	680,141	794,562	7,537,623	8,811,114
Pennsylvania[1 3]	1,036,717	1,012,125	10,312,348	10,711,335
Virginia[2 1]	103	86	283	1,045
Total 5 roads	1,898,207	1,925,718	19,486,894	21,056,955
Bituminous				
Baltimore & Ohio[1]	2,796,924	3,183,145	34,128,269	36,915,385
Buffalo, Roch. & P.[1 2]	719,733	816,981	8,289,296	9,723,992
Buffalo & Susq.[1 2]	138,944	141,895	1,530,441	1,787,551
Chesapeake & Ohio[1]	1,266,503	1,438,367	17,011,888	17,155,233

Pitts. Shaw & North[1 2]	2,004	.....	7,159	9,383
Western Maryland	5,927	4,801	70,351	73,346
Total 10 roads	2,500,902	1,827,967	27,202,978	27,696,763
Coal and Coke, 13 Roads				
January			16,421,839	18,936,646
February			17,787,331	17,546,496
March			19,483,025	17,631,346
April			13,429,367	16,850,695
May			15,635,568	18,986,790
June			16,702,153	18,580,366
July			16,635,448	18,704,713
August			18,396,247	19,718,850
September			17,432,358	19,046,247
October			18,712,657	20,611,176
November			17,815,767	18,931,169
December			17,929,632	18,225,750
Total, 12 months			206,381,392	223,770,244

[1] Includes coal from connecting lines.
[2] Includes company's coal.
[3] Does not include company's coal hauled free.

Note:—The Southern Railway hauled 373,994 short tons of bituminous coal during November, 1913, and 3,869,715 short tons during the 11 months ending November 30, 1913.

NORFOLK & WESTERN RY.

Following is a comparative statement of the N. & W. tonnage for February, 1913 and 14:

	Shipped		Tipple		Total	
Field	1914	1913	1914	1913	1914	1913
Pocahontas	869,596	793,880	16,691	17,158	886,287	811,038
Tug River	201,007	192,545	3,067	3,809	204,074	196,354
Thacker	191,755	252,527	6,473	8,955	198,228	261,482
Kenova	64,371	64,018	7,030	9,173	71,401	73,191
Totals	1,326,729	1,302,970	33,261	39,095	1,359,990	1,342,065

Shipments of coke, entirely from the Pocahontas field, were 64,610 tons in February of this year as compared with 121,058 last year.

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Mar. 1, as follows:

	Surplus	Shortage	Net*
New England Lines	128	0	**128**
N. Y.; New Jersey, Del.; Maryland; Eastern Penn.	12,243	0	**12,243**
Ohio; Indiana; Michigan; Western Pennsylvania	28,539	129	**28,310**
West Virginia, Virginia, North & South Carolina	5,372	900	**4,472**
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	4,543	23	**4,520**
Iowa, Illinois, Wis., Minn.; North & South Dakota	4,019	42	**3,977**
Montana, Wyoming, Nebraska	1,517	0	**1,517**
Kansas, Colorado, Missouri, Arkansas, Oklahoma	3,289	0	**3,289**
Texas, Louisiana, New Mexico	614	0	**614**
Oregon, Idaho, California, Arizona	4,558	200	**4,358**
Canadian Lines	0	0	0
Total	64,822	1,394	**63,428**

	Nov. 1	Nov. 15	Dec. 1	Dec. 15	Jan. 1	Jan. 15	Feb. 1	Feb. 15
Surplus	6,720	10,520	17,621	36,435	72,535	87,149	85,489	84,775
Shortage	12,595	8,477	5,095	2,295	57	789	102	239
Net*	5,875	**2.043**	**12,526**	**34,140**	**72,478**	**86,360**	**85,387**	**84,536**

***Bold face** type indicates a surplus.

FOREIGN MARKETS

GREAT BRITAIN

Mar. 6—Irregular conditions are again in evidence. Steamers are being much delayed by stormy weather, and stocks of coal are heavy. Buyers in a position to take immediate delivery, are able to secure easy terms for most qualities. Colliery owners regarding the difficulties as only temporary, are unwilling to modify prices for forward loading. Quotations are approximately as follows:

Best Welsh steam	$4.50	Best Monmouthshires	$4.14
Best seconds	4.38	Seconds	4.02
Seconds	4.14	Best Cardiff smalls	2.64
Best dry coals	4.38	Seconds	2.52

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are net f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days.

ITALIAN COAL CONTRACT

Contracts for supplying about 750,000 tons of coal for the Italian State Railways during 1914 have gone to Cardiff, Wales, and the price is to be $3.89 to $4.01 per long ton f.o.b. Cardiff. The coal is to be best Monmouthshire.—"Daily Consular Reports."

FOREIGN TRADE OPPORTUNITIES

The United States Consular Service reports opportunities in foreign coal markets as follows; complete details regarding different items can be obtained on application to the Bureau of Foreign and Domestic Commerce, Washington, D. C., by giving numbers:

Canada—It is reported that a bill was recently enacted by the Canadian Parliament to exclude French steam trawlers from ports in Canada where they now go to coal. If this law becomes effective, it is proposed to establish a coal depot for the trawlers, and it is possible that this depot will be supplied with coal from the United States. An American consul has already furnished some particulars in regard to American coal, but the administrator of the port desires to procure as soon as possible all available information regarding the price of coal f.o.b. Norfolk, under contracts calling for about 40,000 or 50,000 tons of coal per annum.—**No. 11,870.**

Europe—A member of a business firm in a European country informs an American consular officer that he desires to be placed in communication with American exporters of coal, with the object of representing them as agent. Correspondence may be in English. Prices, terms, discounts, etc., are desired. References can be furnished.—**No. 11,931.**

Index of Coal Literature

We will furnish a copy of any article (if in print) for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be sent with order.

BRIQUETTES

Fuel-Briquetting Investigations. C. L. Wright. Bureau of Mines, Bull. 58; 266 pp., illus.

The Briquet for Saving Fuel Waste. D. A. Willey. Coll. Engr., February, 1914; 2 pp., illus. 35c.

COAL DUST

British Coal-Dust Precautions. C. F. J. Galloway. Coll. Engr., March, 1914; 2½ pp. 35c.

French Coal Dust Precautions. P. Dunaime. Coll. Engr., February, 1914; 4⅓ pp., illus. 35c.

Wet-Peat Zones for Arresting Coal-Dust Explosions. R. Cremer. Iron Coal Tr. Rev., Feb. 20, 1914; ⅝ p., illus. 40c.

COKE

A Westphalian Byproduct Coking Plant which also Supplies Town Gas. (Abstract of Paper by L. D. Ford read before the North of England Inst. of Min. & Mech. Engrs.) Iron Coal Tr. Rev., Feb. 20, 1914; 1⅓ pp., illus. 40c.

A New Type of Coal Compressor. (Meguin's Magnetic Stamping Machine.) Gas Wld., Feb. 7, 1914; 1¾ pp., illus. 40c.

Coal- and Coke-Handling Machinery as Applied to Horizontal Retorts. (Discussion.) Gas Wld., Feb. 28, 1914; 2¼ pp. 40c.

Coke Oven Gas for Gas Engines. (Paper by Heinrich J. Freyn presented at the Feb. meeting of the A. I. M. E.) Iron Tr. Rev., Mar. 5, 1914; 2 pp. 25c.

Coke-Oven Gas for Power Purposes. Coll. Engr., February, 1914; 1½ pp., illus. 35c.

Byproducts vs. Beehive Coke Ovens. Henry S. Geismer. Coal Age, Feb. 28, 1914; 2 pp. 10c.

Metallurgical Coke. A. W. Belden. Bureau of Mines, Tech. Paper 50; 40 pp., illus.

The Automatic Control of Byproduct Coke-Oven Plants—III. A. Thau. Gas Wld., Feb. 7, 1914; 2 pp., illus. 40c.

DRAINAGE, PUMPING, ETC.

New Pumping Plant at Burley Colliery. (The new pumps are installed in duplicate in a roomy pump house about 90 yd. from the pit-bottom, taking the place of the steam driven pumps installed at the pit-bottom and delivered to a lodgment, the final lift being made by a Cornish pump installed on the surface.) Iron Coal Tr. Rev., Jan. 30, 1914; ⅝ p., illus. 40c.

Unwatering Old Workings at Middletown Colliery. (Paper by Cecil Hinchliffe read before the Yorkshire Branch of the Natl. Assn. of Coll. Mgrs.) Iron Coal Tr. Rev., Jan. 30, 1914; 3 pp., illus. 40c.

The Oneida Drainage Tunnel. A. H. Lewis. Employees' Mag., January, 1914; 3½ pp., illus.

ELECTRICITY

A Draw-Out Mining Switch Pillar. Coal Age, Feb. 14, 1914; 1¾ pp., illus. 10c.

Direct-Current Fields. (Discussion of some of the difficulties encountered in the operation of direct-current machines and some emergency cures.) Coal Age, Feb. 28, 1914; 1 p. 10c.

Electricity in Mines. (Paper read by Robt. Nelson before the No. Staffordshire Inst. of Min. & Mech. Engrs.) Coll. Guard., Feb. 6, 1914; 1 p. 40c.

Electricity in Mining. E. B. Wagner. Employees' Mag., January, 1914; 1½ pp., illus.

Explosion-Proof Mining Switch Gear. Coal Age, Feb. 28, 1914; 1 p., illus. 10c.

Hydro-Electric Power for West Virginia Collieries. C. A. Tupper, Coal Age, Feb. 7, 1914; 3 pp., illus. 10c.

Purchased Power and Bituminous Coal Mining. A. E. Rickards. Coal Age, Feb. 7, 1914; 5¼ pp., illus. 10c.

Speed Control of Electrical Motors. Coll. Guard, Feb. 13, 1914; 2 pp., illus. 40c.

The Action of Acid Mine Water on the Insulation of Electric Conductors. (A preliminary report.) H. H. Clark and L. C. Ilsley. Bureau of Mines, Tech. Paper 58; 19 pp., illus.

The Application of Electric Motors to Shovels. H. W. Rogers. Bull. A. I. M. E., February, 1914; 10½ pp., illus.

Use of Alternators in Parallel. C. A. Tupper. Iron Tr. Rev., Mar. 5, 1914; 8 pp., illus. 25c.

EXPLOSIONS

Auckland Park Colliery Explosion. Jas. Ashworth. Coll. Engr., February, 1914; 1⅝ pp. 35c.

Explosions in Mines. (Lecture by Prof. H. B. Dixon.) Coll. Guard., Feb. 13, 1914; ⅝ p. 40c.

Stone-Dusting at Bentley Colliery: Report to the Doncaster Coal Owners' (Gob Fires) Committee. (Paper read Feb. 21, 1914, by Robt. Clive before the Midland Inst. of Min., Civil & Mech. Engrs.) Iron Coal Tr. Rev., Feb. 27, 1914; 5 pp., 7 tables. 40c.

The Automatic Distribution of Stone Dust by the Air Current. (Abstract of paper by H. W. Halbaum read Feb. 14 before the North of England Inst. of Min. & Mech. Engrs., and Discussion.) Iron Coal Tr. Rev., Feb. 20 and 27, 1914; 2½ pp., illus. 80c.

The Explosion at Ravenwood, Colo. Samuel Dean. Coal Age, Mar. 7, 1914; 1½ pp., illus. 10c.

The Senghenydd Disaster. (Continuation of inquiry conducted by the Home Office.) Coll. Guard., Feb. 13 and 20, 1914; 3 pp. 80c.

FUEL TESTING

Coal and the Chemistry of its Carbonization. (Paper read by Dr. John Harger before the Liverpool section of the Soc. of Chem. Indus.) Gas Wld., Feb. 14, 1914; 1½ pp. 40c.

Miscellaneous Analyses of Coal Samples from Various Fields of the United States. U. S. Geol. Sur., Bull. 531, 1913; 4 pp.

The Microscopical Examination of Coal, Especially in Respect to Spontaneous Combustion. (Address by James Lomax before the Lancashire Branch of Natl. Assn. of Coll. Mgrs. and Discussion.) Iron Coal Tr. Rev., Feb. 27, 1914; 1⅝ pp. 40c.

GENERAL

Alaskan Coal Fields; Their Possibilities and Their Plight. J. Esdaile Florance. Eng. Mag., March, 1914; 10 pp., illus. 35c.

Coal at Horseshoe and Jerusaleum Valley, Boise County, Idaho. C. F. Bowen. U. S. Geol. Sur., Bull. 531, 1913; 6 pp., illus.

Coal Resources of Cowlitz River Valley, Cowlitz and Lewis Counties, Washington. A. J. Collier. U. S. Geol. Sur., Bull. 531, 1913; 7 pp., illus.

Coal in the Tertiary Lake Beds of Southwestern Montana. J. T. Pardee. U. S. Geol. Sur., Bull. 531, 1913; 15 pp., illus.

Mines and Mine Management: Past and Present. (Paper by John McLuckie read before the Scottish Branch of Natl. Assn. of Coll. Mgrs.) Iron Coal Tr. Rev., Feb. 20, 1914; 1¼ pp. 40c.

Prospects for Workmen's Compensation in Kentucky. G. D. Crain, Jr. Coal Age, Feb. 28, 1914; 1½ pp. 10c.

Status of the Coal Industry. (Address by Thos. L. Lewis at the banquet of the Coal Min. Inst. of Amer.) Coal Age, Feb. 21, 1914; 2 pp. 10c.

Surveying Methods of the Consolidation Coal Co. A. W. Hesse. Coal Age, Feb. 21, 1914; 3 pp., illus. 10c.

The Value of a Technical Training to Underground Workmen. (Paper read by Prof. W. H. McMillan before the Natl. Assn. of Coll. Mgrs.) Coll. Guard., Feb. 13, 1914; ¾ p. 40c.

Use and Abuse of Wood in Anthracite Mining. (Abstract of paper by E. E. Reuter read before the recent meeting of the Panther Valley Min. Inst.) Coal Age, Feb. 21, 1914; 3¾ pp., illus. 10c.

GEOLOGY

The Barber Coal Field, Johnson County, Wyoming. Carroll H. Wegemann. U. S. Geol. Sur., Bull. 531, 1913; 21 pp., illus.

The Cerrillos Coal Field, Santa Fé County, New Mexico. Willis T. Lee. U. S. Geol. Sur., Bull. 531, 1913; 27 pp., illus.

The Coaldale Coal Field, Esmeralda County, Nevada. J. H. Hance. U. S. Geol. Sur., Bull. 531, 1913; 9 pp., illus.

HOISTING AND HAULAGE

Methods of Haulage in Coal Mines. J. Shanks. Can. Min. Inst. Bull. No. 23; 14 pp., illus.

Types of Electric Winding Engines. L. F. Mitten. Coal Age, Mar. 7, 1914; 4¼ pp., illus. 10c.

The Carron Haulage Gears. (The two illustrations show an endless rope haulage gear, which can be separated into two haulages and worked independently if desired, and a belt-driven double endless rope haulage.) Coll. Guard., Feb. 13, 1914; ⅓ p., illus. 40c.

The Care of Wire Rope. Employees' Mag., January, 1914; 1¾ pp., illus.

Loading Coal on Warrior River at Holt, Alabama

Large Hoist Installation

Small Hoist Installation

Westinghouse Hoist Installations
Both Large and Small

The motors and control of Westinghouse Electric hoist installations, designed especially for your service, have embodied in their design features that assure

Maximum Output Under All Conditions

Liberal design of motor makes it possible to hoist increased loads for a long period to make up for time lost in delivering coal, or ore, to the foot of the shaft.

Reliability

Reliability means continuity of service, assuring against loss due to reduced output caused by motor or control trouble.

Ruggedness

The first two points are dependent upon ruggedness of mechanical and electrical construction.

Efficiency

Power consumption per ton output is an important factor. Westinghouse high efficiency means low operating costs.

Safety

All Westinghouse hoisting installations are designed with control arranged to prevent accidents due to overwind, failure of power and errors in judgment of the operator.

Our specialists in mining equipment will be glad to assist you in selecting the proper equipment for your mines. Their services are at your disposal if you will write to the nearest office listed here.

VOLUME 5 MARCH 28, 1914 NUMBER 13

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED

*Illustrated Article

FOREWORD: *Page* 513

The Rover. Poem by Berton Braley.

IDEAS AND SUGGESTIONS: *Pages* 514-515

Converting the Foreman to the "Safety-First" Idea. The author points out the tendency of the busy mine foreman to neglect the "Safety-First" idea, until converted to it by the occurrence, under his charge, of some preventable accident. Sim C. Reynolds. COAL AGE, Vol. 5.
*A Built-Up Gin Pole.

*A LARGE KOPPERS' REGENERATIVE COKE-OVEN PLANT IN GREAT BRITAIN: *Pages* 516-517

A description of one of the largest retort-oven installations in England, with notes on the advantages of the Koppers' process. It is claimed that 25 million tons of coal per annum are consumed by this method. COAL AGE, Vol. 5

*THE STONEGA PLANTS IN WESTERN VIRGINIA: *Pages* 517-518

The plants at Stonega are among the finest in the State of Virginia.

*AUTOMATIC LIGHT SWITCH SIGNAL: *Pages* 518-519

SAFE BOILER SUPPORT: *Page* 519

KING COAL: *Page* 520

Poem by Robt. H. Wilson.

INCREASE IN BALTIMORE HARBOR FACILITIES: *Page* 520

*DWELLING HOUSES AT THE L. C. & N. CO.'S NEW HAUTO PLANT: *Pages* 521,522

The gradual leaning toward better construction of workingmen's quarters is becoming more noticeable each year. It is generally conceded that comfortable houses do much to attract and hold a more desirable class of men. Edw. L. Kellogg. COAL AGE, Vol. 5.

*THE SCOTTISH COAL PORTS: *Pages* 522-523

AUTOMATIC STONE DUSTING: *Page* 523

EXAMINATION QUESTIONS WITH ANSWERS: *Page* 540

COAL AND COKE NEWS: *Pages* 541-544

*MINE OF BIRMINGHAM FUEL CO. AT TOWNLEY, ALA: *Pages* 524-527

A description of the Townley mine: its position, equipment, working methods and output. COAL AGE, Vol. 5.

ANTHRACITE COAL AND THE PUBLIC: *Page* 528

*HALF-MILLION DOLLAR EXPERIMENT STATION FOR U. S. BUREAU OF MINES: *Page* 529

*A NEW TYPE OF AUTOMATIC DUMP CAR: *Page* 530

THE SITUATION IN LABOR CIRCLES: *Page* 530

EDITORIALS: *Pages* 531-532

Miners' Union Opposes National Guard—Religion and Coal Mining—Playing to the Grand Stand—The Union—The Chief Cause of Mine Accidents.

SOCIOLOGICAL DEPARTMENT: *Pages* 533-535

*Method of Rendering First Aid:
A discussion of the most effective methods of rendering first aid to the injured in the more frequent types of mine accidents—as the breaking of a limb or the back—and practical suggestions regarding the best procedure in event of such accidents. A. S. Snyder. COAL AGE, Vol. 5.
*A Sunday School at Palos, Ala.

The Modern Guarantee

The Weekly Ad-Talk Page

"When a man writes his name on his goods, he thereby endorses them," says one of the Curtis Publishing Company's Advertisements.

"Then by advertising he puts a heavy investment behind that endorsement. He promises to be responsible.

"He separates himself altogether from the manufacturers who will not put their names on their handiwork, but send it out into the world like an anonymous letter, for which no one can be held responsible.

"The manufacturer who, by advertising, has given the purchaser a bond dare not take liberties. He must fulfill every expectation that his advertising may have aroused or lose part of his investment. He must keep up the quality. He must make the goods make good."

There is a world of truth in these words. Unless the advertiser keeps up the quality, unless he makes his goods make good, he forfeits his bond, he will not survive; because no advertiser is any better than the goods he has to sell.

Are you taking up the proffered bond—the bond offered to protect you? Are you using these weekly messages the advertisers are putting out to the fullest advantage?

Are you getting their weekly helps and hints that suggest new and various ways to solve your problems? Are you taking advantage of the valuable literature some of these advertisers offer to put in your files, gratis? Are you buying equipment that has the *public* endorsement of the manufacturer?

Your answer, sir, determines whether or not you are getting *full* value out of your subscription to Coal Age.

Again, therefore, let us add: If you are not an ad follower, become one *now*; because it pays.

COAL AGE

Vol. 5 NEW YORK, MARCH 28, 1914 No. 13

The Rover

By Berton Braley

Written expressly for Coal Age.

I've mined in France an' I've mined in Wales
An' I've mined n Russia, too,
An' I've heard all kinds of miner's tales
From many a husky crew;
In mines that's shallow an' mines that's deep,
I've drilled in the good black coal,
But there ain't no job that I seem to keep,
For I've got a rovin' soul!

There's some men loves a wife an' home
An' children four or five,
But something makes *me* want to roam
As long as I'm alive,
So I gets a job an' I works away
For mebbe a month or so,
Then I goes to the office to draw my pay
An' off on the trail I go.

There's a lot of places I've never seen,
That I kinda want to see,
So I hits the grit with an ardor keen
An' a heart that's light an' free,
I just can't stay in the same old place
A-seein' the same old things,
So I moves along at my own sweet pace
An' takes what my fortune brings.

Wherever there's coal that men must dig
I'm sure to get a job,
So I moves around in the world so big
As long as my heart can throb;
I swears that' I ll quit it now an then,
But I gets the same old call,
For the earth is full of mines an' men,
An' I want to see them all!

Ideas and Suggestions

Converting the Foreman to the "Safety-First" Idea

By Sim C. Reynolds*

SYNOPSIS—The author points out the tendency of the busy mine-foreman to neglect the "Safety First" idea, until converted to it by the occurrence, under his charge, of some preventable accident. He further indicates the necessity of putting the foreman, as, likewise, the miners, on guard before, not after, such an occurrence; and suggests, as a preventative, the practice of photographing the conditions surrounding an accident and distributing copies among all persons likely to be affected by a similar accident.

A foreman of one of the northwestern ore mines was showing the writer—whose business happened to be the looking up of dangerous conditions—through his concentrating plant. In that part of the establishment there were a number of belt-driven machines in operation washing ore. The larger-sized belts were guarded, but those of four or five inches or less were not. Having this matter brought to his attention the foreman in question said that it was his opinion that placing guards about such belts was an entirely superfluous precaution, and no arguments to the contrary that the writer could think of changed that opinion, although in other essential features concerning safety he was perfectly reasonable. He seemed to look at the subject from the same point of view that it is seen by many others; that the larger possibilities of creating accidents should be closely looked to, but that the smaller things are too trifling to demand much care.

Belated Conversion

In less than ten days from that time this foreman was thoroughly converted to the entire program of "Safety First," but in a way that is altogether too common. The poor fellow who accomplished the missionary work in this case did so by having an arm torn off at the shoulder —a tragic conversion, but decidedly efficient, as later events proved. As many another has done, this foreman has swung to the other extreme, and insists on the utmost measures of safety being taken by all under his charge. But who shall say but the price paid for that conversion was not too high, particularly when it might have been discounted by a little foresight and care regarding the so called little things.

This incident recalls another which, still more tragically, made a convert of a mine foreman to the "Safety First" idea. It happened at a mine not fifty miles from Pittsburgh. In order to conserve the lives of the employees, the Department of Mines had issued an order that all electric currents should be kept off the wires running into the mine, while men were being hauled to their work by mules over the electric haulage road. This was obviously a very necessary precaution, since the same state wrongly allows each workman to take with him into his working place as much as 25 lb. of powder—sufficient to last a week.

The particular morning when this accident happened, cutting was behind, and three or four machines were kept running right through from the night shift, which, of course, necessitated the current being left on the feed line in violation of the state rule. A switch, situated at the mine entrance, made the connection between trolley and feed lines, and on this occasion somebody had closed the switch for the purpose mentioned. One of the miners, sitting with others in a pit car waiting to be pulled into the mine, had a full keg of powder under him. Another came along with an 8-ft. drill, and in putting it into the car made a connection between the wire and the keg by means of the draw-bar, with the result that four men were instantly killed and a dozen others maimed for life. The very thing which the state department had anticipated had happened. The mine foreman at that pit now insists on carrying the "Safety First" idea to the limit of precaution insofar as concerns this particular matter. Not only does he not allow current to be on the wires while men are being hauled in, but also has the generator shut down until all danger is over from that source. But again may we not ask if the cost of converting him was also too high, particularly since it, too, could have been averted by a little more care regarding details.

Greater Responsibility with the Foreman

Statistics compiled by the Federal Bureau of Mines attribute the larger portion of all accidents in industry connected with mining to the carelessness of the miners themselves, and the figures are no doubt correct as a whole. Yet, to cut down this spirit of recklessness, which is universal wherever public work is carried on, and not only in coal mining as some may think, we have got to turn the man in direct touch with the workmen into a "Safety First" enthusiast, particularly when that man is the foreman of a mining plant, because he is, more so than any other in the industry, the individual on whose shoulders the chief responsibility rests for accidents that occur at his mine; and secondly, because the men at the great majority of pits get their orders direct from him, or from the fireboss through him. His attitude with regard to the "Safety First" idea will inevitably be reflected in the attitude and actions of his workmen, and they will be more or less earnest and serious in this respect in proportion as they see him earnest and serious in carrying out this idea in all things. It is thus that the foreman or superintendent who is deeply imbued with this chiefest of industrial ethical ideas, which, from a present-day intermittent thing, will, we believe, in time become an industrial institution, unconsciously communicates his care and caution to all with whom he comes in touch. Hence the importance of his being converted first.

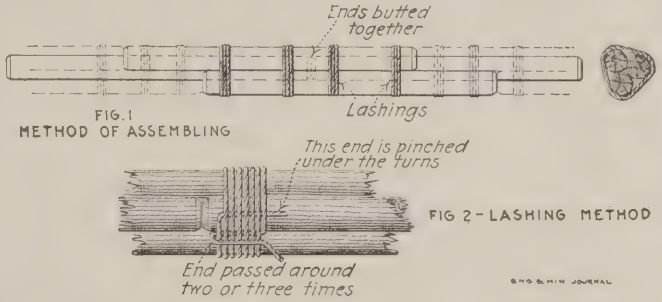
*Inspector, Aetna Life Insurance Co., Hartford, Conn.

Accidents Rarely Repeat Themselves

From an unusually extensive experience along the line of dangerous work in mines, the writer is convinced that, as a rule, accidents do not repeat themselves. I mean by that, that if a foreman has a driver crushed between a car and rib because of insufficient space for clearance he does not usually have that kind of accident happen again, at least not soon nor in the same place. His attention, because of that accident, is centered on the *cause* of it, and precautions are immediately taken to prevent the like occurring elsewhere. It follows that if the interest of the foreman can be obtained beforehand in a like regard, much good will result.

Many methods have been put into practice with more or less success in efforts to accomplish this. One large corporation in the bituminous field has illustrated talks given frequently in its various mining camps. Moving pictures showing the right and the wrong way of doing things, the conditions which lead up to accidents, are pictured and explained not only to officials but to all the workmen. It is the author's belief that attendance at such classes should be made compulsory, particularly with regard to the more ignorant workmen. Other companies issue illustrated pamphlets on safe management to its mine officials, and again others have appointed "Safety Directors" and "Company Inspectors" whose duty is solely to ferret out dangerous conditions and spots. This is as it should be at all plants, for the very obvious reason, which every mine foreman will readily agree with, that in most mines the foreman's attention is expected and demanded to the limit of his time and ability in the getting out of the largest possible tonnage, and, regardless of his attitude toward the idea of safety, he has not much time to devote to it. The larger companies are in many instances going fully into this, but no company is too small to not admit of some work along this line. In fact it is just as essential to the welfare of the industry as a whole that the small companies carry out the "Safety First" idea according to their means as it is for the larger companies to do so. The lives and health of the fifty or one hundred men employed in the little mine, should be, and are, equally as valuable as the same number multiplied several times over in the big plant. The reduction of mortality and liability for accidents will be in direct proportion to the interest taken in safety inspection at any mine, whether it be large or small.

Photographed Accidents Good Educators



It occurs to the writer that an excellent plan to follow, in keeping before the mine officials the necessity for safety measures, would be in event of an accident—especially a fatal accident—to have photographs made of the conditions leading up to the accident, and of the place where it occurred, and copies sent to all interested parties at the company's various mines. A good series of photographs will vividly show and silently yet eloquently explain to even the foreign miner who cannot speak a word of English, what caused a man to be killed at that place, no matter whether the accident occurred between a car and rib, under draw-slate, by a fall of coal, or at any other of the numerous death spots that are in every mine. In the case of the more common form—death by fall of roof—a picture showing where the post should have been set which would have prevented the fatality, would help much to keep the matter pertinently before the minds of the men who can in a great measure increase or reduce these accidents. If the death or accident happen through an electric wire being too low, a picture taken before it was raised or guarded, would, in some instances, tell the story better than words. The pictures could be accompanied by text, when deemed essential to the purpose, explaining what should have been done to obviate such accident. They would certainly be of great value in bringing before the other fellow the possibility of the same thing occurring at his mine, even though he may have been so fortunate as to not suffer any accidents of a similar nature for some time.

A Built-up Gin Pole

By A. Livingstone Oke*

It frequently happens, where timber is scarce, that a gin pole or other long timber is required larger than any single stick on hand. A method of building one from short lengths of either round or square timber is exhibited herewith.

The poles are laid up in threes, the ends overlapping, as shown in Fig. 1, with a lashing on both sides of each

Three Round Timbers Lashed together for a Gin Pole

joint; the number of turns of rope used depends on whether the pole has to sustain merely a thrust, as in a gin pole, or is to be employed for work in which it will be subjected to bending stresses. In the latter case, both the strength of the ropes, the number of turns and the tightness with which they are put on, must all be increased. If the poles available are all of the same length, but of different diameters, some care must be used in matching the sizes at different points in the length of the built-up pole, keeping the stouter ones together and gradually tapering to the smaller end. Poles may also be built with more than three members, but this number is the more satisfactory, when possible, as it makes a three-point support inside and prevents transverse movement.

Fig. 2 shows the proper method of lashing; several turns of small rope are to be preferred to fewer turns of a larger rope. One end of the rope is pinched under the turns and finally the free end taken around these by passing through several times, as shown, and the whole drawn up tight. To tighten the lashing further, short lengths of smaller rope may be passed around the turns on the other two sides as well and drawn as taut as possible.—*Engineering and Mining Journal.*

A Large Koppers' Regenerative Coke-Oven Plant in Great Britain

SYNOPSIS—A description of one of the largest retort-oven installations in England, with notes on the advantages of the Koppers' process. It is claimed that 25 million tons of coal per annum are consumed by this method.

One of the largest British coke-oven plants is at the Middlesbrough Works, of the Cargo Fleet Iron Co. The Koppers' Coke Oven & Byproduct Co., of Sheffield, are just completing for this firm a third battery of 50 regenerative coke ovens and in addition to these, the whole of the byproduct plant has been remodeled. The old plant is to be abolished, and a complete new one installed,

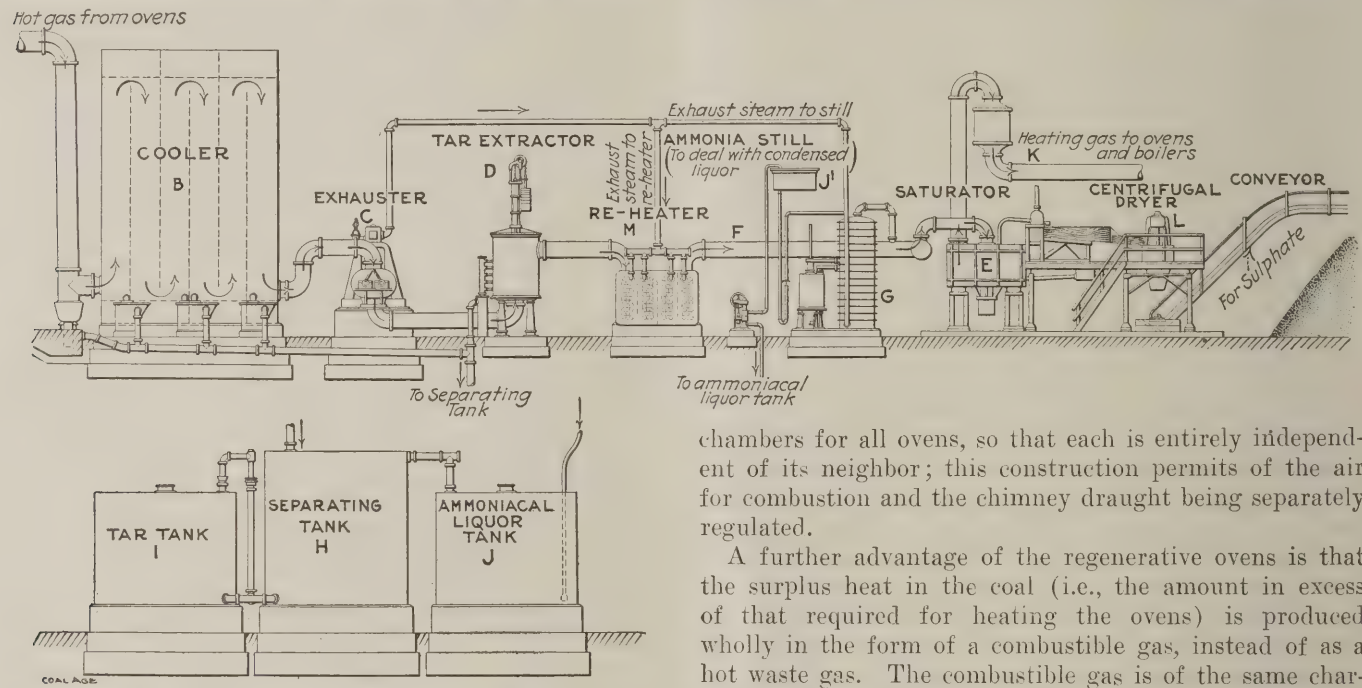

DIAGRAM ILLUSTRATING THE KOPPERS' DIRECT-RECOVERY SYSTEM FOR AMMONIA

working on the Koppers' patent direct-recovery principle for the recovery of tar and sulphate of ammonia. Up to the present time, benzol has not been saved but a plant is now being erected for its recovery from all the 150 ovens.

SOME ADVANTAGES OF THE KOPPERS' PROCESS

The Koppers' oven is of the vertical-flue type and possesses special features not to be found in other ovens, more particularly as regards the arrangement of the heating flues and regenerators and the facilities for inspection. The gas and air for combustion are separately distributed on each side and along the whole length of the oven and combustion takes place in each vertical flue. Each oven wall is formed of about 30 vertical flues, there being a gas jet in each flue: all ovens are heated at about 60 points.

At the top of the ovens and over all the vertical flues, openings are provided for giving access for inspection and regulation. Simple means are also provided for the regulation of combustion in each flue, which is such that it is easily possible for the walls to be uniformly heated from end to end. It is this ease of regulation which distinguishes the Koppers' oven from all other types. Uniformity in the heating of the ovens, not only results in the production of a homogeneous coke but enables the coal to be burnt off more quickly, besides which it effects great economy in the consumption of gas. It is owing to this latter economy that the surplus gas from the Koppers' oven is probably greater than that obtained from any other system.

WASTE-HEAT SAVING

Another distinctive feature of the Koppers' regenerative oven lies in the employment of separate regenerative chambers for all ovens, so that each is entirely independent of its neighbor; this construction permits of the air for combustion and the chimney draught being separately regulated.

A further advantage of the regenerative ovens is that the surplus heat in the coal (i.e., the amount in excess of that required for heating the ovens) is produced wholly in the form of a combustible gas, instead of as a hot waste gas. The combustible gas is of the same character as that produced at gas works, and can be employed for illuminating purposes, and more particularly for consumption in gas engines; in this latter case from two and one-half to three times the power can be generated than when the gas is used in steam boilers. Where power is required in the form of steam, it is generally thought that waste-heat ovens should be adopted, but with that type it is necessary for a special range of boilers to be erected in close proximity to the ovens, while on the other hand, the surplus gas can easily be conveyed almost any distance without loss. It is claimed that the surplus gas from Koppers' regenerative ovens will yield as much steam as the hot waste gas from waste-heat ovens. The coal is conveyed from the hopper to the stamping station and is charged into the oven in the form of a compressed cake.

POPULARITY OF THE KOPPERS' METHOD

The byproduct plant is designed on the Koppers' direct-recovery principle, whereby the ammonia is recovered directly in the form of sulphate, thus dispensing with the usual scrubbing apparatus. Since its introduction about seven years ago, the Koppers' process has met with remarkable success, and there are now installations consuming 25,000,000 tons of coal per annum.

The illustration shown herewith is a diagrammatic representation of the Koppers' direct-recovery system for ammonia. The hot gas from the ovens enters the series of water-coolers of the multi-tubular type, where it is cooled to a normal temperature, thus bringing about the condensation of tar and aqueous vapor. The gas is then drawn by an exhauster and driven forward to a tar extractor, in which the last remaining traces of tar are effectually removed—an operation which cannot be successfully performed without cooling the gases.

After leaving the tar extractor the gas passes through a reheater, and then is delivered direct into the saturator without condensation taking place. The ammonia is extracted from the gas by direct absorption in sulphuric acid, and is recovered in the form of sulphate. The salt is automatically removed from the saturator by means of an ejector working either with steam or compressed air. The sulphate is delivered onto a collecting table and then into a centrifugal dryer, where it is completely freed from mother-liquor.

Saving the Byproducts

The products of condensation extracted in the cooling and tar-eliminating operations are drawn off from the condensers, tar extractors, etc., and conveyed into a separating tank, where the tar and ammoniacal liquor separate, owing to their different densities. The tar flows into one storage tank, and the liquor into another. The liquor is pumped to an ammonia still, where the ammonia is driven off by steam and lime, in the usual way. The vapors of distillation are delivered into the main where they mix with the heated gas, and the whole then passes into the saturator.

No live steam is necessary in the Koppers' process, either for reheating the gas after cooling and tar extracting, or for distilling the ammoniacal liquor. For both these purposes the exhaust steam from the engine driving the exhausters is more than sufficient. No tar is deposited in the saturators, and the salt produced is of the first quality, and is snow white. The gas passes out of the saturator through the main, and is conducted to final coolers, where it is cooled to the required degree for the efficient extraction of the benzol vapor. The benzol is washed out of the gas in the scrubbing apparatus by means of creosote oil in the usual way. After the extraction of the benzol, a portion of the gas is returned to the ovens for heating purposes.

The scrubbing oil containing the benzol in solution, after it has been enriched to the required degree, is delivered to a distilling plant, where the benzol is extracted. The rich oil passes first into a superheater and then into the still proper, where the whole of the benzol contained in the oil is vaporized by means of live steam. The benzol vapor and steam pass through a cooler and condense, the benzol and water formed running into a separator, from which the benzol is run off in the form of a crude spirit.

The debenzolized oil leaves the still at the bottom, and passing through a series of coolers, is cooled down to its original temperature, and again employed for scrubbing the gas. The crude benzol is then washed and redistilled for the production of refined spirit. The whole installation is complete with all the necessary tanks for storing the various products, and with a water-cooling frame, to enable the water employed for cooling purposes to be used over and over again.

The Stonega Plant in Western Virginia

SYNOPSIS—The plant at Stonega is one of the finest in the State of Virginia.

The Stonega colliery of the Stonega Coal & Coke Co. is located about five miles north of Appalachia, in Wise County, Virginia, just across the Cumberland Mountain from Letcher County, Kentucky. The coal mined is the famous Imboden seam, which averages 6 ft. 3 in. in thickness. It makes the best foundry coke on the market and is also a good domestic coal. There are four mines at Stonega which are all self-draining and free of gas. In three of the mines the coal is mined by hand, machines being used in the other. The coal is hauled by electric motors, and ventilation is provided by two Capell fans

There are 666 beehive coke ovens, 200 of which are equipped with a Covington coke-drawing and loading machine. A modern coke-crushing plant prepares the coke for domestic use.

Two of the three large tipples at Stonega supply the coke ovens, and are equipped with Stedman disintegra-

Arched Opening to No. 3 Mine. The Arch Is only 12 In. Thick

Inside of Machine Shop of Stonega Coal and Coke Co. and Interstate R.R.

tors. The third tipple ships coal, and coals engines for the Interstate R.R. The plant of the latter tipple has a large brick power house with stone foundation and trimmings which contain three 500-volt direct-current generators, which furnish power for the mines and one machine also supplying direct current, which furnishes energy for use in lighting the streets, dwellings and office buildings.

PLANT NO. 1 OF THE STONEGA COAL & COKE CO., STONEGA, VA. COKE CRUSHER ON LEFT, POWER HOUSE IN MIDDLE FOREGROUND AND TIPPLE ON RIGHT

To supply steam for these units is a boiler house containing a battery of ten Brownlow boilers.

ALL KINDS OF REPAIRS ARE MADE IN THE REPAIR SHOP

A large machine shop equipped with lathes, shapers, planers, wheel-press, radial drill, bolt-and-pipe machine, shears, punch and steam hammer makes all repairs around the plant and also does all the work of that character needed by the Interstate R.R., which terminates at Stonega. At another repair shop all electrical repairs are made, armatures being wound and commutators built by the force engaged. At a large foundry castings up to 2000 lb. are made at this plant.

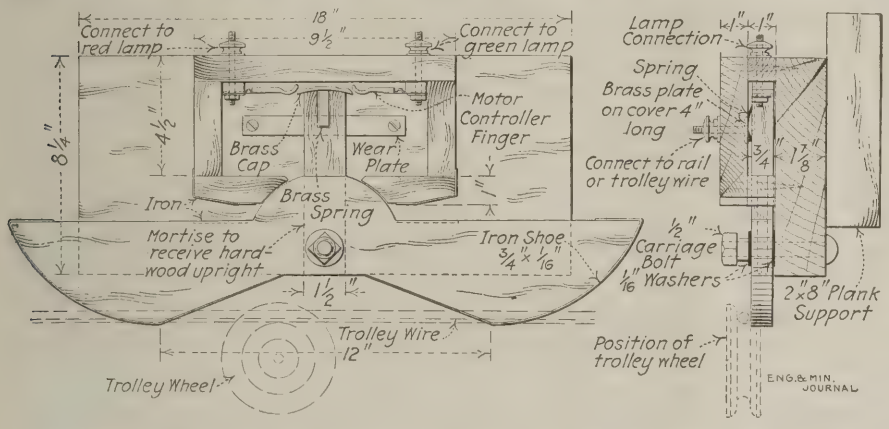
At Stonega, there are Presbyterian, Methodist-Baptist Union and a Catholic Church, and for colored people only, Methodist and Baptist Churches. A four-room graded school for white children and a two-room school for colored children supply the educational needs. For amusement a picture theater and lodge hall is provided. Pictures are run nightly, admission to the entertainment being obtained for 5 and 10c. There is a good library and a pool room, which was donated and is maintained by the company.

The corporation also has for the population of about 2000, a fine hospital in charge of Dr. C. B. Boyer, the company's physician, who is aided by two trained nurses.

The Stonega plant is in charge of C. G. Duffy, superintendent, and his assistant, H. B. Price, Jr. It is one of six plants located within a radius of seven miles. The headquarters of the Stonega Coal & Coke Co. is located at Big Stone Gap, Va.

THE STONEGA BASE BALL TEAM OF 1912

Automatic Light Switch Signal



BY L. O. KELLOGG

It frequently happens in underground electric-haulage systems that the main drift branches a short distance from the shaft and that loaded trains are brought in over both branches. It then becomes necessary to signal to any incoming trains whether the track between the junction and the shaft is open or whether a train from the other branch drift is dumping at the pocket. This signaling is done automatically by colored lights in an exceedingly neat way at the Oliver mines near Ely, Minn. A switch is set in the back of the drift so as to be tripped by the trolley wheel of the incoming train and to flash a red light. The trolley wheel of the outgoing train usually flashes a green light. A train approaching on the other branch drift will stop if the motorman sees a red light and will proceed if he sees a green.

It is not entirely necessary to use the green light, but somewhat safer; for if two lights are used, the absence of

either a green or a red light indicates that something is wrong with the system, and the motorman will not proceed as he would if the mere absence of a red light was used to indicate a clear track. Only one switch is necessary, set where it will be operated by trains from both drifts. One or two sets of lights may be used, only one set being required, if a point can be had visible from a sufficient distance in both drifts.

The construction of the switch is shown in the drawing. It consists of a wooden box inclosing the contacts. A vertical pivoted finger is connected through the bottom of the box with two horizontal wings which the trolley wheels strike; the finger, thrown laterally by the movement of the wings, completes a circuit through the lamp of the proper color. The wings of wood are shod with iron where struck by the wheel and where they

Automatic Switch to Indicate Position of Underground Motor

strike the bottom of the box, in order to resist wear. The top of the wingpiece is shaped as an arc to fit the opening in the box, which is thus kept closed. The box itself consists of a wooden back and a wooden front piece screwed together through filling blocks which form the box sides. The finger, by means of the brass spring shown, maintains a constant contact with a brass plate on the inside of the box front piece, which is connected to one side of both lamp circuits. The spring connects with a brass cap on the finger, and this makes contact with one of two fingers taken from a motor controller. One of these connects with the other side of the red-light circuit, the other with the other side of the green light. In the case shown, the trolley current is used for the lights; if a separate lighting circuit were in service, connections could be as easily made to this. The device is mounted on a board parallel with the tracks.—*Eng. & Min. Jl.*

Safe Boiler Support

The importance of safe boiler support is not generally recognized, says an editorial in *Power* for Mar. 3, 1914, and the boiler laws that have been enacted in the various states and municipalities, do not seem to have taken into account its influence as affecting the safe operation of boilers. Anyone familiar with boiler explosions will be sure to feel that if a boiler should fall down while under steam, an explosion would be almost certain to follow; yet it is rare to hear this cause advanced as the explanation of boiler explosions where other causes are not in evidence. It seems more than probable that a good number of mysterious boiler explosions, occurring with sound boilers and where there has been conclusive evidence that no overpressure existed, may have been due to the falling down of the boilers or their changing position to such an extent as to result in the breaking of the pipe connections, thus producing the explosion.

Investigation into the conditions surrounding the explosion of two sound boilers recently, seemed to indicate that the falling down of one of the boilers was the only reasonable explanation for the accident. These two boilers exploded simultaneously, the explosion of one having undoubtedly been the cause of the explosion of its mate. The tears through the shells of both boilers were similar, occurring through the top manhole reinforcement, which was of the outside pattern, and weak. The girth rivets at each end of the course that contains the manhole opening were sheared. All parts of the shell that were fractured were without evidences of defects, the tears being through the solid plate. Calculation showed that the structure should have stood about five times the load due to the steam pressure that was on the boilers at the time of the accident, and that there was not an excess pressure at this time was clearly indicated by the condition of the pop safety valves that were attached to the boilers. One boiler showed distinct marks on the manhole course of having been dented by a blow delivered to it by the manhole frame of the adjoining boiler when it exploded. From the nature of the breaks on these boilers, it is probable that the main steam connection on one boiler was broken by the falling down or settling of the boiler. The sudden opening and the resulting outrush of steam, caused a wave action of the water in the boiler, which resulted in its rupture girthwise and the manhole course lengthwise through the manhole reinforcement. This explosion probably would have been prevented if the boilers had been properly hung.

The Massachusetts and Ohio rules prescribe that boilers above 78 in. diameter be hung, and that the support be independent of the setting walls. This provision was evidently made for fear that such large boilers could not be safely supported on the setting walls, which is doubtless correct. It would also seem to be reasonable precaution to have all sizes of horizontal tubular boilers hung. The smaller size boilers are usually installed in the smaller plants where the condition of the setting is not as apt to be so closely watched as in the larger plants and small boilers for this reason are probably more likely to be exposed to the danger of explosion from improper support.

The American Boiler Manufacturers' Association, at its twenty-fifth convention, proposed that the Massachusetts Rules be modified in regard to the requirements for hanging boilers and that the boiler manufacturers be allowed to follow the present practice, which had been proved safe. Such a move would seem to be a step backward, and if any change is made it should be to require that the smaller sizes of boilers also be hung. It requires more than the mere statement of the boiler manufacturers to show that lug-supported boilers are safe, for there have been many instances to show that this means of support has often been the initial cause of boiler explosions.

King Coal

By Robert H. Wilson*

A coal fire burns on my hearth tonight,
Outside is the frost and snow,
The stars are a-shiver with cold and fright
As they hear the north wind blow.

Jack Frost peers in at the casement frame
With a leering, bold grimace;
The fire cries out, "You're not in the game,"
And it flouts him to his face.

The Frost King mutters, and in his voice
Is a tone of gruff regret,
The coal laughs back, "You have no choice,
For I am the master yet!"

"If thou art King," said I to the coal,
"Tell me thy warrant, pray,
That aught to thy power should yield control,
Or bend to thy scepter's sway."

"And thou wouldst know," said the coal to me,
"My secret, then listen well,
For it is a tale of mystery,
And wonder I have to tell.

"I was conceived of the virgin Earth
When time had only begun,
Forests and jungles my place of birth,
'Neath the shine of a tropic sun.

"My cradle was down in a swampy fen,
Where the ichthyosaurus fed,
The diplodoccus came from his den,
And guarded my trundle bed.

"Surges and billows, and roll on roll
Of shimmering light and heat
Wrapped me and filled me, body and soul,
Till my pulses wildly beat.

"I breathed the heat, and I drank the light
Till the glacial torrent's spume
Flooded and buried me out of sight,
Again in my mother's womb.

"Reincarnation! Wonderful theme!
But the marvel came to me
Of birth anew, like the mystic dream
Of the Brahminic devotee.

"Ho! for the craft of the sons of men,
Ho! for their cunning and skill,
Delving for treasures beyond their ken,
And molding them to their will.

"They searched me out from my dark, damp caves,
Braving my poisonous breath,
They brought me from 'neath the salt sea waves,
At risk of the fangs of Death.

"They gave me a kingdom, a crown, a throne,
And millions before me fall,
Trade and traffic my empire own,
And industry is my thrall.

"My hand directs the billowy course
Of the ocean-greyhound fleet,
My blood is life to the iron horse,
And strength for his flying feet.

"At touch of my magic—commerce feels
The spur of a thousand thrills,
I drive the shuttles, and turn the wheels
In thousands of shops and mills.

"I yield my life—though I reckon it not—
To defeat the demon Cold,
I quicken the fires in the smelting pot,
To purge the silver and gold.

"I warm the home of the millionaire,
And the hut of the Esquimaux;
Eyes dreamy with youth find pictures rare
In the depth of my ruddy glow."

* * *

"King Coal is a Suzerain Lord," I cried,
"With power on land and sea,
I yield him due homage, whatever betide,
For he warmeth my hearth and me."

*Saltsburg, Penn.

Increase in Baltimore Harbor Facilities

The rivers and harbors appropriation bill, pending in Congress, is of wide significance to the coal trade of Baltimore. The bill contains a provision for the expending of $112,000 by the government in deepening the Baltimore harbor to 35 ft., making it possible for the largest merchant vessels and colliers of the United States Navy to load coal at the Maryland port.

In discussing the proposed legislation with Congressmen Linthicum and Talbott, of the Maryland delegation, President Daniel Willard stated that the Baltimore & Ohio will build an additional steel pier at Curtis Bay, which will double the capacity of the present facilities there. The time of construction, the cost of which will be more than $1,000,000, will be dependent upon the financial condition of the road. It is known, however, that the pier will be erected as soon as practicable.

Eastern coal operators, and particularly those doing business through this port, predict a rapid growth of the trade when the proposed extension shall have been put in operation. Baltimore is a logical point for handling a large volume of coal. It is also located near the coal fields of West Virginia, southwestern Pennsylvania and Maryland; and now that a low-grade route has been established, which makes it possible to handle the longest trains expeditiously and economically, a large increase in tonnage is anticipated.

Last year more than 3,000,000 tons of coal were dumped over the Curtis Bay pier, and the world's record for loading a vessel was established on Nov. 18, 1912, when the collier "Newton" was loaded with 7473 tons of coal in 3 hr. and 45 minutes.

Dwelling Houses at the L. C. & N. Co.'s New Hauto Plant

By Edward L. Kellogg*

SYNOPSIS—The gradual leaning toward better construction of workingmen's quarters is becoming more noticeable each year. It is generally conceded that comfortable houses do much to attract and hold a more desirable class of men. This article describes the introduction of hollow-tile at the L. C. & N. Co.'s Hauto plant and is probably the first application of this method in a mining community.

It is so short a time since the building of modern model villages in America for workingmen has been gaining ground, that the broad principles which underlie such expenditure on the part of a corporation for such a purpose need stating and reiteration. The increasing difficulty of obtaining satisfactory help for industrial

Front View of the Two-Story House

plants is compelling managers to analyze among other things the living conditions of their men, and they find that high-grade workmen of today are not content with wooden shacks in the middle of bare ground covered with refuse, cans and ashes; and will not stay in towns where housing conditions are poor.

There is, as is well known, a large floating class of workmen who only stay a short time in each place, leaving under the slightest pretense. The scarcity of labor has made reliable men more particular and most of these prefer to work for lower wages in towns where they can get better and more attractive homes.

Some Advantages of Improved Dwellings

It has long been noted that under average conditions the loss of time from sickness has been 10 per cent., but in model villages is almost nothing, while the death rate is one-quarter to one-half what it is under ordinary conditions. It is easy, therefore, to realize that the better physical, mental and moral conditions of the men make them more efficient workmen.

From the increased efficiency, additional profits come to the employer sometimes in so large amount that the management feels justified in maintaining a model village at considerable actual expense. Others place rentals at a markedly lower figure than would be justified, if an ordinary real-estate investment proposition. The accompanying table, prepared as a rough guide, has been so frequently called for by managers of large corporations, that it will no doubt be welcomed by others. The cost of land mentioned pertains specially to country districts where land is cheap.

SCHEDULE OF COST AND RENTALS OF HOUSES FOR WORKINGMEN

Cost of House	No. of Rooms	Interest at 5%	Annual Total Expense	Rent per Month	Rent per Year	Annual Surplus % Income
			Sink and Toilet			
$750	3	$37.50	$65.10	$6.00	$72.00	10
860	3	43.00	74.80	7.00	84.00	11
975	3	48.75	84.80	8.00	96.00	12
1100	4	55.00	95.40	9.00	108.00	12
1200	4	60.00	104.50	10.00	120.00	13
1300	4	65.00	112.80	10.50	126.00	10
1400	4	70.00	121.10	11.00	132.00	9
			Bath, Sink and Toilet			
1500	5	75.00	130.40	12.00	144.00	9
1600	5	80.00	139.30	13.00	156.00	10
1725	5	86.25	149.10	13.50	162.00	8
1825	5	91.25	157.40	14.00	168.00	6
1925	5	96.25	167.50	15.00	180.00	7
2025	5	101.25	174.80	15.50	186.00	6
2150	6	106.25	183.35	16.00	192.00	4
2250	6	111.25	191.75	16.50	198.00	3
2350	6	116.25	199.95	17.00	204.00	2
2475	6	123.75	211.30	18.00	216.00	3
2575	6	128.75	220.90	19.00	228.00	3

Taxes are figured at the usual 1 per cent of cost of house and land. Repairs are figured at cost of one month's rent, standard practice for even less durable construction than hollow tile.

Collection expenses at 5 per cent. of rent collected.

Sinking fund at 1½ per cent. of cost of house only. At 5 per cent. compound interest a 1½ per cent. sinking fund will repay cost of house in thirty years.

In many of the coal-mining towns, the housing of miners is poor and commonplace, due to several reasons:

(1) The lack of interest of the actual operators of the mines, and the absenteeism of the responsible heads and owners of the companies, and

(2) The feeling on the part of the managers that the perhaps early exhaustion of the coal seams will bring an end to the value of real property.

A leading executive recently said to me: "Our company has over one hundred houses in this town that should not be occupied by human beings. I am constantly asking for new houses, as they pay a fair interest on the investment, but my directors will not authorize the expenditure."

Reasons for Adopting Permanent Construction at Hauto

Vice-President Ludlow, of the Lehigh Coal & Navigation Co., with headquarters at Lansford, Penn., takes great interest in his company's employees. His company's experience with wooden houses and the heavy repairs necessary on them, has led him to investigate other more durable methods of construction. The thick veins of coal belonging to this company promise work for scores of years, so that more durable construction than wood was economically important.

The building of the great electric plant at Hauto, near Lansford, to use up the long accumulating millions of

*Standard Buildings, Inc., 70 East 45th St., New York.

tons of waste coal in generating electricity on an enormous scale for surrounding towns and cities, gave Mr. Ludlow an opportunity to carry out his idea of a model village for the employees of the plant.

Standard Buildings (Inc.), of New York, an association of experts on the laying out, designing and erecting of model villages for workingmen, was asked to do the work. This company makes a specialty of building with hollow tile, and in the effort to reduce the cost so as to compete with good wood construction, had devised in coöperation with the National Fireproofing Co., a new hollow tile with a pleasing exterior surface, warm red in color, something like tapestry brick, at one-third the cost, thus doing away with the expensive exterior stucco. The unit of tile, 6x12-in. face by 6 in. thick, with double air spaces, will, where properly laid with portland cement, make an impervious masonry wall, warm in winter and cool in summer.

A number of houses illustrated herewith have just been finished. The appropriation available called for the strictest economy; all architectual features had to be omitted, but the result is nevertheless most interesting. The delightful warm, red brick color of the roughened wall surface, and the size of the units with the wide grey mortar joints, make a pleasing exterior. The roofs are of heavy durable prepared roofing, matching the walls in color, and put on with heavy battens painted the same color. The exposed woodwork is stained a warm brown and the window sashes painted cream white.

Rear View of the Two-Story House on the Left and the Bungalow Type on the Right

Types of Buildings Used

Three types of houses have been erected, as illustrated:

(1) *Bungalows* containing a large living room, two double bedrooms, of over 800 cu.ft. of air capacity each, and a kitchen. There is a center chimney, a water closet, a soapstone washtub and sink. The cooking range will heat the house from the living room in winter and in summer can be moved into the kitchen. There is a large front porch and a smaller one in the rear. The hollow tile in these bungalows is smooth on the interior and is white-washed, doing away with the use of plaster and presenting a most durable surface practically proof against wear and tear.

(2) *Five-Room, Two-Story Houses.* The rooms in the second story are full height. There is a living room, dining room, kitchen, two bedrooms and bath. Also a cemented cellar and excellent hot-air furnace.

(3) *Six-Room Houses*, similar to those with four rooms, but with a larger living room and three bedrooms. Good closets are provided in all these houses. The five- and six-room houses are plastered in the usual way with white, hard finish for painting or tinting.

The illustrations taken in mid-winter, with the streets dug up for water pipes, give little of the real beauty that will be apparent later when a year or so has passed, and nature has again taken hold, the grass grown and the leaves out, and human interest apparent and active. But this experiment has already shown that given an interesting and durable material, and skilled design limited, to proportions alone, will together make a beautiful whole. The credit for part of the idea of the new wall material for low-cost houses, should be given to that eminent business man and philanthropist, J. G. Schmidlap, of Cincinnati, who has invested half a million dollars in two housing companies in his own city. His remark to the president of Standard Buildings, Inc., a year ago: "You will not be able to lower the cost of workingmen's houses until you find some cheaper structural material," led to the experiments that finally produced the new hollow tile, whose first use is illustrated herewith.

The Scottish Coal Ports

The North British Railway Co. has been interested in the export of coal from the rich Fifeshire fields, almost since the beginning of coal mining. From a charter dated March, 1291, it appears that coal has been worked in that county for more than six centuries. Many of the Fifeshire seams extend for considerable distances under the Firth of Forth, and it is estimated that the quantity of coal still to be worked is 3,742,336,644 tons, according to a Royal Commission, which sat in 1903-5. The total output of the county in 1907 was 8,530,043 tons, as compared with only 5,944,631 two decades ago.

Soon after the acquisition of the original dock at Methil by the North British Railway, in 1889, the traffic of the port increased to such an extent that it was found necessary to extend the facilities for handling coal. The construction of the outer dock, which has an area of 6½ acres, was completed in January, 1900. The dock has a depth of water at high tide of 27 ft., and 22 ft. at low; its cost was about $1,500,000.

The coaling facilities consist of three Armstrong Whitworth coal hoists of the most approved types with high-level runways for the empty wagons. There is also a 25-ton hydraulic coaling crane, which can lift the loaded

wagon bodily and empty it direct into vessels, and also work alongside one of the coal hoists so that a vessel can be loaded by both methods simultaneously.

There are 12 miles of storage sidings round the docks and the whole are lighted by electricity to facilitate work at night. With all the hoists working there is no difficulty in handling 70,000 tons a week and a record shipment for one week was accomplished on July 8, 1911, when 75,595 tons were shipped; the record monthly shipment was made in September, 1911, when 311,883 tons were handled.

The total tonnage shipped from the Methill Docks during 1909, was 2,691,109 and in 1910 it was 2,926,210 tons. The traffic at Methil has again outgrown the facilities and a third dock is nearing completion, which has a water area of 16¼ acres and will be equipped with six additional miles of sidings. The hydraulic hoists will be capable of lifting a weight of 35 tons to a height of 45 ft., above the quay level and tipping into vessels. When this dock is completed the loading capacity of the port will be increased to 160,000 tons per week.

General View of the Burntisland Dock in Scotland

Other Large Docks

The other important outlet of the Fifeshire coal field is Burntisland, where the docks are also the property of the North British Ry. Co. In 1889 the coal tonnage shipped from this port was only 739,307, while in 1908 it was 2,164,293 tons, and in 1910 it was 1,128,218 tons.

There are two docks, the old and the new, the former having a depth of 28¼ ft., and the latter 22½ ft. Both docks are fully equipped with the latest coaling appliances and there are no fewer than ten hydraulic hoists, which are said to be the first of their kind erected in Scotland, while experiments have been made with antibreakage appliances with satisfactory results. The record shipment of coal for a week was that for Aug. 7., 1909, when 68,100 tons were shipped, and the record month was October, 1908, when 256,000 tons were put into vessels.

Automatic Stone Dusting

H. W. G. Halbaum, in a paper before the North of England Institute of Mining Engineers, offers some interesting notes on stone dusting. Instead of employing a number of men to clean up the coal dust and distribute the stone dust every night, he suggests that the inert dust be stored at the surface in such a way that it will be subjected to the suction of the downcast shaft (as coal dust now is from the screens). Secondly that another supply of inert dust should be taken nightly to the haulage landing of each district.

During working hours the cager is provided with a number of shallow trays made of galvanized sheet iron, and fitting the tops of the full cars. In each of these trays he places a few handfuls of the inert dust. The tray would prevent the coal dust from escaping from the cars, while the inert dust reposing in the tray would be shaken up as it traveled, and carried away and deposited by the air current. This would obviate the cleaning-up of the haulageways each night, since the deposition of coal dust would be prevented, and the roads would be efficiently stone-dusted.

This seems to Mr. Halbaum the logical conclusion to the study of the distribution of dust, whether it be formed from coal or stone. Such a method would have the twofold effect of practically preventing the deposition of coal dust on the main haulageway and covering instead its whole rubbing surface with fine inert dust. If the buoyancy of the inert dust be sufficiently marked, it should penetrate into obscure parts of the mine, which have hitherto been accessible only to coal dust.

Mine of Birmingham Fuel Co. at Townley, Ala.

EDITORIAL CORRESPONDENCE

SYNOPSIS—A description of the Townley Mine; its location, equipment, working methods and output.

The mine of the Birmingham Fuel Co. is located geographically at Townley, Walker County, Ala., on the St. Louis and San Francisco R.R., 52 miles northwest of Birmingham, and geologically in the northwest corner of the Warrior coal field. The mine is under the general supervision of John R. Pill, president and general manager, and under the direct supervision of John B. Monfroy, superintendent. The writer is indebted to the two gentlemen mentioned for their coöperation in preparation of this article.

FIG. 1. GENERAL VIEW OF PLANT

A, dwellings; B, office; C, commissary; D, washer; E, bath house

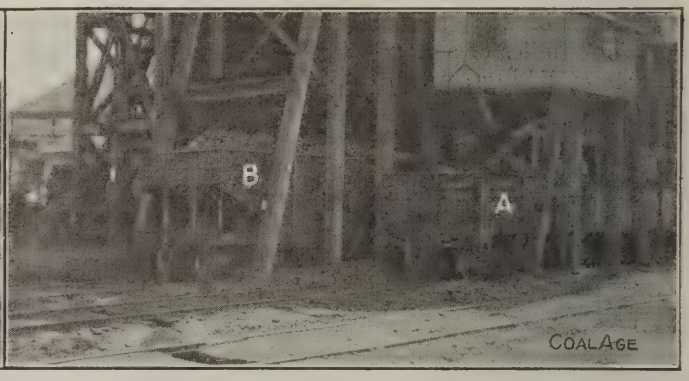


FIG. 2. METHOD OF LOADING

A, domestic lump over 6-in. screen; B, steam through 6-in. screen.

The Jagger Seam, which is worked in this mine, is one of the lowest seams of the Warrior field and is of workable thickness only in the northwest corner of the field. The coal occurs in irregularly shaped basins, the limits of which can only be ascertained by drilling. Normally, the coal lies flat with local variations and, as a rule, it is of normal thickness, except near the boundary of a basin, where it thins rapidly and turns up to the surface. It is impossible to ascertain the limit of a basin by cutting the outcrop, as the seam on "turning up" usually plays out. The approximate boundary of a basin is shown usually by the appearance of the bed rock on the surface.

The roof of the seam consists of shale of average strength and the floor of firmer shale. At some points of the field a stratum of bone coal, 6 in. to 8 in. in thickness, occurs in the bottom.

The coal is an excellent domestic and steam coal and finds a ready market. The steam sizes bring from $1.20 to $1.50 per ton, and the lump from $1.75 to $2.25 per ton, f.o.b. mine, the prices varying with the seasons. Fig. 2 shows two grades being loaded, lump and steam, while Fig. 6 is a photograph of a car of fancy lump over 6-in. shaking screen.

Figs. 1, 3 and 4, which are photographs of the plant from different points of vantage, show the general arrangement of the buildings. The reader's attention is particularly directed for a moment to the general neatness evidenced by the photographs. It might be mentioned in this connection that "good order" is characteristic of the plant both on the surface and inside of the mine.

The boiler plant consists of four 165-hp. Atlas return-tubular boilers. The boilers are equipped with four 16-in. turbo-blowers. The water is fed from a 500-hp. Star

FIG. 3. VIEW OF PLANT FROM RAILROAD SIDE

A, headframe; B, hoist-engine room; C, compressor room; D, drinking fountain; E, bath house; F, carpenter shop; G, machine shop; H, blacksmith shop.

vacuum heater which is on the exhaust from the air compressors. An important economy is effected in the boiler plant in that only the washed slack which passes through a ⅜-in. screen is used in firing, except when this supply is insufficient, at which times quantities of the larger sizes are used. This method utilizes principally the fine product, which is of the lowest market value. All boiler coal is delivered to the boilers from the washers by flume *g*, shown in Fig. 4. Flume *h* disposes of the extreme fines from the boiler coal.

The power plant consists of three Norwalk compressors, each having a capacity of 900 cu.ft. per min., which supply compressed air for the coal punchers and pumps; and a Janney direct-current generator, which furnishes lights for the principal buildings and the shaft bottom.

The headframe is arranged for self-dumping cages, which dump directly into the shaking-screen bin. The cages are operated in balance by a first-motion Crawford & McCrimmon hoisting engine.

The fan, shown at *d* in Fig. 4, is a 16-ft. Crawford & McCrimmon fan. The fan house is of the Kahn system of reinforced-concrete construction, and is arranged so that the direction of ventilating current can be reversed. It is also equipped with explosion doors.

The washer, a two-jig Montgomery type, washes everything from 3 in. down. The raw coal is separated before being washed, and all coal passing through a 1½-in. revolving screen is washed in one jig and larger sizes in the other jig. Chutes and conveyors are so arranged that the entire washed product, or the sizes above 1½ in., can be put in with the nut coal or loaded separately to suit the demand. All coal that is not washed is hand picked. (See Fig. 2.)

The washer refuse is very economically disposed of at this plant. It is hauled from washer to dump over the track shown at *l*, Fig. 4, by means of a tail-rope which winds on a drum equipped with friction on the driving shaft of the jigs. The rope can be seen in the photograph. The refuse car automatically dumps at the proper place.

There are two features of the surface plant that are not in the strict sense of the word necessities for a coal mine, but are the ear-marks of an operator that has the best interest of the mines at heart, they are: The drinking fountain, shown at *d*, and the bath house, shown at *e* in Fig. 3. The fountain is fed, by means of a compressed-air line, from a stream that was struck in the main shaft. The fountain is of concrete construction. The bath house is not yet in use, but is nearing completion. It is also of concrete construction, and when completed will be equipped with sufficient showers and steel lockers to accommodate the workmen. In keeping with modern practice, the name of each building is plainly painted thereon.

The main, or hoist, shaft is 10x20 ft., 126 ft. deep, with three compartments, two for hoisting and one for

FIG. 4. VIEW OF PLANT FROM MUCK DUMP

A, washer; B, headframe; C, boilers; D, fan; E, machine shop; F, carpenters' shop; G, flume for boiler coal; H, flume for wasting extreme fines from boiler coal; I, track for washer-refuse car.

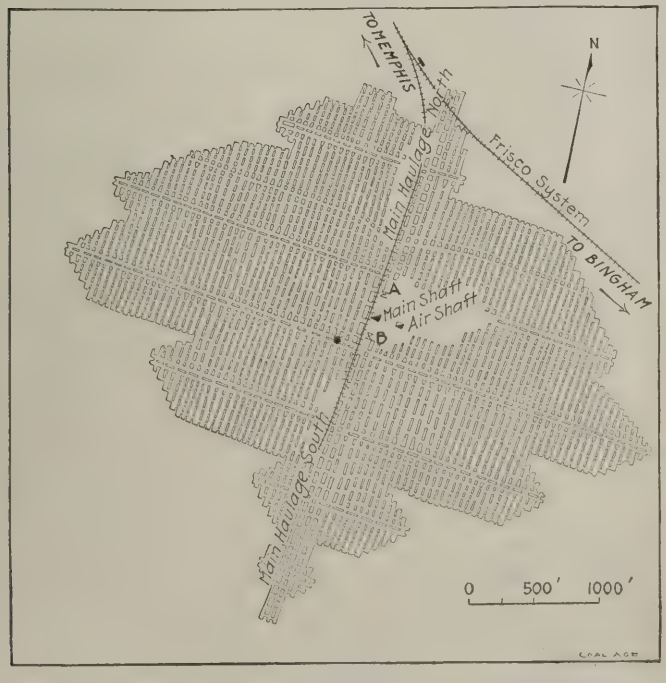

FIG. 5. UNDERGROUND PLAN OF BIRMINGHAM FUEL CO.'S TOWNLEY MINE

FIG. 6. CAR LOADED WITH FANCY LUMP PASSED OVER A 6-IN. SHAKING SCREEN

pipes, etc. The timbering is of pine. The air, or fan, shaft is 100 ft. east of the hoist shaft. It is 10x14 ft., with two compartments, separated by a reinforced-concrete wall. One compartment is connected with the fan and the other used for a manway. The manway compartment is provided with a steel ladder built in short flights. It is used in emergencies only, as the men are let into and out of the mine by means of the cage.

For the protection of life and limb, and for the sake of general neatness, all timbers and ribs of main headings adjacent to the main shaft, as well as those of passages to the manway, are kept well whitewashed.

For the protection of the shaft and surface plant, a 60-ft. pillar was left between the main haulageway and air courses on both sides of the shaft to the first headings. Sufficient pillar was also left around the airshaft for its protection. The reader will note, upon reference to Fig. 5 that main haulageways are driven north and south from the shaft. These haulageways divide the basin, as nearly as possible, into equal parts. They are driven 18 ft. wide with a 15-ft. air course on both sides, and a 20-ft. air-course pillar.

From these main entries, at intervals of 400 ft., double entries are turned at right angles. The double entries are driven 13 ft. wide with a 20-ft. pillar between. These double entries, as well as the main entries, are driven on sights. Rooms are turned from the double entries on 35-ft. centers, and the coal mined by the room-and-pillar-advancing method, with 25-ft. rooms and 10-ft. pillars. The rooms are necked off 8 ft. wide at the heading and substantial stumps are left alongside the heading. Such pillars as it is possible to rob are robbed on the retreat.

In mining, the coal is undercut with Ingersoll-Sergeant coal punchers and shot down with black powder. In

CAMERON COLLIERY OF MINERAL RAILROAD

shooting, the holes are drilled up through the shale parting near the top, and the powder bedded in and above the parting. Charges strong enough to break the coal down, but not to scatter it, are used. In this way it is possible in loading the coal to uncover the parting and throw a large part of it into the gob, without it becoming mixed with the main body of loose coal, and, at the same time, correct shooting yields a larger percentage of lump coal. In this mine the average yield per keg of powder is 90 tons, which represents an actual shooting charge closely approximating 2c. per ton.

The ventilation is a combination of the split and continuous systems. The mine is divided into four quarters by the ventilation scheme, and each quarter, or corner, is ventilated by a separate split of air, which passes, without further splitting, through the workings. This system gives each section of the mine a sufficient supply of fresh air and necessitates only two overcasts. These overcasts will be noted on Fig. 5, on the main haulageways on either side of the hoist shaft at points *A* and *B*. In order to prevent the main shaft from freezing, the fan is used as a blower during the severe winter months.

The mine does not make any considerable amount of water; therefore the pumping problem is comparatively simple. Three pumps are maintained which have a combined capacity far in excess of the demands. They are all Camerons—one No. 10A, one No. 8 and one No. 3.

The mine has an average daily output of 1200 tons, which is undercut with 16 punchers and hauled by 26 mules. The high yield per mule is made possible by the excellent condition of the tracks. The mules are stabled outside and are taken into the mine on the cages.

The mine employs a total of 315 men, 24 of whom are used outside and 291 inside.

AND MINING COMPANY, SHAMOKIN, PENN.

Anthracite Coal and the Public

The *Philadelphia Public Ledger* of Mar. 20 prints the following editorial under the title, "An Invisible Hand Takes Heavy Toll on Anthracite:"

Nothing but a long and tedious lawsuit can decide whether the Lehigh Valley maintains a coal trust. But no trial is necessary to convince all consumers of anthracite that they pay too much for it.

The United States census figures of 1910 showed that the average value of a ton of anthracite loaded on cars at the mines was $1.86. That the price included the royalty paid by the operators to the owners of the coal.

To bring a ton of anthracite from the mines to Philadelphia costs from $1.70 to $2 a ton. It is true that the census figures for the value of a ton of mined coal did not include interest on the enormous sums invested in the properties.

After allowing for a substantial rate of interest and after establishing a sinking fund for the exhaustion of the mines, the difference between that and the more than $7 which the consumer pays is entirely too much.

Somewhere an invisible hand appears to reach out and collect a heavy toll on every ton of anthracite between the time it leaves the mine and the hour it is put into your cellar. Whose hand is it? To whom does that toll go?

This we do know, that of all the railroads in America the anthracite companies as a group are much the most prosperous. Lackawanna's 20 per cent. dividend, Jersey Central's 12, Lehigh Valley's 10, Delaware & Hudson's 10, and Reading's 8, show that these carriers thrive no matter how hard other roads struggle to make both ends meet.

Perhaps those invisible hands which collect the heavy tolls on anthracite belong to the coal sales companies, for they also thrive mightily and pay big dividends on a capital stock distributed free to the shareholders of at least two coal railroads.

In answer to the above statements, Eli Conner, of Philadelphia, makes the following reply:

Mar. 20, 1914.

Editor "Philadelphia Ledger,"
Philadelphia, Penn.:

Dear Sir—Noting your editorial in this morning's "Ledger" entitled "An Invisible Hand Takes Heavy Toll on Anthracite," I desire to call your attention to the unfairness of some of your statements.

I hold no brief from any of the anthracite corporations, but 20 years' experience in a managerial capacity, besides frequent professional engagements in that region, gives me intimate knowledge of the conditions governing the industry. I believe the "Ledger" is fair enough to justly present the situation to its readers.

The cost of producing anthracite coal and the prices realized by the mining companies therefor, was exhaustively set forth in House of Representatives Document No. 1442, 62d Congress, entitled, "Increase in Prices of Anthracite Coal Following the Wage Agreement of May 20, 1912." A statement is given in this document showing "operating cost per ton of 2240 lb. at collieries, not including royalties, taxes, sinking fund, interest on investments, or general office expenses," of seven of the largest producing corporations, whose aggregate output in 1911 was 35,382,545 tons, or about 52 per cent. of the total output of the whole anthracite region. The average cost of producing this large amount of coal on the above basis was, in 1911, $1.897 per ton. The wage increase of 1912 was computed at an average for the whole region of about 9c. per ton, which, added to the 1911 average, brings the cost up to $1.987.

The items excluded from the statement above quoted, namely royalties, taxes and sinking fund, but omitting interest on investments, would throughout the region average at least 25c. per gross ton, bringing the cost up to $2.337 per ton at the mines, or 0.477c. per ton more than the cost figure quoted in your editorial, $1.86.

The tendency in the production of anthracite coal is toward constantly increased costs, due to the general increasing "cost of living"; to the greater amount of coal that must be won from thin beds, which in order to be mined at all necessitate the removal of large quantities of rock to make working height; to the greater depths and longer distances the raw product must be transported underground; and to the fact that to properly conserve the mineral, it is necessary to mine as they are encountered in downward development, thin and lean beds at an actual loss, or else leave them in such a state that by reason of extracting beds beneath them they cannot hereafter be recovered; in other words, destroy them for all time.

Therefore, it is probable that the general average cost of producing anthracite coal at the present time is above the figure quoted, $2.337. There are, to be sure, companies whose mines are exceptionally favored by natural conditions, resulting in lower costs than this, but a general average is a fair one.

Now as to the other statement contained in your editorial, the price charged the consumer, over $7 per ton. You do not qualify this statement, merely comparing it with the quoted cost of $1.86. This is quite misleading. While it is true that the sizes of coal known as domestic sizes, namely, broken, egg, stove and chestnut, are retailed at the quoted figure above, these sizes constitute but about 60 per cent. of the output. In other words, to produce an average ton of anthracite, 40 per cent. is in the so called steam sizes, known in the trade as pea, buckwheat No. 1, No. 2 and No. 3, mustard seed and screenings, which sizes are all, with the possible exception of pea, byproducts of the industry, and must be sold in competition with bituminous coal.

The price realized by the anthracite-mining companies is, therefore, the average of all the sizes sold. On the basis of 60 per cent. domestic sizes and 40 per cent. steam sizes, and at the market prices prevailing in 1913, after deducting selling expenses, the average price realized by the producers of the whole anthracite region "at the mines" would not exceed $2.85 per gross ton.

The question of the freight rate for transporting anthracite coal to market is another matter that will doubless be solved in due time, but the fact should not be lost sight of that there are many mines now being operated at an actual loss, which loss is partly recouped from the freight profit. If this latter is greatly reduced, the unprofitable mines must necessarily be abandoned. The remaining mines will then be unable to supply the demand for anthracite coal, and as a natural consequence the price will go still higher, and the last state of the consumer will then be worse than the former.

ELI T. CONNER,
Mining Engineer.

Stephen-Girard Building, Philadelphia, Penn.

Explosives in Coal Mines Order

Secretary of State R. McKenna recently issued an amending Explosives in Coal Mines Order, under date of Feb. 10, 1914, in pursuance of the power conferred by Sec. 61, of the Coal Mines Act, 1911. By this order, the explosive "Bellite No. 4," of the order of Sept. 1, 1913, is withdrawn from the schedule, another "Bellite No. 4" being substituted therefor. Also, the explosive "Sheppey powder" of the Order of Nov. 25, 1913, is withdrawn from the schedule.

The Order of Feb. 10, 1914, adds six new explosives to the permitted list of the previous schedules. The added explosives, which have passed the new Rotherham test, for Canada, are as follows:

Bellite No. 4—Composition (parts by weight): Nitrate of ammonium, 68-64; di-nitrobenzol, 15-13; chloride of sodium, 21-19; moisture, 1. Permitted weight of charge, 18 ounces.

Faversham Powder No. 2—Composition (parts by weight): Nitrate of ammonium, 48.5-45.5; nitrate of potassium, 25-23; tri-nitrotoluol, 11-9; chloride of ammonium, 19.5-17.5; moisture, 1. Permitted weight of charge, 24 ounces.

Kent Powder—Composition (parts by weight): Nitroglycerin, 25-23; nitrate of potassium, 33.5-30.5; woodmeal (dried at 100 deg. C.), 31-28; oxalate of ammonium, 11-9; moisture, 6-3. Permitted weight of charge, 32 ounces.

Monarkite—Composition (parts by weight): Nitroglycerin, 13-11; nitrocotton, 0.5; nitrate of ammonium, 51-48; nitrate of sodium, 8.5-6.5; chloride of sodium, 26-23; starch, 5-3; mineral jelly, 2.5-1.5; moisture, 2. Permitted weight of charge, 26 ounces.

Monobel, No. 1—Composition (parts by weight): Nitroglycerin, 9.5-7.5; nitrate of ammonium, 70-66; wood-meal (dried at 100 deg. C.), 9-7; chloride of sodium, 16-14; moisture, 2. Permitted weight of charge, 10 ounces.

Swale Powder—Composition (parts by weight): Nitroglycerin, 20-18; nitrocotton, 1.5-0.5; tri-nitrotoluol, 5-3; perchlorate of potassium, 38.5-36.5; wood-meal (dried at 100 deg. C.), 10-8; oxalate of ammonium, 29-27; moisture, 2. Permitted weight of charge, 20 ounces.

The full list of permitted explosives will be given next week.

Half-Million Dollar Experiment Station Proposed for the Bureau of Mines at Pittsburgh

Plans for the proposed $500,000 experiment station of the U. S. Bureau of Mines, to be located in Pittsburgh, Penn., have been approved by the commission appointed by Congress for that purpose. The Federal Government now owns the property upon which will be erected a group of buildings, especially designed and adapted for the carrying on of the mine-safety work and other investigations in which the Bureau of Mines is interested.

Congress, a year ago, in the Public Buildings bill, authorized a new home for the Bureau of Mines, to cost $500,000. It is now expected that Congress, in its present session, will make a specific appropriation so that construction work may begin. It is hoped that contracts may be let by July 1.

The commission that approved the plans consists of J. A. Holmes, D. C. Kingman, chief of engineers of the U. S. Army and O. Wenderoth, supervising architect of the treasury. The State of Pennsylvania has appropriated $25,000 for coöperation in establishing this experiment station, and has appointed a state commission, consisting of James E. Roderick, chief mine inspector, Dean W. R. Crane, of the mining department, Pennsylvania State college, and W. H. Caverly. This latter commission has tentatively approved the plans.

The proposed site consists of nearly 12 acres of land, part of it on the higher level of the city streets and part of it on the level of the B. & O. R.R., which will furnish adequate facilities for passengers and freight traffic.

The group consists of three main buildings. The central building of the group, the mining building, will be three stories in height, flanked by two other buildings, one the mechanical, and the other the chemical building. In the rear of these, and inclosing a court, will be the service building. Beyond the service building, and spanning what is known as Panther Hollow, thereby connecting the Bureau of Mines buildings with the Carnegie schools, will be two buildings, over the roofs of which will pass the roadway from Forbes St. to the Carnegie schools and Schenley Park.

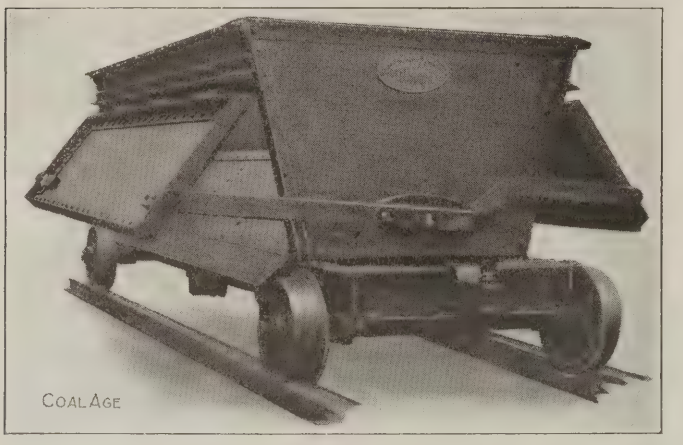
Between the main group and the power and fuel group, will be the entrance to a series of mine shafts. One of these will be used as an elevator to carry heavy material and passengers from the lower level to the upper; another will be for tests of hoisting ropes and similar mining appliances; another will be an entrance to tunnels extending under the buildings and in which mining experiments, such as fighting mine fires, will be conducted.

The portion of Panther Hollow above the power buildings will be arranged as a miners' field, the slopes of the ravine being utilized as an amphitheater, which will accommodate 20,000 spectators, who may assemble there to witness demonstrations in mine rescue and first-aid.

The main, or mining, building will contain the administrative offices, and those of the mining force.. In it will be an assembly and lecture hall, a library, smoking room and other rooms for demonstrations and training in mine rescue and first-aid. The mechanical building will be for experiments and tests of mining machinery and appliances; and the chemical building for investigation and analyses of fuels, explosives and mineral substances.

The buildings now used by the Bureau of Mines as an experiment station, at Pittsburgh, were loaned by the War Department, as an emergency measure, when the Bureau was created. The War Department has suggested that it now needs its own buildings and it is felt the Bureau cannot retain possession much longer. The buildings are very old and are entirely unsuited to the needs of the work. It is said that the investigations have been seriously handicapped by the inadequacy of the structures now in use.

PROPOSED NEW BUILDINGS OF U. S. BUREAU OF MINES



Illinois Miners and Mechanics Institute

Recognizing the importance of the coal industry in Illinois, the legislature of that state has authorized the establishment of an institute designed "to prevent accidents in mines and other industrial plants, and to conserve the resources of the state." The administration of the institute is vested in the trustees of the State University. The trustees have appointed a director and have placed the institute under the general supervision of the Department of Mining Engineering of the University of Illinois. The chief purpose of this institute is to serve the employees of coal companies who wish to attend a short course on coal mining. The institute will, therefore, offer such a course beginning Apr. 6, and continuing until May 16, 1914. There is also a two-year course of systematic instruction, which is so arranged that a man will be able to continue full time at his work while engaged in acquiring technical knowledge. Bulletins can be obtained by addressing R. Y. Williams, Director, Illinois Miners and Mechanics Institute, Urbana, Ill.

A New Type of Automatic Dump Car

The Montgomery Coal Washing & Mfg. Co., of Birmingham, Ala., have placed on the market an automatic dump car, which seems to be an improvement on many types now in use.

The Montgomery company originally designed this car for removing the refuse matter produced in the operation of their coal-washing plants, but it has gradually found its way into use in many places where a monitor car is necessary, such as handling coal, stone, or ore down an incline, removing mine refuse, stocking coal, coke, etc., and removing boiler refuse.

NEW STYLE DUMP CAR FOR COAL MINES

While commonly employed on an incline where it returns by gravity, this car may be used equally well in connection with a tail rope or may be provided with a motor for self propulsion.

The car is provided with a friction wheel beneath the body which comes in contact with an ordinary 2-in. plank, spiked to the ties, thereby automatically opening and closing the doors; the doors being opened on its passage over the plank and closed and locked on its return.

By changing the position of the friction wheel and providing additional planks, two or more cars may be operated on same track and dumped at different places.

The Situation in Labor Circles

The current week has witnessed the adjournment of the Chicago conference, which involves the western Pennsylvania, Ohio, Indiana and Illinois districts, and the reconvening of the central Pennsylvania conference at Philadelphia.

The disagreement in the Western situation was the result of a deadlock regarding the elimination of Clause Three of the Cleveland agreement. The miners proposed that this agreement be used in its entirety, with the exception of this Clause Three, which they desire omitted. The operators would not accept this condition. This clause provides that no change in the agreement reached at the joint conference, which will in any way affect the cost of production shall be made by district organizations. The removal of this condition from the agreement would make it possible for local unions to demand an increase in wages at any time they desired.

District President Patrick Gilday, of District No. 2, United Mine Workers of America, with nine delegates, represents the union contingent at the new Philadelphia conference. They are still demanding a 10 per cent. increase for all day labor, the check-off, the mine-run basis, and that the operators pay the expense of pushing the mine cars. Up to the present writing, the deadlock has been as complete as at the two previous conferences, and there are no present indications that an agreement will be reached.

A Big Consolidation of By-product Companies

Otto Coking Co., Inc., has been formed to operate in the United States, and, on Mar. 1, 1914, took over the organization, assets and good will of the Schniewind Coke Oven Co., the United Coke and Gas Co., the German American Coke Co. and the American Coke and Gas Construction Company.

The Otto Coking Co. is controlled by the interests in Dr. C. Otto & Co., of Dahlhausen a. d. Ruhr, Germany, and the Otto Byproduct Coke Co., of Leeds, England. The object is to introduce into the United States the Otto Regenerative Oven, with direct recovery of ammonia, tar and benzol.

The new company starts out with a contract for the immediate erection of a plant for the Buffalo Byproduct Coke Corporation, at Lackawanna, N. Y., near Buffalo, with several other negotiations now going on for additional plants.

The permanent officers of the new corporation will be Dr. M. G. Christie, Leeds, England, President, who will spend about half his time in this country; Dr. C. Otto, Assistant to the President, who will shortly take up his permanent residence in this country—Dr. Otto being the son of the inventor of the original Otto oven. The Vice-President and General Manager will be Mr. Louis Wilputte, one of the best known coke-oven engineers in America. The Secretary and Treasurer will be George F. McKay. The temporary offices of the corporation will be at No. 6 Church St., New York City, where they occupy the entire seventh floor.

Itinerary of Federal Rescue Car

EVANSVILLE CAR No. 3

Arrive	Leave	Address
1914		
March 23	March 28	Boone, Iowa
March 30	April 4	Colfax, Iowa
April 6	April 11	Melcher, Iowa
April 13	April 18	Knoxville, Iowa
April 20	April 25	Ottumwa, Iowa
April 27	May 2	Albia, Iowa
May 4	May 9	Chariton, Iowa
May 11	May 16	Dallas Center, Iowa
May 18	May 23	Mystic, Iowa
May 25	May 30	Rathburn, Iowa

Erratum

In our issue of Mar. 14, p. 437, referring to the capacity of air to absorb moisture, the following statement is made: "It practically doubles with every 250 deg. F." This should be: "with every 20 deg. F."

COLLIERY NOTES

In Illinois, there are 79,411 men working in and about the coal mines. Only two other states have a larger production of coal, and in no other state is there as much unmined bituminous coal as there is in Illinois.

A good light at the pit bottom and along main haulage roads is very necessary. Where the lighting is done from power circuits, bulkhead and well-glass fittings, hermetically sealed and protected by wire guards, and connected five in series on 500 volts, make a satisfactory arrangement

European experience in colliery operations is tending to prove that it is advisable to have two winding drums instead of one to each shaft; when this plan is followed, the two cages in the shaft can be raised and lowered independently of one another. German experience along this line has shown conclusively that in working thick seams of coal, a much larger output can be obtained by the employment of two drums.

Editorials

Miners' Union Opposes National Guard

The Illinois division of the United Mine Workers of America assembled in convention at Peoria on Feb. 27, and by a vote almost unanimous adopted a resolution condemning the National Guard as maintained in the various states, and urging all labor unions to do everything in their power to discourage their members from allying themselves in any way with the state soldiery.

It was pointed out in justification of this resolution that in all industrial struggles the National Guard had opposed and often frustrated the designs and practices of union labor.

So far as we are aware, the National Guard of Illinois has never been called into service, except for the protection of life or property. No law-abiding citizen, or group of citizens, has aught to fear from this most powerful and efficacious weapon of the commonwealth—the last resort of the chief executive. This antipathy to our military organizations now displayed by the United Mine Workers causes us to doubt the sincerity of their desire to act within the bounds of the law.

Religion and Coal Mining

We readily grant that in admitting the Sunday schools of Palos, Ala., to our columns, we depart somewhat from the rules which regulate the technical press and we do not expect to do this frequently.

It is needless to say that the difficulties in many towns arise largely from a disregard of that essential element in human progress—religion. If the reader doubts the importance of this factor, we would refer him to Benjamin Kidd's "Social Evolution," to prove the effect of the religio-ethical element in the progress of civilization.

As he points out, the resistance of the classes which possessed formerly the sole right to vote, to an education and to political preferment, have been broken down by the surrender of the more liberal members of that class to the nonrational or religious arguments presented. The poorer people have always been largely and most successfully led in their opposition to the richer not so much by the members of their own class as by the more ethical elements in the very class whose privileges were thus threatened. It is true today that the more arrant forms of capitalism are most menaced by protagonists found among the capitalists.

The appeal is always to rights and not to force and the world moves steadily along. If the nonrational appeal is of no value, why do the labor unions so continually use it? They rarely say we can do thus and thus, but rather that public opinion demands this or that. Each side from the beginning appeals to public opinion, a motive power not rational, but moral.

But what is the virtue of the church and religious school? Men meet in political assemblies to reform *others* by force of law; they assemble in labor unions to restrain and compel capitalism by strikes, sabotage, demonstrations and blacklists. The operators meet and weary each other with condemnations of the workmen. These assemblages are all conventions of protest. They aim to regenerate the other fellow.

Your religious meeting is different. It is almost always for self-regenerative purposes and consequently marks real progress. We can conceive that as a result of increasing religious opportunities, our sociological campaign will move more rapidly, but certainly with less friction and clamor. When both parties, employer and employed, have their minds centered on their own particular shortcomings, those evils which threaten to convulse the state will have no place to hide.

Therefore, we hope that churches and Sunday schools will grow and flourish in our mining towns and incidentally smooth the paths of industry and advance the coming age of mutual help.

Playing to the Grandstand

The juggling of words, the distortion of fact, the placing of a subject in false perspective in order to win the plaudits of the multitude, are rhetorical tricks perhaps as ancient as the transmission of ideas by articulate utterance. The demagogue and agitator stoop to any means however perverting in order to "be in with the crowd." So long as such people can "play to the grandstand," they stop at nothing.

A Pittsburgh newspaper, under date of Feb. 13, prints the following editorial:

> Just as soon as these mining troubles are looked at by other than local eyes, carefully adjusted to viewing conditions through them and no others, a new picture is given to the public. It was so in West Virginia, it is so in Michigan, and it will be shown to be so in Colorado when the Federal investigators have completed their work.
>
> The Federal commission on industrial affairs has just reported that the troubles in the copper-mining regions of Michigan are due solely to the mine owners. That is what the senatorial committee reported in the case of the West Virginia coal miners. It is what the congressional committee now at work in Colorado will report.
>
> The Federal commission in its report gives the Western Federation of Miners an excellent bill of health. The report confirms what was said by the striking miners in Michigan—that the trouble was because the mine owners refused to treat with the miners' organization, or recognize any of its officers. Therefore, the long battle, and bloodshed, and wanton slaughter of 72 women and children at Calumet, was only for the legal rights that every man has.
>
> Of course, bound up in that is the right to defend themselves economically, but that is exactly what the mine owners have done. The main difference is that the miners organize to defend their lives, while the mine owners are compactly bound to exploit miners and public. But the question of right to organize is the one issue in the copper strike.
>
> That is what was found in West Virginia, and what will be reported by the congressional committee in Colorado. The miners simply want to exercise their right to defend themselves. If the Western Federation of Miners, or the United Mine Workers is unlawful, or unlawfully conducted, that is a matter for the legal authorities to deal with, not the mine owners' organization. Organizing for self-protection is not a crime, and the mine owners cannot make it one.

But—it is a **crime to shoot and deport, and "bull pen"** men, women and children, to trample them to death in a panic in a crowded hall, and starve them for trying to defend themselves. There is the crime.

We call particular attention to the statement in the third paragraph: "The trouble was because the mine owners refused to treat with the miners' organization or recognize any of its officers. Therefore, the long battle and bloodshed and wanton slaughter of 72 women and children at Calumet was only for the legal rights that every man has."

O tempora! O mores! Is it the inherent right of citizenship, is it the privilege or duty of the wage-earner to make of himself a veritable "dog in the manger?" to say to his fellow workmen and the world at large, "I will not work except under such and such conditions and you shall not accept that which I refuse?" Is there any law, statute or custom which requires any employer to treat with—much less recognize as "it"—any "officer" or organization of or among his employees?

"The miners organize to defend their lives"—human life cannot be jeopardized unless there be a source of danger. We note that the periodical quoted is silent as to the nature of this peril to the workingman's existence. Was it the musket or the lash, or was it a purely fanciful grievance, the offspring of some organizer's lurid imagination?

No sane, logical, thinking individual will question the right of any class of men to band themselves together for mutual enjoyment or advantage. When, however, the activities of such an organization run counter to the laws of our nation, when its members—whether right or wrong in their contention—resort to riot and intimidation, they must not blame the mine owner if the consequences of their indiscretion are both copious and bitter.

It is just as foolish and narrow to believe that the mine operators are always right in their contentions as as it is to believe that every miner is a saint with a through ticket for heaven. There isn't any higher percentage of virtue among coal men, high and low, than there is among the people engaged in other industries. Every move on the part of each class—employer and employee—must be considered fairly and without bias, if commerce and industry in America are to be advanced on lines of justice and truth. The greatest harm is sure to come from always approving or condemning without question the action of either party in a labor conflict.

At the present time unionism has become so widespread that regardless of fact, regardless of all principles of recitude or equity, regardless of property right, regardless of the time-honored laws of *meum* and *tuum*, the crowd must be catered to. Our Pittsburgh contemporary has "played to the grandstand."

The Union

In most of the coal states the "Miners' Union" has come to stay. The operator does not face the question whether he wants unionized or ununionized conditions, but what sort of men are going to lead the organization and what demands these men are going to make. Nor let anyone doubt that the men of the Union are going to make demands and not assent readily to the operator's wishes in mine regulation.

These are facts and to them the operator should not oppose mere bluster. Unkindly remarks about the Union only make the hard-working intelligent miner realize that the operator dislikes the Union from its president to the more humble pit committeeman. The more intelligent miner, therefore, is not disposed to incur the ill-will of his employer, and as a consequence, he keeps out of union activity, permitting the radical irreconcilables to entirely rule all labor councils.

We confess that a better spirit on the part of the operator might induce many men of fair mind and honest purpose to seek for union preferment. We do not suggest that the operator, quietly or otherwise, urge men of extremely conservative mold to run for office. Such men are too reactionary to lead. But men who know what is right, and who will stubbornly resist an unjust course on the part of either operator or miner, should be encouraged to seek the best places in the Union.

It is time for the public good that we should have men in the operating positions and in the Union, who will make development in mining more rapid by making it more profitable to both owner and miner. If the differentials be small, or if they be refused when machines of larger capacity are introduced, when coal conveyors are installed, when longwall systems are put in force and other changes are made, no progress will be possible.

If merchants and manufacturers acted like many union officials now act, we should still live as our fathers did. Advantages must be split between the buyer and seller, otherwise the buyer will not purchase or the seller deliver.

An opportunity for real statesmanship exists in the Union—a measure of good judgment, which will make money and easier conditions for both parties. Greediness, such as usually distinguishes the mine owners and the Unions alike, after a bitter struggle, never makes for efficiency. A new union, unlike a new broom, does not sweep clean. The "foxiness" exhibited on both sides generates suspicion, and improvements in mining methods are impossible, while men of real ability and sterling character are by reason of the many disagreements prevented from engaging themselves steadily in the executive service of either operator or miner.

The Chief Cause of Mine Accidents

In a letter to Doctor Holmes, President Moorshead, of the Illinois Coal Operators' Association, says:

I think you will agree with me that it is not so much for the want of laws that we suffer, as it is for want of respect for them. I do not mean that we should not have better appliances and more modern equipment generally, but I do contend that back of all our more serious accidents is the disrespect for law and authority.

We cannot hope for a better state of affairs until convictions in the courts for violation of the laws are more general, and this will not be until greater powers are given to inspectors and superintendents so that they may be able to arrest men who openly violate instructions.

Mr. Moorshead has here put his finger on the sore spot of the coal industry. Lack of discipline will destroy the most magnificent organization, and there cannot be discipline where there is not both fear and respect for the law. Let everyone insist on the enforcement of all our present mining regulations. The result will be that ill-advised legislation will be corrected, and in the end fewer fatalities will be recorded. There is no more certain way to cause the repeal or amendment of an unfair and unjust law than to insist on its strict observance.

Sociological Department

Method of Rendering First-Aid

By A. S. Snyder*

SYNOPSIS—A discussion of the most effective methods of rendering first-aid-to-the-injured in the more frequent types of mine accidents—as the breaking of a limb or the back—and practical suggestions regarding the best procedure in event of such accidents.

The first thing to learn in first-aid methods is to tie the reef, or square, knot. It is well to learn to tie a reef knot and thereafterward use that method for tieing all knots in whatever you do. They are as easily tied as the granny knot, look better, are more secure and more easily opened.

Neatness is another factor in first-aid practice which requires considerable attention. Even the most simple bandage for an injury of the finger should be applied with neatness, as it will impress the injured with confidence in the person attending the injury. Furthermore, if bandages are applied neatly, they naturally fit the parts to which they are applied better than if put on in a slouchy manner, and the result is that this precaution adds to the comfort of the injured person.

In rendering first-aid-to-the-injured, always keep this thought well impressed on your mind, "Whatever you do is to make the injured person as comfortable as possible and to prevent the injury from becoming more serious, until medical aid can be secured."

Fractured Limbs

Before moving an injured person, be sure to treat the injury in such a manner as to prevent further injury. In fractures of bones of the limbs, secure them with well padded splints, being careful not to have undue pressure at the point of fracture, as that would cause unnecessary pain. Pad on each side of fracture, and place one bandage on each side of fracture around splints.

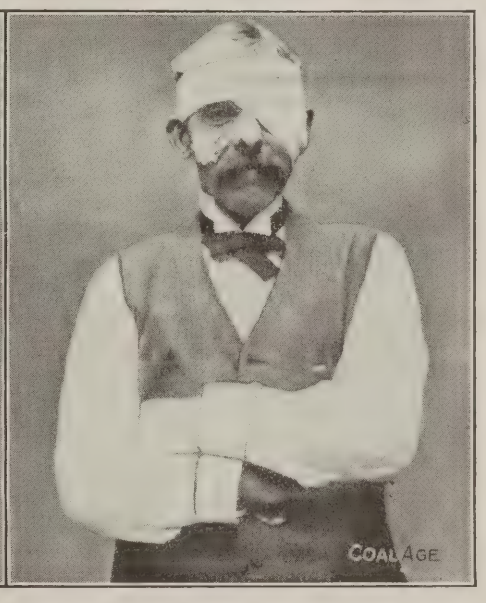
In fractures of the lower leg, have the splints long enough to reach above the knee and secure them there with a bandage, to prevent any movement at the knee.

In fractures of the thigh, the outside splint should be long enough to reach from the armpit to the foot, and the inside splint, from the crotch to the foot. Place one bandage around the splints on each side of the fracture, one below the knee, one around the hip and outside the splint, and one around chest. Use one bandage to tie the feet together and one around both legs at the knees. In all, seven bandages are required.

In fractures of the middle, or upper third, of the upper arm, always apply the splints so as *not* to interfere with the elbow—one splint to the inner and the other to the outer side of arm, permitting them to extend down to the end of the elbow. If of the lower third of upper arm, it is best to use a triangular splint and secure the upper part of the upper arm rigid with the forearm.

In fracture of the forearm, have the splints reach from the end of the elbow to the tips of the fingers, and apply one bandage above the fracture and one below, starting the lower bandage in palm of hand, making a figure of 8 on back of hand and securing the ends above wrist.

When applying splints or bandages to any part of the hand or arm it is best to hold the arm in the position in which it is to be carried—it being understood that the arm should always be placed in a sling.



For fracture of the wrist or bones of the hand, secure with splint in palm of hand, letting it extend back some

*Berwind-White Coal Mining Co., Windber, Penn.

distance along the arm, so as to keep the hand rigid.

For fracture of the bones of the fingers, apply a small splint on the inside of the injured finger, or a piece of cardboard on each side.

Broken Back

A broken back is one of the most serious injuries with which a first-aid man comes in contact. The condition of the injured person is not always the same; their position after the accident is not the same; the degree of the injury is not the same. But in all cases the injured persons have to be handled with great care so as not to cause any further injury to the spinal cord. It is first necessary to place the injured persons on their back, after which the following described method of treatment has been approved by first-aid men and physicians everywhere.

Use two boards, 5 or 6 in. wide, placing them under the injured person, one on each side, being careful to pad the boards well beforehand. The best method of placing these boards under the patient, in order to prevent unnecessary movement, is for three persons to raise one side of the body high enough to slide one board under that side, parallel to the spine and about 1½ in. from center of spine; then raise the other side in the same manner and slide the other board under that side. The boards should be placed in such a position that they are about 3 in. apart, one on each side of the spine. The boards should be a little longer than the patient, if the ambulance or conveyance will permit. Cross pieces should then be placed under the two boards and securely tied to them at each end. The cross pieces should extend out far enough to serve as hand-holds in carrying the patient.

The injured person should then be securely tied to the splints by placing bandages around both the body and the splints; one about the chest and one around the hips. Each leg should also be tied to the splint on which it is lying. Special care is required to pad the boards or splints properly beforehand, so as to make the injured person as comfortable as possible.

I have seen a number of methods demonstrated and have heard descriptions of others I have not seen, but the above method seems to be the most satisfactory in every way. In case of a broken back it is required that persons treating the injury must use such judgment as is always required in emergency cases. When possible the treatment and moving of the injured person should be under the personal direction of a physician, and a physician should always be sent for at once.

Compound Fractures

The first thing to note in cases of compound fractures, as in other wounds, is, whether the hemorrhage is severe or moderate. If severe, it must be checked at once. Great care must be exercised to prevent infection. Clothing must be removed and a surgically clean dressing or gauze applied to the wound. This dressing must thoroughly cover the wound. If the end of the bones protrude through the skin, no attempt to replace them should be made, but the dressing and splints and bandage applied just as they are. The rest should be left for the physician, who should be notified immediately.

The clothing should always be removed from an injury in examining it, as no injury can be intelligently treated until its nature is known. In removing the clothing, it is best to cut it along a seam.

Varieties of Wounds

Any injury in which the skin is pierced or broken is called a wound. There are four general varieties of wounds, as follows:

1. An incised, or cut, wound, is a clean cut made by some sharp instrument, such as a knife, razor or piece of glass.
2. A lacerated, or torn, wound, is where the tissues are torn rather than cleanly divided, as in the case of an incised wound.
3. A punctured wound is generally small but deep, and may be caused by such instruments as a needle, nail, stiletto or pick. Bullet wounds are also classed as punctured wounds.
4. A contused wound is a bruise generally caused by a fall or by a blow from some blunt instrument.

A Sunday School at Palos, Ala.

When the Palos Union Sunday school was organized, August, 1912, its leaders realized that to make it a success, it must be an interdenominational body, as there were not enough members of any one creed for separate schools. When it was first organized, there were about 25 pupils present, but from the first the school has continued to grow, until now the enrollment reaches 200, with an average attendance of 100 pupils.

A special effort has been made to increase the adult Bible class, since September, 1913, and this endeavor has been most successful. There are on the roll 80 members, with an average attendance of 45, the largest number

The Palos Sunday School with the Superintendent in the Center of Foreground

present at any one time was 64, only 4 of whom were visitors, the rest being regular scholars.

The class name is Good Fellowship, and the emblem is the regular button with white center, around which is a red border; the class has membership, social and devotional committees. The membership committee look after new members and the absent ones, when they stay away more than two Sundays in succession; the aim being to help those that are in need of help—morally, spiritually or otherwise.

W. W. Kicker, mine superintendent, is in charge of the Sunday school. The method of organization of the adult Bible class and the name by which it is known do away with the idea that is a one-man class. Everyone feels that the class is his and not the teacher's private

THE GOOD-FELLOWSHIP CLASS AT PALOS
(Superintendent on left of second row from front.)

institution, in which he is introduced merely as a listener. The school is composed largely of miners and their families, but a number of farmers and business men in other walks of life are members.

It is an inspiration to any one to visit the school, and see the large number of men, women and young people in attendance. The school contains 106 members, and the Good Fellowship class has 46, as will be seen in the photographs.

Our little town of Palos is a well conducted village. The company which is the Republic Iron & Steel Co., does not permit the sale of whiskey and will not retain a man who gets drunk in its employ, nor will it permit drunkenness in any of its houses. Last Christmas not a drunken man was to be seen anywhere on the premises. The company employs about 200 men and they are of the best class.

Loyalty to Contract Obligations

By GEORGE N. LANTZ*

Patrick Gilday, president of District No. 12, United Mine Workers of America, is to be complimented on his boldness in advocating a penalty for breach of contract between miners and operators.

It requires a certain amount of courage to suggest the imposing of a fine for the misconduct of those who elect one to office. Especially is this true in the case to which I refer, inasmuch as the miners' union has always been known to be opposed to such a course. However, the action of President Gilday, in this matter, serves to emphasize the need of something of the kind. While not being troubled with the "button strikes" that have so frequently occurred in Pennsylvania, the miners in Ohio often go on strikes to settle matters that might easily be adjusted otherwise by the exercise of a little patience and good judgment.

The agreement between operators and miners provides that workmen shall not stop the mines, except for the breaking down of the scales or the refusal by the company to pay the miners on pay day. It is mutually agreed that either of these causes furnishes a sufficient excuse for the miners not going to work. A strike occurring from any other cause, whether otherwise justifiable or not, is clearly a breach of contract on the part of the miners. The fault may or may not rest wholly upon the miners, but may be the natural result of some injustice or unexplained action on the part of the operators. The terms of the contract, however, give no choice or option in the matter. The miners must continue to work if they would be *loyal to their contract. That the abrogation of a contract by one party thereto is a crime that should not be lightly regarded, all must allow.*

The inauguration of a system of fines for breach of contract would generally require the appointment or election of a board to interpret the meaning of the contract in different cases. If that board is well chosen and its duties clearly defined and it is understood and agreed that their findings shall be final, it will do much to eliminate friction between the parties to the controversy. The same board or a similar one might, also, decide a number of other matters that are local and cannot be specified in an agreement affecting whole states or districts. Among these may be mentioned: The eligibility of bosses for membership in the union; payment for "dead work"; removal of impurities from coal loaded in the mines; overtime and Sunday labor; payment for fractions of hours, and a number of other like matters that are often in dispute. The work of such a board, if properly systematized, might render disputes less frequent, as many questions would be governed by precedents previously established. The tendency would be greater coöperation between employees and employers, which is greatly needed.

*New Straitsville, Ohio.

Recent Legal Decisions

Injury Caused by Breaking Cable—A coal miner, who was injured through breaking of a cable used in drawing cars up an incline, was not necessarily guilty of contributory negligence in attempting to cross the track before the cars had passed. (Texas Court of Civil Appeals, Burnett Fuel Co. vs. Ellis, 162 Southwestern Reporter 911.)

Warning Miners against Existing Dangers—A mining company was not relieved from liability for injury to a miner, caused by the falling of part of a mine roof, because he was warned of the danger, if it was not his duty to prop the roof. (Kentucky Court of Appeals, W. G. Duncan Coal Co. vs. Thompson's Administrator, 162 Southwestern Reporter 1131.)

Injury Caused in Blasting—Scope of Miner's Employment—A coal-mining company cannot escape liability for injury to a miner, caused by fall of part of a mine roof due to shooting of nearby coal pillars, by showing that he was given no assurance that no shots would be fired. But that is a circumstance bearing on the question whether or not he assumed the risk of the accident. A miner engaged in replacing a canvas curtain which was used to divert fresh air into his working place, and which had fallen, was not acting outside the scope of his employment, as affecting his employer's liability for injury received while he was so engaged. (United States Circuit Court of Appeals, Eighth Circuit; Victor-American Fuel Co. vs. Peccarish; 209 Federal Reporter 568.)

Discussion By Readers

Widths of Opening and Pillar

Letter No. 1—Referring to the inquiry of Thomas C. Miller, COAL AGE, Feb. 28, p. 379, I desire to submit the following for consideration, believing that the further discussion of this question may be of special interest, not only to Mr. Miller, but to COAL AGE readers in general.

The answer given to this question in COAL AGE, at the time of its publication, is correct, as far as it goes; but in my opinion, certain important considerations have been overlooked. 1. The action of the dynamic forces that are set up when the sandstone and other overlying strata break to the surface as a result of robbing is not considered. 2. The extra loading due to the cantilever action of the roof on the pillars is overlooked.

The pillars must always be large enough, not only to support the superincumbent strata, but to provide against the conditions just mentioned. For economical mining, experience dictates that frequent resort must be made to "slabbing" or splitting of the pillars, in "robbing." This practice avoids the expense of cleaning up heavy falls of roof at that time.

Mr. Miller expresses the opinion that no falls of a serious nature will occur; but, at Rhodda, on Preacher Creek, and in other mines of the Stonega Coal & Coke Co. reported to be working the same seam of coal in the same locality, frequent areas of bad roof have been encountered; and it seems probable that the same conditions may later be found to exist at Benham, in which case it may be expected that the pillar work will be congested by falls of slate.

In the practice of robbing pillars, there is always a portion of the pillars that must be extracted before the roof breaks through to the surface. At times, this area of unsupported roof will cover an acre, and of necessity an excessive load is thrown on the pillars along the robbing line. The additional width of pillar required, under these conditions, is determined by assuming that the overhanging roof forms a uniformly loaded cantilever, extending from the robbing line to the last break in the gob. As the pillars are drawn back, the length of this cantilever increases until another break occurs over the pillar. A severe dynamic load is thus thrown on the pillars at intervals. Experience seems to dictate that the dynamic forces thus set up and the cantilever load acting on the pillars are as great as the dead load due to the superincumbent strata. If this be true, instead of 20-ft. rooms on 40-ft. centers, there should be driven 20-ft. rooms on 60-ft. centers.

Assuming, however, as Mr. Miller states, the pillars in the lower seam will stand for years, provision should be made for splitting the pillars, in robbing. These splits are seldom driven less than 16 ft. wide, and the original pillar should be, therefore, increased at least this width, making it necessary to drive 20-ft. rooms on 80-ft. centers. The dimensions given above are in common use in the Pocahontas field.

Again, it must be remembered that if the pillars are not mined clean, eccentric loading will occur, regardless of dimensions, in which case a squeeze is almost the inevitable result. For this reason, all mining should be conducted on the panel system, or some modification of the same that will provide large barrier pillars, at frequent intervals in the mine, and prevent the spread of a destructive squeeze throughout the entire workings. With proper supervision, over 95 per cent. of the coal in seams may be extracted at a reasonable mining cost.

As was stated in COAL AGE, in answer to this inquiry, "There are many factors that influence and modify the width of pillars and openings; and, while much value attaches to a theoretical analysis of the question, careful consideration must be had for such features as tend to lessen the strength of the pillars by softening the coal or the underlying stratum, or by producing a grinding action that would crush and weaken the pillars. The existence of gas in the coal or the strata adjacent thereto, or the presence of water, will tend to weaken the pillars and must be considered in studying this problem, as also any considerable inclination of the seam."

It should be the aim of every coal operator to conduct his operations in such a manner, that not only he, but the miner also, may reap the maximum return, for the minimum of energy expended. A recent study of room widths, for the purpose of trying to determine the most economical width of opening to adopt, would indicate that a 20-ft. room in a seam 5 ft. 6 in. thick, under conditions existing at Benham, is wasteful of the miner's energy and requires more than the minimum amount of explosive per ton of coal produced.

Indications of Gas on the Carbide Lamp

Some time since, mention was made in COAL AGE, Vol. 4, p. 27, of the behavior of the flame of an acetylene lamp in the presence of carbon dioxide. Warning has frequently been given of the increased danger to miners using carbide lamps, by reason of a greater depletion of the oxygen of the air being necessary to extinguish this lamp. The argument is advanced that the carbide lamp continues to burn in at atmosphere in which other lamps are extinguished.

In investigating this question for myself, I made careful observations in an abandoned entry from which the ventilating current had been excluded. My experiments led to the discovery of a phenomenon that I have never heard described or mentioned, and it occurs to me that the results might be of interest to the readers of COAL AGE. I believe it is the duty of any man who stumbles blindly onto facts that may be of value to his fellow workers or add to their common safety, to make these known and, with this purpose in view, I submit the following:

It may not be generally known that a much smaller percentage of marsh gas (CH_4) can be detected with an

ordinary carbide miner's lamp than by many of the safety lamps used for that purpose. I would first suggest that, in testing for gas with a carbide lamp, it is necessary to hold the lamp in such a position that the reflector will shield the eyes from the glare of the flame and care should also be taken to avoid the reflection of light from any surfaces in front of the lamp, as such reflection blinds the eyes so that the flame cap cannot be seen on the lamp. The best results are obtained with a large flame. In the presence of gas a luminous tail or cap extends outward and upward from the flame; which, in pure air, has a reddish tinge. I have found that a very small percentage of marsh gas, less than can be detected by the best safety lamp in use, causes this tail to elongate and take on a bluish tinge. When sufficient gas is present to give a cap varying from ¼ to ½ in. on the safety lamp, the cap on the carbide lamp will appear alarmingly large and wicked.

Having observed this fact by accident, I adjusted a carbide burner within the combustion chamber of a safety lamp, at the same time providing a shield to protect the eyes and permit the better observation of the cap. I found, however, that whether using a Davy lamp or one of the Clanny type, the reflection from the gauze or glass so blinded the eye that the cap could not be satisfactorily observed, and I concluded to abandon that attempt. Of course, the open carbide lamp cannot be used for ordinary testing purposes. But, when a test with a safety lamp fails to indicate the presence of gas, some surprising results may be observed on the open carbide flame, the tail of which is greatly elongated as the percentage of gas increases.

Interesting results were obtained in experiments with the carbide lamp in blackdamp. Entering a stagnant mixture, it was observed that there was enough marsh gas present in the upper stratum of air close to the roof to produce a faint cap ¾ of an inch long on a Wolf lamp. On lowering the lamp to within about 18 in. from the floor, the flame dwindled and it was necessary to raise the wick to avoid the extinction of the lamp. The lamp was then set on the floor and the flame was extinguished by the gas, which fact I consider indicated the presence of carbon dioxide and not simply an atmosphere deficient in oxygen.

The carbide lamp was now brought into use and developed a long cap that was much easier to observe than the ¾-in. cap on the Wolf lamp. On lowering the carbide lamp into the blackdamp at the floor, the flame was contracted and took on a reddish tinge. Its extreme brightness vanished and, instead of extending almost horizontally from the burner tip, as ordinarily, the end of the flame turned upward. Placed on the floor, where the safety lamp was extinguished, the flame of the carbide lamp continued to burn, though with less volume and brightness; and the outer third of its length was turned upward almost vertically. The carbide lamp was now advanced into a stronger mixture of blackdamp where it was necessary to increase the supply of water to maintain the flame. In this position, however, the flame went out suddenly, instead of gradually growing less and being finally extinguished, as is the case with an oil lamp.

In reporting these observations that seem to be of value, I would suggest that, although an experienced observer will learn to detect readily a lower percentage of blackdamp on a carbide flame than what would be fatal to life except by long exposure to its influence, the wisest plan is to use an oil lamp where blackdamp is suspected, because of the greater sensitiveness of the oil flame to extinction in this gas. I have offered the information, believing it to be valuable to a person who ordinarily uses a carbide lamp and who may unexpectedly encounter blackdamp, which would escape his notice but for this knowledge.

Coal Mining in England, Past and Present

I have been greatly interested in the recent references, in Coal Age, to the efforts now being made to increase the safety in mines by suitable and much needed mine legislation and the certification of mine officials. It brings to mind some observations that I made on a three months' vacation trip in old England last summer, after an absence of ten years in this country.

Mining conditions there have greatly changed. Doncaster, in South Yorkshire, ten years ago was a sleepy farming town of little importance, except for its far-famed butterscotch and the annual horse-racing events. Today, it is a busy thriving mining center and contains some of the best equipped mines in England. Among these may be mentioned the Dinnington Main Colliery, the first English mine to be equipped with a wireless system of signaling underground—a German invention installed by a German firm. Here, also, is the Bullcroft Colliery, another finely equipped mine, the headgear being supported above the shaft on massive concrete arches. This mine is equipped with 3000 Ceag electric lamps. No open lights are allowed in the mine, which is the case, also, in a number of other mines in this locality. By the use of the electric lamp, the operators hope to reduce the prevalence of the miners' nystagmus, with which a large number of miners are afflicted in safety-lamp mines. Under the English law, miners suffering from this disease receive a certain compensation during incapacity, as provided by the Employers' Liability Bill.

At the Micklefield Colliery, in Yorkshire, a great transformation has taken place. New shafts have been sunk and new seams developed. But the most striking feature of all is the clean appearance of the surface plant, these mines being operated solely by electricity. No boilers, smoke, or escaping steam are in evidence. The buildings are of artistic design and the grounds surrounding them are laid out with shrubs and flowers. The coal, as hoisted, is transported to a distant point, where it is loaded on the railway cars. The entire plant is one of the most modern in England. The electric hoists employed are considered far superior to the old steam hoists.

The credit for these changes is to be attributed largely to the new Mines Act and the new mining rules and regulations put in force at the mines. The "Safety First" idea has been made a fundamental feature of the new law, which fact has greatly reduced accidents at mines where these laws are strictly obeyed.

Aside from these improvements and in strong contrast thereto, I regret to say the actual mining conditions underground have made little, if any, advance. My observations lead me to attribute this fact to the supplant-

ing of the practical mine managers of 15 years ago, with young men—a class known in England as the "Articled Pupil." These young men are generally the sons of the middle classes. By the payment of a certain sum, they are permitted to take a five years' course of study and apprenticeship, under the direction of the company's officials. They learn a little about surveying and accompany the officials in their daily rounds of inspection, asking questions and picking up such information as they are able to understand. At the end of the allotted time, they are given an examination which is more technical than practical. Having passed this examination, they remain with the company until a vacancy occurs.

Under this prevailing condition, I am sorry to say that the man who has worked hard in various capacities in the mine and, by constant effort and study, has fitted himself both practically and theoretically for the work, has scarcely any chance at all. He is only permitted to act as an instructor, to educate the "articled pupil" in practical mine work and help him out when later he becomes manager. As a consequence, it is not surprising that these older and more practical men simply perform their duties, as required by law, but, beyond this, manifest little interest in the welfare of the company. They are not allowed to develop any scheme of their own and their suggestions generally meet with a cold reception, the credit for the same, if the suggestion is used at all, going to the man higher up.

There is every evidence, in the mines, of wasteful expenditure and loss of useful material, owing to the lack of practical management underground. Timbers are left in the goaves; pack walls are poorly built; airways are choked by heavy falls, and the air current obstructed by sharp turns and long winding routes. While there are some good main haulage roads, the tracks in the cross gates and on stallroads are crooked and badly laid. To make coal mining in England pay better, no prophetic vision is needed to see that there must be more practical and less theoretical ability underground. The present existing conditions in the mines are detrimental to the best interests of all parties concerned.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

General Potential of a Mine—An important application of the potential method, in mine ventilation, is the calculation of the potential value for the entire mine when the airways and shafts are of various dimensions.

Example—Calculate the general mine power potential in the following mine, shafts 1250 ft. deep:

			Area	Rub. Sur.
Shafts, upcast and downcast	8x10 ft.,	2500 ft.	80	90,000
Main airway ("A" seam),	6x10 ft.,	3750 ft.	60	120,000
Cross-headings ("A" seam),	6x 8 ft.,	2500 ft.	48	70,000
Tunnel to "B" seam,	5x 8 ft.,	500 ft.	40	13,000
Return air course ("B" seam),	5x14 ft.,	5500 ft.	70	209,000

Solution—The total power on the air, in any circulation, is clearly equal to the sum of the powers absorbed in the several sections of the mine, as expressed by the following general formula:

$$H = \frac{kQ^3}{K\,33{,}000}\left(\frac{1}{X_1^3} + \frac{1}{X_2^3} + \frac{1}{X_3^3} + etc.\right)$$

It will be readily observed that this general formula, for a mine of various sections (K being the coefficient of efficiency of the ventilator), is derived from the power formula

$$H = \frac{1}{33{,}000}\left(\frac{Q}{X_u}\right)^3 = \frac{Q^3}{33{,}000}\,\frac{1}{X_u^3}$$

But, since $1/X_u^3 = k\ s/a^3$ and k being constant, it is much simpler in using the above general formula, to factor and write k outside of the parenthesis, which makes each of the potential values within the parenthesis what may be called a "part potential" whose value is, omitting k,

Part potential $X_u = \frac{a}{\sqrt[3]{s}}$; and $\frac{1}{X_u^3} = \frac{s}{a^3}$

Now, calculating the value of $1/X_u^3 = s/a^3$, for each separate section of air passage in the mine given above,

Shafts, $\frac{1}{X_1^3} = \frac{90{,}000}{80 \times 80 \times 80} = 0.1758$

Main airway ("A" seam), $\frac{1}{X_2^3} = \frac{120{,}000}{60 \times 60 \times 60} = 0.5555$

Cross-headings ("A" seam), $\frac{1}{X_3^3} = \frac{70{,}000}{48 \times 48 \times 48} = 0.6380$

Tunnel to "B" seam, $\frac{1}{X_4^3} = \frac{13{,}000}{40 \times 40 \times 40} = 0.2031$

Return air course ("B" seam), $\frac{1}{X_5^3} = \frac{209{,}000}{70 \times 70 \times 70} = 0.6093$

Value for entire mine $\left(\frac{1}{X_0^3}\right)$ 2.1767

The part power potential for this mine is therefore

$$X_0 = \frac{1}{\sqrt[3]{2.1767}} = 0.7716$$

The Coal Age Pocket Book

Example—(a) From the part power potential calculated for the mine, on the preceding page, find the horsepower that will be required to circulate 30,000 cu.ft. of air per minute in a single current, assuming the ventilating fan to have a mechanical efficiency K = 60 per cent. (b) What water gage will be produced by the resistance in the mine, for this circulation?

Solution—(a) The required horsepower of the ventilator is

$$H = \frac{kQ^3}{K\,33{,}000}\,\frac{1}{X^3} = \frac{0.00000002 \times 30{,}000^3}{0.60 \times 33{,}000} \times \frac{1}{0.7716^3} = say\ 60\ hp.$$

(b) The mine water gage due to this circulation is

$$w.g. = \frac{kQ^2}{5.2\,X_u^3} = \frac{0.00000002 \times 30{,}000^2}{5.2 \times 0.7716^3} = 7.5\ in.$$

General Mine Potential, Equal Splits—It is possible to calculate the general mine potential when the air is equally divided one or more times, by simply multiplying the sectional area of the airway by the number of splits, as shown by the following example:

Example—A drift mine is opened on the triple-entry system. It is proposed to drive the main entries 7×10 ft. in section, a distance of 3000 ft. to the boundary. The cross-entries are to be driven double, 5x12 ft. in section and 1500 ft. to the side lines on each side of the main road, making in all 6000 ft. of cross-entries, including the returns. The main-return airways, on each side of the main intake are each 7x12 ft. in section and 3000 ft. long. Calculate (a) the horsepower on the air; and (b) the water gage produced.

Solution—The first step is to calculate the value $1/X_u^3 = s/a^3$ for each sectional division; thus

Main intake, 7x10 ft., 3000 ft. long: a = 70 sq.ft.; s = 102,000 sq.ft.
Two splits, 5x12 ft., 6000 ft. long: a = 120 sq.ft.; s = 204,000 sq.ft.
Main returns, 7x12 ft., 3000 ft. long: a = 168 sq.ft.; s = 114,000 sq.ft.

Substituting these values in the formula for finding the part potential value for each section,

Main intake, $\frac{1}{X_1^3} = \frac{102{,}000}{70 \times 70 \times 70} = 0.2974$

Two splits, $\frac{1}{X_2^3} = \frac{204{,}000}{120 \times 120 \times 120} = 0.1181$

Main return, $\frac{1}{X_3^3} = \frac{114{,}000}{168 \times 168 \times 168} = 0.0240$

Value for entire mine $1/X_0^3$ 0.4395

For the horsepower and water gage, we have

$$H = \frac{kQ^3}{33{,}000}\,\frac{1}{X_0^3} = \frac{0.00000002 \times 50{,}000^3}{33{,}000} \times 0.4395 = say\ 35\ hp.$$

$$w.g. = \frac{kQ^2}{5.2}\,\frac{1}{X_0^3} = \frac{0.00000002 \times 50{,}000^2}{5.2} \times 0.4395 = 4.2\ in.$$

FIREBOSS.

Meadow Lands, Penn.

The first question has recently been thoroughly discussed in COAL AGE, under the title Collapsible Stoppings. We shall be glad to receive the views of our readers in reference to the stonedust suggestion, in connection with the building of stoppings in mine entries.

Fan Ventilation

In a recent issue of COAL AGE, Jan. 24, p. 180, I noticed an interesting question in reference to operating two fans for the ventilation of the same mine in two separate sections, the return air from each section passing through the same return airway. I have a similar question that concerns our conditions here. It is as follows:

We are operating a mine that is extensively developed and in which the ventilation is becoming poor. The fan is producing, at the present time, 78,000 cu.ft. of air per min. against a 3.4-in. water gage. It has been proposed to install another fan, which will be a disk fan, 6 ft. in diameter, and which will ventilate a portion of the mine. Both fans, however, will be obliged to use the same return-air course for a distance of one mile, and both fans are to be operated as force fans or blowers.

The question is, Will both fans work successfully on this plan? I may state that the resistance of the main return-air course, at present, is equal to a 1.25-in. water gage. My own opinion is that the fan that is now in use will force air back through the portion of the mine intended to be ventilated by the small fan.

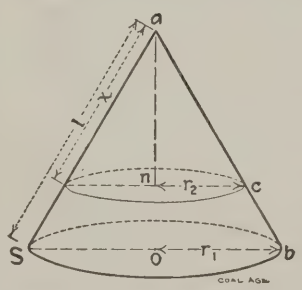
SUBSCRIBER.

Dayton, Penn.

In order to give an intelligent answer to this question, it would be necessary to know the length and size of the airways forming the two sections of this mine and the size of the main return airway. A plan should be given showing the present circulation and the proposed change. It is supposed that the present fan is a centrifugal fan capable of giving 78,000 cu.ft. per min. against a 3.4-in. water gage.

Though unable to offer an opinion of value, based on the data submitted, we may say that if a disk fan were to be installed in this mine, in order that it may assume its share of the work it would have to be capable of balancing the present installation. Under the ordinary conditions of mining, a 6-ft. disk fan would give, ay, 50,000 cu.ft. of air per min., against a water gage arying from 2 to 2.5 in. This fan would hardly balnce the action of the centrifugal fan now in use; and, s a result, we would naturally expect, as our correpondent has stated, that the present fan would still ontinue to force air into that portion of the mine inended to be ventilated by the disk fan. This is the est answer we can give with the information at hand.

Mensuration, Lateral Surface of Cone



Please answer the following problem in the columns of COAL AGE:

The slant height of a right circular cone is 2 ft. At what distance from the vertex of the cone must the slant height be cut by a plane parallel to the base, in order that the lateral surface of the cone will be divided into two equal parts.

FRANK DEWEY, Asst. Foreman,
Bast Colliery.

Ashland, Penn.

Referring to the accompanying figure, let $a\,b\,s$ be a right cone whose slant height $a\,b$ is indicated by l. It is required to find the slant height $a\,c$ indicated by x and determined by a plane parallel to the base of the cone and dividing its lateral surface into two equal parts. The lateral surface of a right cone is equal to the product of the circumference of its base into one-half its slant height. Denoting the respective radii $o\,b$ and $n\,c$ of the bases of these two cones, by r_1 and r_2, we have, from the terms of the question,

$$(2\ \pi\ r_2)\ x/2 = \tfrac{1}{2}\ (2\ \pi\ r_1)\ l/2$$

$$x = \frac{r_1\ l}{\quad}$$

Miscellaneous Questions

(Answered by Request)

Ques.—What power will be required for hoisting an output of 800 tons of coal from the inside parting to the bottom of the shaft, 5/8 of a mile, up an incline having a grade of 2 in. to the yard, allowing time for the return of the empties. The empty cars weigh one-half as much as the load they carry. The resistance of the cars is estimated as $^1/_{60}$ of the gross load and as much power is required to move the rope as to move the cars. The speed of the rope is 3 miles per hour; the working day, 8 hr.; and the cars are moving four-fifths of the time?

Ans.—The length of the incline, or distance of haul, is $5/8 \times 5280 = 3300$ ft. The speed of winding, or velocity with which the cars mave is $3 \times 5280 \div 60 = 264$ ft. per min. The time required for one round trip is $2 \times 3300 \div 264 = 25$ min.

Since the cars are running four-fifths of the time, and the working day is 8 hr., the total time of hoisting is $^4/_5$ $(8 \times 60) = 384$ min. Allowing 25 min. for each round trip, the number of trips per working day is $384 \div 25 = 15+$ trips. This would leave $384 - (15 \times 25) = 9$ min. of extra time to allow for unavoidable delays. For an output of 800 tons hoisted in 15 trips, the weight of coal hoisted per trip is $800 \times 2000 \div 15 = 106{,}667$ lb. Since the cars weigh one-half as much as the load they carry, the weight of cars is 53,333 lb. per trip. The total load hoisted is, therefore, 160,000 lb. per trip.

For a grade of 2 in. per yd., or 1 in 18, the gravity pull, or pull on the rope due to the grade is $160{,}000 \div 18 = 8889$ lb. In like manner, the pull on the rope due to the resistance of the cars is $160{,}000 \div 60 = 2667$ lb. This makes the total pull on the rope, 11,556 lb. The power required to move the rope being equal to that required to move the cars, the total load in the engine is $2 \times 11{,}556 =$ say 23,000 lb. For a speed of winding of 264 ft. per min., the power consumed in hoisting this load is

$$H = 23{,}000 \times \frac{264}{33{,}000} = 184 \; hp.$$

Ques.—A mine is opened on the triple-entry system, the three main entries being driven parallel to each other. The two outside entries are free from accumulations of gas, and are driven 90 ft. ahead of the middle entry, which is found to contain explosive gas at the face. Explain how this condition could occur.

Ans.—The gas, in this case, is evidently not uniformly distributed in the seam or the underlying or overlying strata. Its appearance in the middle entry, which has progressed only to a point 90 ft. back of the two side entries, would indicate that the gas comes from a feeder or fault-line encountered by the middle entry. It frequently happens that gas will follow a slip or fault-line.

Ques.—The manometric efficiency of a mine is 70 per cent. and the mine resistance gives a water gage of 3 in. (a) If the area of the port of discharge of the fan is 0.6 of the area of the port of entry, what is the "blowing-in pressure?" (b) For the same conditions, what is the "blowing-out pressure?"

Ans.—This question is a relic of the past. In actual practice, it is impossible to measure with any degree of accuracy either the "blowing-in" or the "blowing-out" pressure of a centrifugal fan. It was formally the custom to estimate these pressures in accordance with the principle that the pressure producing circulation varies as the square of the velocity of the current, or inversely as the square of the area of the opening; in which case the pressure ratio would be equal to the square of the inverse area ratio. Denoting the blowing-in and blowing-out pressures by p_i and p_o, respectively, the corresponding relative areas being 10 and 6, in accordance with the statement of the question,

$$\frac{p_i}{p_o} = \left(\frac{6}{10}\right)^2 = \left(\frac{3}{5}\right)^2 = \frac{9}{25}$$

The mine pressure being $3 \times 5.2 = 10.4$ lb. per sq.ft. and the manometric efficiency 70 per cent., the total pressure or sum of all the pressures is $10.4 \div 0.70 = 14.857$ lb. per sq.ft. Subtracting from this the mine pressure, gives for the remaining sum of the blowing-in and blowing-out pressures $14.857 - 10.4 = 4.457$ lb. per sq.ft. But, the ratio of these two pressures being 9 : 25, the blowing-in pressure is

$$p_i = \frac{9}{9+25} \times 4.457 = \frac{9 \times 4.457}{34} = 1.18 \; lb. \; per \; sq.ft.$$

The blowing-out pressure is

$$4.457 - 1.18 = 3.277 \; lb. \; per \; sq.ft.$$

Inquiries of General Interest

Examination Questions

Coal and Coke News

Washington, D. C.

Attorney General McReynolds has filed his long-expected suit against the Lehigh Valley R.R. Co. on the ground that it is the principal factor in the combination alleged to control the anthracite output of the Pennsylvania mines. More than a dozen corporations and individuals are included as defendants and as being parties to a conspiracy to monopolize trade. The charges are the same as are already familiar in connection with the litigation in the past. It is pointed out in the bill that, through the alleged monopoly of the sale of coal produced along its line, the Lehigh Valley dominates the market at all points not reached by any other railroad, and has the power to fix without the check of competition the prices at which anthracite coal is sold. It is claimed that of 11,000,000 tons of anthracite annually carried by the Lehigh more than 82% is shipped for the account of the Lehigh Coal Co., which is described as a mere adjunct or instrumentality of the railroad itself. The litigation of 1910-11 is reviewed, and subsequent developments in conection with the sales company are described. The contract between the railroad company and the sales company, it is claimed, gave the latter unreasonably low rates for mined coal, fixed prices for coal to be mined and made other concessions of the same sort. It is alleged that the sales company's profits have been enormous, regular dividends of 2½% being paid, with an extra cash dividend of 25% after twenty one months' business and an additional extra dividend paid in stock, while a large surplus over and above dividends was retained by the company.

It is further alleged that the Lehigh R.R. Co. granted rebates and undue preferences to the coal company thereby violating not only the Sherman act but the railroad legislation of the United States.

It is understood to be the intention of the government to press the suit against the Lehigh Valley as vigorously as possible with a view to getting a thorough test of the general situation as affecting combinations of this kind, so that, if necessary at an early session of Congress, it may be attempted to revise the existing Interstate Commerce Act, insofar as such action may be found to be expedient, in consequence of the position taken by the Courts in this case.

* * * * * *

Senator Walsh has introduced a bill to promote the mining of coal and other minerals on the public domain, in which he deals separately with the several items whose production it is sought to regulate. With reference to coal, the essential points in the measure are as follows:

SEC. 2. That deposits of coal or lignites belonging to the United States, exclusive of those in Alaska, may, at the election of applicants qualified to enter coal lands under existing laws and to lease mineral deposits under the provisions of this bill, be acquired from and after the passage of this Act, in accordance with the provisions of sections twenty-three hundred and forty-seven to twenty-three hundred and fifty-two, inclusive, of the United States Revised Statutes, and acts amendatory thereof or supplemental thereto, or may be leased, as hereinafter provided.

SEC. 3. That the Secretary of the Interior is authorized to lease any deposits of coal or lignite owned by the United States, outside of the Territory of Alaska, through advertisement, competitive bidding, or such other methods as he may by general regulations adopt, in blocks or tracts of forty acres each, or multiples thereof, and in such form as in the opinion of the Secretary of the Interior will permit of the most economical mining of the coal in such blocks or tracts, but in no case exceeding two thousand five hundred and sixty acres in any one block or tract, said lands to be in compact form, as nearly as may be, no tract to exceed in length two and one-half times its width.

SEC. 6 That for the privilege of mining, extracting, and disposing of the coal in the lands covered by his lease, lessee shall pay to the United States such royalties as may be specified in the lease, which shall not be less than 2 cents per ton, due and payable at the end of each month succeeding that of the shipment of the coal from the mine, and the annual rental payable at the beginning of each year, on the lands covered by such lease, at the rate of 25 cents per acre for the first year thereafter, 50 cents per acre for the second and third years, and $1 per acre for each and every year thereafter during the continuance of the lease, except that such rental paid for any one year shall be credited against the royalties as they accrue for that year. Leases shall be for indeterminate periods upon condition of continued operation of the mine or mines, except when operation shall be interrupted by strikes, the elements, or casualties not attributable to the lessee, and upon the further condition that at the end of each twenty-year period succeeding the date of the lease such readjustment of terms and conditions may be made by the Secretary of the Interior as may be authorized by law at the time of expiration of such periods.

Harrisburg, Penn.

Testimony that the Central R.R. of N. J., which for more than a decade has been controlled by the Reading system, is not, and could not be, competitive with the Philadelphia & Reading Ry., was given on Mar. 17, by John F. Auch, vice-president, in charge of traffic of the Reading, speaking for the denfense in the new "anthracite-coal trust" suit of the government. The case involves nine anthracite-coal-carrying railroads and mining companies.

The hearing was held in the directors' room of the Reading Terminal, before Charles H. Guilbert, appointed master in the case by the United States District Court.

Mr. Auch submitted elaborate statistical data to prove that the interchange traffic of the Reading Ry. and the Central R.R. of N. J. could not be in any material degree competitive. The various interchange points in New Jersey and Pennsylvania, he showed, are merely railroad crossings and not sizable communities for the traffic of which railroads might compete. Practically all the interchange freight, Mr. Auch said, originated on the Reading lines destined for some point on or beyond the Jersey Central lines, or vice versa. Mr. Auch further declared that the Reading and Central R.R. of N. J. could in no sense be regarded as competitors for traffic between Bethlehem, Penn., and New York.

Reciting the causes that led to the purchase of a majority of the Central R.R. of N. J. stock by the Reading Co., Mr. Auch said this step was taken to procure for the Reading Ry. an entrance into New York, and to prevent a chaotic condition in the railroad situation that would have resulted had the Jersey Central fallen into other hands. The result, he said, would have been to shut the Reading out of New York completely. Mr. Auch maintained that the Jersey Central and Reading lines are mutually supplementary systems, and the very opposite of competitive.

Mr. Auch under cross-examination on Mar. 20, conducted by Mr. Coudert, counsel for the government, asserted that freight rates did not control anthracite prices. Mr. Coudert referred to a letter written by George F. Baer, president of the Reading, to T. P. Fowler, president of the Ontario & Western, under date of Oct. 1, 1906, in which Mr. Baer made the statement that if freight rates were reduced the coal companies would be compelled to lower their prices.

Testimony that any attempt to introduce new railroad competition in the Schuylkill region, where the Reading is in almost complete control, would be a costly failure, was given by Theodore Voorhees, vice-president of the Reading. Mr. Voorhees asserted that, owing to the narrowness of the mountain ravines in the Schulykill region, a competing road, taking second choice of route, would cost several times as much to construct as the Reading lines, and would have much heavier operating costs and greater fixed charges.

Mr. Coudert, counsel for the government, asked Mr. Voorhees why the Reading interests once spent $2,000,000 in what he termed "an illegal conspiracy" to prevent the building of a competing line. Mr. Coudert referred to the Temple Iron matter. Counsel for the Central R.R. of N. J. pointed out the projected line was intended to tap the Wyoming field and not the Schuylkill region.

It was brought out at the hearing, through A. T. Dice, general manager of the Reading, that the railway company never made any distinction between the Reading Coal & Iron Co. and the so-called independent coal companies in handling their product.

The Reading's control of the Wilmington & Northern R.R. came in for considerable questioning on the part of counsel for the government. The government contends that the Wilmington & Northern is a competing line between Reading and Wilmington, Del., but the Reading people assert that there were physical conditions why a large tonnage could not be sent over this line and to do so would require the building of almost an entirely new line. The Reading people also assert that the grades are steep on some parts of the road and that the cost of shipping coal over the Wilmington & Northern from the anthracite-coal regions to Wilmington would be very much greater than it is by going over the Reading lines, via Philadelphia to Wilmington.

The hearing was adjourned until Mar. 31.

PENNSYLVANIA

Anthracite

Luzerne—John M. Mack, president of District 1, of the U. M. W. of A., has issued an order proclaiming Apr. 1 as a holiday in commemoration of procuring of the eight-hour day, and ordering all members to celebrate the day by remaining from work.

Scranton—Examinations for mine foremen and assistant mine foremen in the anthracite districts will be given April 15 and 16 in the various towns in the 21 districts running from Forest City to Williamstown. It is stated that more attention will be paid to the character, conduct, and education of the applicant than heretofore. All persons taking the examination will be required to show a miner's certificate.

Lykens—Mine Inspector C. Price, of the 20th Anthracite District, included in which is the large East Brookside Colliery, near Tower City, where 20 lives were lost in August by an explosion, in his annual report shows a total of 36 fatalities in that district. The production of coal, per life lost, was 67,137 tons. There were shipped to market 1,964,723 tons, and the total production was 2,416,915 tons.

Edwardsville—Operations have been suspended at the Woodward colliery, owned by the D. L. & W., in order that necessary improvements may be made to the interior workings. Many doubtless wonder why suspensions for repairs are so numerous at this colliery, but it must be remembered that the Woodward is no longer a new mining operation. In times gone by more coal was sent to this market from this one concern alone than half a dozen other collieries, and it is still one of the greatest coal producing collieries in the entire anthracite region.

Bituminous

Patton—The supply and oil house of the Pennsylvania Coal & Coke Corp. was destroyed by fire on March 19. The burning oil made a blaze that was visible on the snow for many miles around. Defective wiring is thought to have been responsible for the blame.

Lansford—The steam shovels and scraper lines operated by the Lehigh Coal & Navigation Co. for more than a year, have almost removed the huge culm bank in the very heart of this growing town. This company is making a special effort to have the bank removed by spring in order to permit the erection of a fine $200,000 high school building.

Shamokin—After being enveloped by a huge blaze of sulphur at the Buck Ridge colliery on Mar. 20, John Soplasky, a driver boy, tried to walk along the gangway to alarm miners at work. A rescuing party found him terribly burned, and he will probably die. Five men in the rear of the boy and who had heard his cry, as the flaming sulphur approached, lay on their faces and escaped being burned. They were overcome by bad air. The rescuers took them to the surface, where they were revived. The fire was extinguished the next day.

Shenandoah—As George W. Isgate, 55 years old, and John Decrish, 18 years old, employed at the Thomas Colliery (sometimes known as the Kehley Run) were warming themselves on the morning of March 20 in a shanty on top of a culm bank on the side of the Locust Mountain when the earth opened and both men and shanty were swallowed. The breach is about 60 ft. in circumference and 75 ft. deep, and apparently leads to old workings 500 ft. deep. Rescuers set to work in hope the victims were still alive, but have to work cautionusly as the earth and rock were still caving on March 22. The shanty contained a large heating stove, which caused fear of the workings catching fire.

State Mine Inspector A. B. Lamb and officials of the company are directing the rescue work. Thousands have been attracted to the scene, and an extra force of police was called to keep them away from danger.

John Drimes, employed near the shanty, when the others disappeared, saved himself by grasping a steam pipe and clinging on until help arrived.

The colliery is operated by the Madeira-Hill Company.

KENTUCKY

Whitesburg—It is reported that the new mining towns of Benham, Poorfork, Dizney and Yocum's Creek, in the Harlan County field, will receive power from the Pocket, Va., station, making it unnecessary for the several companies interested in that part of the county to erect individual power plants.

Louisville—The Louisville Property Co., through which the Louisville & Nashville Ry. and the Atlantic Coast Line R.R. control a large area of coal lands in eastern Kentucky, held its annual meeting last week, in spite of the injunction proceedings brought by I. W. Bernheim, a minority stockholder, who brought suit to compel a change in management. Milton H. Smith, president of the Louisville & Nashville, retired as president of the property company, being succeeded by W. L. Mapother, vice-president of the railroad company.

OHIO

Martin's Ferry—Fire for a time threatened the mining town of Titonsville, near here, when nine dwellings of the Russel Coal Co. were destroyed recently. Powder stored in a number of the houses hampered the firemen in fighting the flames.

Columbus—The mine operators in Ohio are coöperating with the state mine department and the new Safety Superintendent, J. M. Roan, in educating the miners in all districts to look after safety to a larger degree than formerly. Mr. Roan has held a number of meetings with miners recently in which he instructed them in safety methods. An especial effort is made to minimize accidents in the eastern Ohio district, where they have been the most numerous.

OKLAHOMA

Oklahoma City—The State of Oklahoma is planning to enter the mining business, in the hope of providing enough coal for state institutions. The state attorney-general has been asked to condemn coal depsits underlying the penitentiary farm at McAlester. It is planned by the state board of prison control to utilize convict labor in working the operation. It is estimated that in this way coal can be provided for the state institutions at less than $1 per ton, as compared to an average of $2.70, paid during the past year. The fourth Oklahoma legislature passed an act authorizing the mining of coal under the penitentiary farm, and future proceedings will be based on this measure.

KANSAS

Pittsburg—Coal miners in district No. 14 of the United Mine Workers of America will pay 20c. monthly for the benefit of the strikers in the Michigan copper zone. A vote recently was taken on the proposition and showed a big majority to be in favor of the extra assessment. District No. 14 comprises the Pittsburg, Kan., mines. Of 12,000 miners in that district, about 10,000 are working, indicating that about $2000 monthly will be raised by the assessment. The plan took effect Mar. 1.

ILLINOIS

Gillespie—The week ending Mar. 14 was a banner week of coal hoisting at the Superior Coal Co.'s mines here. The three mines produced 13,432 tons for one day, the tonnage for the mines being as follows: No. 1, 4393; No. 2, 4431, and No. 3, 4608.

Springfield—The mine of the Cora Coal Co. at Andrew, north of this city, on the C. P. & St. L. R.R., was damaged by fire a few nights ago. The loss is estimated at $8000, and is partially covered by insurance. In addition to the framework of the shafts, four coal cars, two of them loaded, were burned.

COLORADO

Trinidad—The Colorado Fuel & Iron Co. have brought suit for damages to the extent of $1,000,000 against the United Mine Workers of America; and have secured body judgment against John T. White, president; Frank J. Hayes, vice-president, and a score of others. The charge to injure the business of the corporation through a combination of mine workers, in the basis of the suit.

INDIANA

Terre Haute—The Essanbee Mines Co. has moved its headquarters from Clinton to this city.

Sullivan—The Carlisle Coal & Clay Co. has reopened its mine, after three years' idleness. It employs 40 men.

Boonville—At a labor conference in the First District of Indiana, a resolution was adopted, opposing the mining of coal in the state by the stripping process.

Terre Haute—The Indiana Bituminous Coal Operators Association, at its quarterly meeting, reëlected the following officers: Hugh Shirkie, Terre Haute, president; David Engle, Oakland City, vice-president; Phil. H. Penna, Terra Haute, secretary-treasurer. Thirty operators, representing all fields in the state, were present.

CALIFORNIA

Vallejo—After 100 tons of coal had been removed from the hold of the army collier Jupiter, it was discovered on March 18, that she had not been on fire and that no damage had been done. Spontaneous combustion had progressed far enough to start the coal smoking, but had not reached the point of ignition.

ARKANSAS

Clarksville—The Spadra Creek Coal Co.'s "Monkey Run" coal plant was destroyed recently by fire, with a loss of approximately $50,000.

CONSTRUCTION NEWS

Fairmont, W. Va.—The Fairmont Mining Machinery Co. is planning a large addition to its present plant. This addition will be built during the coming summer.

Richmond, Ky.—C. G. Bowman, banker and coal operator, has contracted with Todd & Son for the construction in Hazard, Ky., of a two-story and basement brick dwelling 80x88 ft., which will be used for storerooms and offices. It will cost $22,000.

Fayette, Mo.—The Howard County Coal Co. will install a $25,000 brick plant near their coal mine, recently known as the Russell mine. They will manufacture bricks from the fireclay, which will be produced at the same time that the coal is mined.

Big Creek, Ky.—The Big Creek Coal Co. are starting work on another new coal mining plant at head of Pond Creek, and the construction of a two-mile spur of the Pond Creek R.R. to the new plant. Mining will begin by July 1, it is expected. They will develop 1000 acres around the new plant.

Greensburg, Penn.—The S. J. Harry Co. has been awarded a contract by the Salina Coal & Clay Co., for sinking and timbering two shafts near Avonmore. The shafts will be used for mining clay and for mining the Freeport vein of coal. The coal in the vicinity is said to be of an excellent quality.

Leavenworth, Kan.—It has been announced that the owners of the Home mine which was destroyed by fire recently will start rebuilding at once. Careful estimates place the loss at $25,000, two thirds of which is covered by insurance. No harm was done to the underground operations or timbering.

Whitesburg, Ky.—The Mineral Development Co., general offices at Philadelphia, Penn., have announced the development of 500 acres of coal lands on Colly Creek near Ermine, five miles from here, and the building of a four-mile branch line of the Lexington & Eastern R.R. The work of the new development is billed to start Apr. 1.

Salina, Penn.—The Salina Coal & Clay Co., of this place, a corporation with an authorized capital stock of $175,000, has in process of erection here, one of the largest fire-brick plants in the country, which is expected to have a daily capacity of 100,000 high-grade fire-bricks. In addition to its output of fire-bricks, the company expects to ship between 700 and 800 tons of coal daily. E. A. Serrin, of Greensburg, Penn, general manager of the company, is in active charge of the work.

Balboa, C. Z.—The Isthmian Canal Commission has just awarded to the Ingersoll-Rand Co., of New York City, the contract to furnish three large direct-connected, electrically-driven air compressors, of the Duplex type, embodying the new Ingersoll-Rogler valve. The combined capacity of these units will be 10,000 cu.ft. They will be installed in the Balboa shops, where the air will be used for general repair work in the shops, and also on the new dry dock. This equipment is to form a part of the permanent canal equipment.

Logan, W. Va.—The Main Island Creek Coal Co., of which John Laing, of Charleston, W. Va., is president, recently awarded a contract to the Link-Belt Co., of Nicetown, Philadelphia, for designing and building their new tipple equipment, consisting of an entire steel tipple, including apron conveyors for bringing the coal down the hillside, shaking screens for separating it into the various sizes and picking tables and loading booms for better preparing the coal for the trade and permitting it to be loaded into railroad cars with the minimum amount of breakage. The tipple will be erected near here.

INDUSTRIAL NEWS

Cherokee, Kan.—The Hamilton Coal Co., which recently abandoned prospecting on land near here, has resumed work on the Russell farm.

Waynesburg, Penn.—T. R. Huffman and G. E. Rice recently sold to the Bixler-Ohio Coal Co., of Ohio, 500 acres of coal for $37,500, and engineers are now on the property laying out the mines.

Cross Creek, Penn.—John A. Bell, representing Pittsburgh capitalists, has given notice to farmers in this township that he will accept options on the purchase of their coal, aggregating 1220 acres. The price for the coal is said to be $125,000.

Indianapolis, Ind.—A judgment of $6625 was obtained in the Superior Court of this city, by William C. Shoemaker against the receiver for the Carbon Coal & Clay Co., for use of machinery valued at $30,000, on which the company failed to pay the rental and other charges.

Princeton, Kan.—Much interest is manifested by operators of Missouri in recent discoveries on the Vernie Boxley farm near here, where a vein 45 in. thick was struck. The coal was found at a depth of 512 ft., the vein being covered by 5 ft. of slate. A couple of feet of fireclay underlies the coal. Drilling also is being done on the Kesteron and Mason farms, near Princeton.

Joplin, Mo.—The American Concentrator Co., of this city, are moving their entire business to Springfield, Ohio, where they will be permanently located in future. The new location will provide very much better facilities for the manufacture of their products, and it is the intention of the company to erect immediately an up-to-date testing plant for handling coal and ores of every description.

East Liverpool, Ohio—The Rhea mine at West Point, near East Liverpool, has been bought by the Kirk-Dunn Coal Co. The main office will be at Salem, Ohio. Many changes and improvements are being made. A new tipple is being constructed and the mine will be operated electrically. This company has recently acquired over 3000 acres of coal land under which lies a 5-ft. vein of fuel.

Birmingham, Ala.—The Government is now making an exhaustive test of Alabama coals at the ports of Mobile and Pensacola, for use on war vessels, etc., and the reports are that the coal has been found to be equal to the majority of the West Virginia and Pennsylvania coals, which they have been using. It is expected that this test will result in the Government placing contracts for Alabama coal for use through these ports.

Calgary, Alta.—Sir Donald Mann, vice-president of the Canadian Northern Ry., states that by opening up a new line making connection with the Brazean coal fields of Alberta, about 250 miles north of the Crows Nest fields, the railway will be enabled to secure its coal supply at a dollar per ton less than other roads. The direct connection established between the mines and the cities of Edmonton and Calgary will reduce the cost of coal at those points to one-half of present prices.

Montreal, Que.—H. A. Lovett, of Montreal, president of the Canadian Coal & Coke Co., which last year acquired the properties of the Letlebridge Collieries, Ltd., Western Coal & Coke Co.. Ltd., Pacific Coal Fields, Ltd., and St. Albert Collieries, Ltd., announces that for the purpose of permanent financing the company has authorized the issue of $3,000,000 par value of bonds, and for temporary financing has authorized the issue of $1,500,000 of short-term securities, for which the bonds are pledged as collateral.

Louisville, Ky.—Roy Wilhoit, president of the bankrupt Wilhoit Coal Co., has purchased the assets of the company, including about 2000 acres of valuable coal land on Ewing's Creek, in the Harlan County field, for $31,000. Mr. Wilhoit states that he will handle the properties at present through Roy Wilhoit & Co., which have been organized for that purpose, with the view of leasing two of the three seams on it for operation, the other being now under lease to the Walkins Creek Coal Co., which is operating it.

PERSONALS

Alfred W. Calloway was recently elected president of the Davis Coal & Coke Co., of New York City, in place of J. M. Fitzgerald, resigned.

Albert E. Oliver, formerly superintendent of the National Fuel Co., at Bowen, Colo., has resigned to take charge of the Huerfano Coal Co., Walsenburg, Colo.

L. W. Robinson, of Punxsuatawney, Penn., president of the Rochester & Pittsburgh Coal & Iron Co., has purchased the estate of the late Joseph Jefferson on Jupiter Island, in Florida.

Edgar Connell, superintendent for the last five years of the Enterprise colliery, at Shamokin, Penn., operated by W. L. Connell, of Scranton, resigned on March 18, to enter the retail coal business. He will be succeeded by Alfred Hall, of Scranton.

H. F. Miller, who for the past year has been associated with the advertising department of the Otis Elevator Co., and for four years previous to that, with the Western Electric Co., has been appointed advertising manager of the Goulds Manufacturing Co., of Seneca Falls, New York.

Edward H. Coxe, of LaFollette, Tenn., has resigned as general manager of operations for Neil Robinson, receiver of the LaFollette Coal, Iron & Ry. Co., to take effect May 1. Mr. Coxe will be succeeded by George M. Shoemaker, now superintendent of the Rex No. 1 mine for the receiver. J. M. Page, who was for some months superintendent of Rex No. 2 mine, recently suspended, will succeed Mr. Shoemaker as superintendent of Rex No. 1 mine.

J. B. Nessel has been appointed general freight agent of the Pittsburgh & Lake Erie R.R., to fill the vacancy occasioned by the promotion of W. A. Newton, to a similar position with the New York Central & Hudson River R.R. Mr Nessel was an incumbent of the office some two years ago, at which time he was transferred to Cleveland as general coal, coke and ore agent. His re-appointment is especially gratifying to the Pittsburgh district people.

W. L. Morgan, formerly state mine inspector, eighth district, East St. Louis, Ill., was appointed instructor in the Miners' and Mechanics' Institute, by Dr. James, president of the University of Illinois. The appointment was approved by the board of trustees of the University Feb. 16, 1914. The law authorizing the formation of the Miners' and Mechanics' Institute was the act of the 47th assembly, but it was left for the next legislature to provide the means for carrying this law into effect.

OBITUARY

Fred F. Lange, one of the best known mining engineers in the Oklahoma coal field, was found dead in his office at McAlester, Okla., on Mar. 20. His lips were burned with carbolic acid, and a party-filled bottle of the same drug was found beside the body. Mr. Lange formerly was in the employ of the government. At the time of his death, he was in the segregated land office at McAlester.

William C. Bullitt, died early on Sunday morning March 22, at his home in Philadelphia. Prominent for many years as a leader in reform movements, he was one of Philadelphia's best-known citizens. He was a member of the firm of Casther, Curran & Bullitt, large domestic and export coal shippers and mine owners.

Mr. Bullitt was the son of the late John C. Bullitt, one of the leaders of the Philadelphia bar, who is best remembered as president of the commission which drafted the Bullitt law, creating the present city charter of Philadelphia. The son was born on June 18, 1856, on his father's country place in Chestnut Hill. William C. Bullitt received his primary education in Dr. J. W. Faire's classical school and then entered the University of Pennsylvania, from which he graduated in 1876. He studied law at the University of Virginia and later in his father's office.

From 1885 to 1909 Mr. Bullitt was closely identified with the executive department of the Norfolk & Western R.R. His first connection with that corporation was as assistant to the president. Subsequently he was elected a vice-president. He became an authority on constitutional law, and entered other fields, ending with the coal operating firm in which he was a partner at the time of his death. The concern has extensive mining operations in the Pocahontas coal field in West Virginia.

Mr. Bullitt's clubs were the Philadelphia, Rittenhouse, Philadelphia Country, City, Southern, St. Anthony, and University, of New York. He is survived by his widow and three sons.

NEW INCORPORATIONS

Johnstown, Penn.—The Conemaugh Smokeless Coal Co. has been incorporated here with a capital of $500,000.

Carlisle, Ind.—The Chicago-Carlisle Coal Co. has been incorporated here, with $100,000 capital stock, to operate coal mines. The directors are George A. Van Dyke, Webster A. Patterson and Robert J. Frank, all of Chicago.

Bloomington, Ind.—The McDaniel-Freese Coal Co. has been incorporated here, with $15,000 capital stock, to deal in fuel. The directors are Simeon C. Freese, A. Freese and Lucian C. McDaniel.

Dover, Del.—Articles of incorporation were filed here at the State Department for the Columbia Coal Co., capital $5,000,000. The objects are to acquire oil, coal and mineral lands in all parts of the United States, especially in Western Pennsylvania and Ohio. The incorporators include W. M. Pile, George C. Steegler and Lawrence W. McCarthy.

Allbright, W. Va.—The Cheat River Coal Co. has been organized here to mine and market coal and other minerals. The capital stock is $500,000, of which $50,000 has been subscribed and paid. J. Clyde Markley, A. R. Falcom, S. T. Seale, J. W. Menesee and R. W. Mason, all of Allbright, are incorporators

Birmingham, Ala.—The Canal Export Coal Co. has been organized with a capital stock of $300,000, of which $165,000 has been paid in. The new company will engage in coal mining, selling and exporting on a large scale. R. H. Elliott, of Birmingham, is president; E. P. Kimbrough, of Greensboro, vice-president; W. C. Lovejoy, of Montgomery, secretary; and R. B. Evins, of Greensboro, general council. The main offices of the company will be located in Birmingham.

New Link-Belt Data Book on Silent Chain Drives

For the first time in history, an Engineering Data Book has been published by a manufacturing concern, which will enable users of power to select the correct Silent-Chain Drives for their work and determine exact costs from list prices shown in the book. Besides giving complete Engineering Information on Silent-Chain Driving in simple and compact form, Data Book No. 125 describes many uses of Silent Chain for the efficient transmission of power and gives specific reasons and illustrations showing application in a large variety of uses. Link-Belt Silent Chain is a series of links connected by joints which consist of segmental case-hardened bushings and case-hardened steel pins. The chain is as flexible as a leather belt—as positive as a gear. Its rated efficiency is 98.2 per cent. on actual test. It will transmit any amount of power quietly. Over 200,000 installations, we understand, were drawn upon for the information contained in this data book. The book is the only work of its kind and consists of 112 pages, bound in flexible red cover. Copies can be obtained free of charge by addressing the manufacturers, Link-Belt Co., 39th St. and Stewart Ave., Chicago.

Coal Trade Reviews

General Review

Spring business in anthracite opening up buoyantly, with numerous orders from all points. Some last-minute buying in bituminous, but consumers mostly show a discouraging lack of interest in the impending suspension. Railroads beginning to accept consignments in the Lake trade.

The coal year is closing with current business in anthracite at a complete standstill but a marked activity on negotiations for the new year. As usual, the individual operators initiated selling at the April cricular about the middle of this month, but the big companies have consistently maintained the regular winter schedule, although most of the loading during the past week has been for April delivery at the spring prices. The line trade is also active on the new business. The unexpectedly long duration of cold weather has served to clean up stocks in an unusual manner, and a heavy trade is anticipated through April and May.

On the eve of what appears to be a certain suspension in the principal bituminous coal districts of the country, the market continues relatively dull and listless. Some last-minute business has developed, causing a slight stiffening in prices, but, on the whole, the trade is far from what would normally be expected at this time. In the Pittsburgh district, occasional shading of prices is noted, though the large companies are demanding premiums and the nominal market continues at the regular circular. There is little confidence in the possibility of a long suspension and consumers seem to be well stocked for any emergency that may arise.

In Ohio, consumers, as a rule, refuse to be influenced by the possibility of a suspension, while the warm weather has caused a lull in the domestic business and dealers are endeavoring to clean up stocks rather than accumulate supplies. The railroads are beginning to accept lake coal, which may relieve the pressure; contracts in this line are being negotiated on the same basis as last year, but subject to any change in the wage scale.

The spot demand at Hampton Roads is light, the movement being confined almost entirely to contract; other West Virginia coals are dull and heavy, in spite of the near approach of the lake shipping season. The eastern Kentucky district, which will not be involved in the labor controversy, is anticipating a heavy business in the event of a suspension. The feature of the Southern market at the moment is a sharp decline in the prices of fuel oil, which may seriously affect the coal business.

The general indifference of consumers to the possibility of a serious strike has created a great deal of uncertainty in the Middle Western markets. There has been some stocking, particularly on the part of the railroads, which has developed a hardening tendency in the market, but this is not by any means of notable proportions. Contracts for the new coal year are being signed without any provision for increased cost of production.

EASTERN MARKET

BOSTON

Pocahontas and New River extremely dull but less anxiety over prices. No change in Pennsylvania grades, although a fair movement all-rail, due in part to possibility of suspension. Anthracite stocks fast running down and a good trade prospect for April. Stove shortage looks serious.

Bituminous—The situation on the Hampton Roads coals is practically at a standstill. There is ample supply at the loading piers and bottoms are despatched in record time. The few buyers here that are interested in making early purchases are now all cared for, and those who preferred to postpone are refusing to be hurried. A slower or duller period has not been experienced in this market since the summer of 1912. The price level has not been modified, however, and all hands seem content to await developments. On the whole there is rather less anxiety over price-shading than a week or two ago, and that is a hopeful sign. The producing interests are about agreed that nothing is to be gained by forcing coal on a reluctant and hesitating market.

The supplies of spot fuel at the distributing points are small and with only a moderate inquiry. The continued cold weather has given the trade a slight impetus but the outlook is hardly encouraging.

Aside from requisitions for shipment in conjunction with anthracite from Philadelphia the demand for the Pennsylvania grades is without special change. There is only a scattering business and then only for the most popular coals. All-rail the movement is fair, considering general conditions, and prices are showing up rather strong. The possibility of a suspension Apr. 1 is an element in that territory particularly but what uneasiness there is exists only in mild form at the present writing.

Anthracite—Stocks that were kept light in anticipation of warm weather and early April shipments have been fast depleted the past two weeks and the prolonged winter has had dealers guessing. They are running borrow and loan accounts with one another on the various domestic sizes and the trade is in excellent shape for the beginning of the new season.

The problem of getting a sufficient supply of stove is a serious one with practically all the dealers. The shipping companies are firm in declining orders that do not include a fair amount of other sizes.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.90	2.92@3.02	
New York*	2.50@3.05	2.80@3.20	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.85
Boston†				3.73@3.83
Providence†				3.68@3.78

*F.o.b. †On cars.

NEW YORK

Considerable activity in anthracite at the spring circular. Prepared grades generally easy but all the steam sizes short. Bituminous at a standstill pending the conclusion of the labor conferences. Demand light.

Anthracite—The close of the coal year finds practically all of the business being negotiated at the opening circular. This has been the market with individuals since Mar. 20, and, although the companies are nominally maintaining their winter circular, there is no business being negotiated on this basis. Loading at the tidewater piers is entirely at the April figures, but deliveries will not be made before that time. The line trade is also good on April business, and the indications point to an active business through April and May, due to the unexpected duration of low temperatures.

In the prepared grades, stove is quite short with some, but long with others, while chestnut is short all along the line, egg in good demand, with a fair supply, and pea the same The high-grade buckwheats are scarce, even at premium prices, while the low grades are also short. The better qualities of rice are practically out of the market entirely, and the off grades difficult to obtain at premium prices. The high grades of barley are equally as scarce as rice, but the others are in fair supply at normal prices. We quote the New York hard-coal market on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$5.00		$5.05	
Egg	5.25	$4.85@5.35	5.30	$4.80@5.30
Stove	5.25	4.85@5.35	5.30	4.80@5.30
Chestnut	5.50	5.10@5.55	5.55	5.05@5.50
Pea	3.50	3.55@3.65	3.50	3.50@3.60
Buckwheat	2.75	2.75@3.00	2.70@3.45	2.60@2.90
Rice	2.25	2.25@2.35	1.95@2.20	2.00@2.30
Barley	1.75	1.75@1.85	1.70	1.60@1.80

Bituminous—The uncertainty in the labor situation has brought the local market to a complete standstill. There appears to be little stocking, and the agencies are in doubt about accepting what orders do come in, because of possible difficulties in filling them. A slightly increased demand is noted, due, in part, to anxiety over the labor situation and also to the colder weather. Considerable lake coal is reported sold in West Virginia and slack continues stiff in the Fairmont region. Local buyers are showing a desire to close contracts at last year's figures, or better, where these represent the lower opening scale. Eastern consumers are content to hold off, pending further developments.

The car supply on the Baltimore & Ohio R.R. have been deficient, which has withheld considerable tonnage. Mines are reported to be working under increased production. We continue last week's quotations which are probably a little stiffer, as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; George's Creek, $3.15@3.25.

PHILADELPHIA

Anthracite quiet, with the exception of steam sizes, which continue in good demand. Better tone to bituminous, indicated by increased tonnage, and slightly better prices.

Anthracite—Outside of a slightly increased demand for coal at retail, caused by the lower temperatures of last week, the domestic market is simply marking time, awaiting the opening of the spring business. Pea, buckwheat and rice, however, not being effected by the discount, still continue in good demand, and while the market lasts, the operators are producing and lifting from stock every ton possible. The advent of mild weather is likely to cause a decided falling off in the call for these latter sizes, as they are largely used for the generation of heat in the large office buildings and apartment houses.

The first of next week will see the opening of the season of 1914 and 1915 and indications point to an active demand for at least two or three months. The unusual weather conditions during March has reduced dealer's stocks, to such an extent that they will go into the month with little or no coal. It is understood that there will be no change whatever in the circular prices with the exception that the state tax will apply on all sizes.

It has not been a particularly successful year for the retail dealers in this locality. The open weather prevailing until March, when one snow storm followed another, making deliveries expensive and rapidly wiping out any profits made earlier in the year, caused the season to be a poor one. The fact that dealers were able to dispose of practically all of their stocks, is about the only bright spot in the situation; it is the exception that Apr. 1 finds the dealers with cleaned up yards.

Bituminous—Slightly better conditions mark the situation in bituminous trade, as indicated by heavier production, and higher prices. This may or may not be due to the possibility of trouble on the first of April, but it is fact that there is a disposition on the part of large users to take on a surplus. Quotations are from five to ten cents better than last week, and with the car movement again normal, deliveries are fairly prompt.

BALTIMORE

Poor transportation stiffening up the soft coal trade but gas-coal market still weak. Continued cold weather helps the anthracite business.

With nearly all the Pennsylvania operators complaining that they cannot get enough cars to move the coal as desired, a stiffening of the market has developed. Inquiry showed that little or no Pennsylvania steam coals were offering at the mines for quick delivery at below 95c. and $1, while the better grade fuels were easily commanding from $1.15 to $1.35.

The weakest feature of the market just now is the West Virginia gas coals. Even the approach of the lake season does not seem to help the situation. Three-quarter is freely offering at 85c., and even less at times. Slack, as a result of a sharp demand from the cement industry, is showing renewed strength. West Virginia steam coals are selling at about 90 to 95c. at the mines.

Considerable coal has been loaded at the piers recently, the railroads having been able to clean up all the surplus that accumulated due to their inability to rapidly discharge frozen cars. A number of large shipments are being made the present week on foreign account. The coastwise shipping remains rather dull, except for the movement in company-owned collieries, principally to New England ports.

More snow at the outset of the present week, with a temperature at times below the twenty mark, boosted the retail anthracite trade. The present winter, while mild at the outset, has been much longer drawn out than for a number of seasons past.

CENTRAL STATES

PITTSBURGH, PENN.

No prospect of scale settlement at Chicago conference, and suspension in prospect. Slightly improved demand due wholly to this prospect, but prices merely maintained at circular level. One coke contract at an advanced figure but general market quotable unchanged.

Bituminous—The Interstate Joint Conference, in session at Chicago since Tuesday, Mar. 17, has reached no agreement on a wage scale for two years or four years from Apr. 1, and is not at all likely to reach any. Reports are in the circumstances more or less untrustworthy. One is to the effect that the miners are willing to renounce the mine-run demand if the check-off is continued.

Demand for coal has slightly increased, and mines are operating still better, probably at an average of fully 80%, taking the Pittsburgh district as a whole. Prices have stiffened only a trifle, being held down by competition from other districts, which are willing to absorb some freight disadvantage in order to market their coal. Whatever increase there has been in demand for coal since the first of the month is purely in anticipation of a mining suspension, as domestic trade has become slack again and there is no increase in consumption by manufacturers.

There is occasional slight shading of regular prices, while one or two large interests are willing to sell free coal only at a premium of 10c., but in general the market is quotable at the regular list: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—One contract for furnace coke at $2.10 has just been put through, covering 10,000 tons a month for the second quarter, but the circumstances are such that the market is not squarely advanced to that level, since the sale was to a merchant firm who will apply the coke on contracts with customers requiring a strictly first grade. Prompt coke is in very poor demand and the market easy in consequence. The market continues quotable as follows: Prompt furnace, $1.90@2; contract furnace, $2@2.10; prompt foundry, $2.40@2.60; contract foundry, $2.40@2.60, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connnellsville region in the week ending Mar. 14 at 353,405 tons, an increase of 7715 tons, and shipments at 377,045 tons, a decrease of 6797 tons.

BUFFALO

Generally heavy bituminous stocks and market dull, with no further stir anticipated. Anthracite season closed and consumers all want April delivery. Coke unchanged.

Bituminous—There is a general disposition to consider the coal season closed, so far as bituminous sizes are concerned. Consumers have stocked up considerably of late and seem to feel safe, no matter what happens. In many cases they are quite unable to carry any more, as storage capacity is all taken up. This does not indicate that the trade has been satisfactory, for the margin of profit has been small at best and considerable coal has been sold after accumulating more or less car service. This is always the case when the prices drop off, for the miners never seem to learn that consignment business is disastrous. There is not much unsold coal in transit now.

That the coal men are uncertain as to the future of the trade is shown by the few bids on public-supply contracts. There is sometimes only a single bid and on the city waterworks tender there were only three, though this is the one usually most contested. The lowest bid this year was by the Valley Camp Coal Co. of Cleveland, $2.07 for 35,000 tons of slack on a 13,500 B.t.u. test. The company is not represented here.

There is less confidence than formerly in the proposed suspension of mining because of the fact that the operators will not hold together.

The quotations of bituminous continue fairly steady on the basis of $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.25 for slack, with Allegheny Valley about 25c. less. There is a market for all the slack offering.

Coke—There is no stir in coke. Prices are steady, but only on the supposition that they have reached the bottom. The plan is to cut down production to meet the situation and wait for developments. Prices are still based on $4.50 for Connellsville foundry.

Anthracite—Practically all orders for anthracite are now

for April delivery. The local trade has run down very fast of late. There has been four lake cargoes added to the fourteen loaded sometime ago, which will end that branch of the business till the lake season opens. Some of the anthracite companies have so much of the large sizes left over that they do not know just how to turn and do not like to load anything but the smaller sizes into vessels now. Recent furnace construction is said to favor the smaller sizes even more than formerly.

TOLEDO

Market in a waiting attitude. The steam output small, considering conditions. No demand for domestics.

With seasonably fair weather now, local dealers are awaiting the outcome of the operators and miners conference. In previous years large consumers were always accustomed to anticipate a possible strike but purchasing agents have as a rule, failed to consider present conditions as serious and have engaged little storage stocks. The reserve supplies in and about Toledo, are unusually small.

The domestic grades are quiet. There are a few small orders, track coal being in more ready demand. The local market is waiting future developments. Transportation matters are in excellent shape and the opening of the new Pennsylvania bridge will facilitate traffic.

Prices are holding to the following:

	Pocahontas	Hocking	Jackson	Pomeroy	Massillon	Pittsburgh	Cambridge
Domestic lump..	$2.25	$1.25	$2.50	$1.75	$2.50	$1.40	$1.40
Egg.....	2.25	1.25	2.50	1.50	2.50	....	....
Nut.....	1.75	0.80	2.00	1.75	2.50	1.35	1.20
¾ lump.....	....	0.90	....	....	....	1.20	1.20
Mine-run.....	1.40	1.15	....	....	....	1.10	....
Slack.....	....	0.70	....	....	....	....	....

COLUMBUS

On the eve of a suspension the trade is quiet and dull. The price list off and there is little demand for stocking. Domestic business about over for the season. Most of the trade playing a waiting game.

The coal trade in Ohio is quiet and there is little to indicate the coming suspension which is believed to be inevtable. Stockng on the part of steam users is not active and the domestic demand is about over. On the whole operators as well as jobbers are playing a waiting game and are not inclined to figure ahead.

The warm weather has caused a lull in domestic demand, which was the life of the trade during the latter part of February. Dealers have been trying to clean up their stocks and consequently they have been careful in their orders as they are loath to enter into the summer season with large stocks. What few domestic orders received are for small quantities and for immediate shipment.

Steam users are either depending on West Virginia coal, or have prepared for a short suspension. Many of them have stocks to last for 30 to 45 days, which is expected to be the length of the suspension. Jobbers say that consumers refused to be influenced by talk of a suspension as on former occasions. Railroads have stocked up heavily and most of the larger lines have supplies to last for about two months.

As a result of the lull, operations have not been active during the past week. The Pomeroy Bend district reports almost full time and about 90% of the average. In the Hocking Valley the output has been about 65% and the same in the smaller fields. In eastern Ohio some of the companies report about 75 to 85%, while others say that 50% is the average. During the remainder of the month operations are not expected to be active.

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump.....	$1.45 @ 1.35	.....	$1.50 @ 1.40	$1.40 @ 1.35
¾ inch.....	1.30 @ 1.25	$1.20 @ 1.15	1.35 @ 1.30	1.30 @ 1.25
Nut.....	1.25 @ 1.20	.....	1.30 @ 1.25	1.25 @ 1.20
Mine-run.....	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack..	0.80 @ 0.75	.....	0.90 @ 0.85	0.75 @ 0.70
Coarse slack.....	0.70 @ 0.65	0.95 @ 0.90	0.80 @ 0.75	0.65 @ 0.60

CLEVELAND

Two days of raw cold weather created a good retail business. But succeeding warm weather and the surplus coal on track has kept prices low and the market dull. Lake shipments started last week.

The marked dullness of the local market was in no wise improved last week. Operators and jobbers all had more coal on track than they could move. Concessions as large as 10c. below cost were reported on coal in car service and with this competition to meet some remarkably low prices were quoted.

The heaviness centered particularly around fine coal. No. 8, Middle district, Youghiogheny and Fairmount grades were freely offered on a competitive basis. Almost hourly telephone communication was held with those attending the joint conference at Chicago, developments being hoped for that would furnish a foundation for higher prices; in other words a sine die adjournment or assurance of no agreement. When it became evident that the conferences would be carried into the present week, no attempt was made to hold the market. Where possible orders were canceled or postponed and attempts made to trade coal en route for that to be shipped this week, but the wholesale trade was too well supplied to relieve the market in this way.

The railroads began accepting lake coal the middle of the week and this may relieve the pressure somewhat. Lake shippers canvassed the vessel market for boats to load before May 1, but found little boat capacity available. Most of them were loaded last fall and those made ready during the winter were promised some time ago. Considerable lake coal will be loaded if the market remains at the present low level. The railroads are loading their own equipment with this coal and charge no car service until May 1. Those who are not lake shippers are barred from taking advantage of this service as the railroads will reconsign to local trade only upon the payment of all-rail rates and car service on regular local shipment basis.

The attempt to break the freight rate from Lake Erie to Lake Superior to 25c. apparently has been abandoned and 27½c. is being offered. Shippers generally are holding back contracting until the Chicago conference is over. Some lake coal has been negotiated subject to any change in the wage contract but the business is not brisk because of large stocks at the upper lake docks.

Prices at which spot coal and coal en route were sold last week were as follows:

	Pocahontas	No. 8	Middle District	Fairmount	Youghiogheny
Lump, ¾ in.	$3.10	$1.85@1.90	$1.85@1.90	$1.90	$2.35
Egg.....	3.10				
Mine-run..	2.75	1.85@1.90	1.85		2.25
Nut.....		1.95	1.95		2.20
Slack.....		1.80	1.75	1.85	1.90

DETROIT

Active opening business anticipated. Many orders already on hand. A 30-day suspension would do much to help the market.

Bituminous—While the steam grades are showing a tendency to drag, indications point to an active opening on the domestic fuels. Irrespective of whether a suspension occurs on Apr. 1, the numerous orders already coming in for April delivery are sufficient to assure an active business. It is hoped, however, that there will be a suspension in mining of about 30 days' duration, as this would help to clean up stocks and put the business on a firmer basis. As yet, there has been no change in the price level, and slack coal continues to be the leader in spite of heavy shipments.

Coke—The local coal market is decidedly stiffer, with orders accumulating far beyond expectations. Semet Solvay is quoted at $3.25 on contract, with Connellsville foundry, 72-hr., $2.75 and gas house at $2.75 f.o.b. ovens.

HAMPTON ROADS

Dumpings for the week fair. Demand still light on all grades. Largest single cargo of the week goes to Brazil.

The movement of coal from Hampton Roads piers during the week has been only fair. During the early part indications were that dumpings would be extra heavy, but toward the end vessel tonnage fell off and shipments have not come up to expectations. A few large shipments have been made coastwise and to the foreign trade. The largest percentage of this as usual, went to the New England market although there was some movement to one or two of the Southern ports. Of the export business the largest single shipment went to Venice, this amounting to approximately ten thousand tons. Demand all week has been light for spot coal and so far as can be ascertained practically all that moving has been on contracts.

Export shipments for the week have gone to Rio de Janeiro, Laplata, Bermuda, Vera Cruz, Curacoa, Naples, Canal Zone, St. Thomas and Havana. There has been some movement of high volatile coal in addition to the New River and Pocahontas run-of-mine. Prices on all grades remain practically the same as they have been for several weeks.

LOUISVILLE, KY.

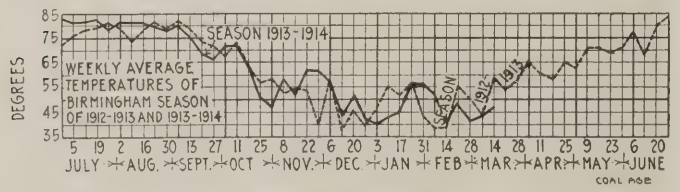
Moderately severe weather has continued, enabling the retailers to clean up stocks. Little new demand as buying is hand-to-mouth in all quarters. Prices steady at the low levels prevailing recently.

Following several days of mild weather, there was another snow-storm on Thursday resulting in renewed orders for the retailers, few of whom had any difficulty in filling them. Few of them were forced into the market, the reluctance to buy

any more coal than absolutely necessary to fill immediate needs not being confined to domestic consumers, by any means.

The absence of any stocking demand is one of the remarkable features of the present situation, especially in view of the continued talk of a strike next month. If there is labor trouble in any of the fields, it is certain that the Eastern Kentucky mines, not being involved, will have all they can do in supplying the demand from other quarters. In this case it is apparent that regular customers may find it difficult to secure coal, which should result in a heavy demand for summer stocks by the retailers.

In view of the slack demand, prices remain at the same low level as for some weeks past, $1.50 for first-class block being about the limit. Generally speaking, there is ample nut and slack to satisfy the steam market, in spite of the short production of the domestic grades, and prices are only moderate on this and other steam grades, 85c. being about the top, with a light demand.



SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM

Domestic lump moving, but steam coal quiet. Practically no market for either furnace or foundry coke. Only a small tonnage of pig iron sold, but at prices in advance of $11 2 F., f.o.b. Birmingham. Car situation satisfactory.

The severe cold weather of the past ten days has brought out orders for rush shipments of lump coal, and the majority of the operators claim to have had the best business in that line for several months. However, as the steam-coal market is quiet, some orders for lump were refused, there being no way to dispose of the screenings. The demand for steam coal is small, at the present time, many of the mines running only two and three days a week, but it is thought that conditions will shortly improve. Blacksmith coal is normal, both as to tonnage and price.

Furnace and foundry coke are dull, but, as the railroads have reduced the rate $1 per ton to Western points after having raised them $2 per ton on Jan. 1, the Birmingham manufacturers are again preparing to go after this business. The reduction makes it possible to again put Alabama coke in the Western territory. Furnaces report only a small tonnage of pig iron sold, but the prices have advanced and are well over the $11 mark for 2 Foundry f.o.b. Birmingham for the first half of 1914. The car situation is satisfactory.

NEW ORLEANS

Cut in price of fuel oil from Mexico affects the coal market. Prices unchanged but tendency is to soften. Stocking for discount season to begin next month. Rise in Alabama rivers increases movement.

Mexican crude sold at 35c. a barrel less than has been paid during the last year. As yet there has been no further concession made by coal dealers since the reduction of six weeks ago but in the face of the marked decrease in oil it is feared that the advantage which has been gained during the past year, will be lost. With several weeks of uninterrupted cold weather, followed by a brief mild spell and another cold wave, stocks have been reduced in the local yards to nearly a normal level, and there will be little tonnage carried over. Stocking on a smaller scale will begin next month.

In order to take advantage of high water in the Warrior River, the New Orleans & Alabama Transportation Co. has taken its power barges out of the merchandise trade and will concentrate its efforts in bringing down as great an amount of coal as possible during the season of high water, which is likely to continue until June. As yet the company has not secured sufficient coal to become a factor in the market although it continues to make contracts at fifty cents a ton lower than the companies handling up-river coal or those dealing in Alabama all-rail product.

INDIANAPOLIS

Mines busy supplying a heavy storage demand from large consumers. Railroads giving better car service. Prices hold stiff on all grades. Retail quotations unchanged.

There is not much change in local conditions. The weather kept seasonably cool until the season officially ended Mar. 20 and the car service has improved temporarily, at least so that most mines in the state have been running full time. The storing of coal against the possibility of a shut-down resulting in a steady run of orders. Little has transpired to indicate that there will be suspension, but large coal users have learned to be forehanded.

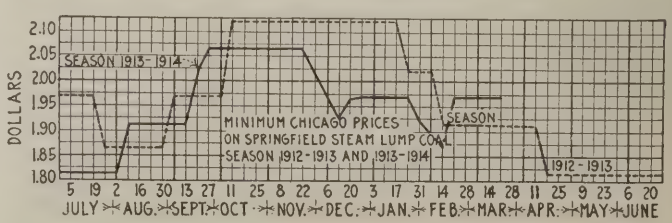
The domestic trade averages up well, although purchases are mostly for stocking-up and will be largely limited to that until the end of the season. Screenings and other steam grades continue in good demand at prices well up the maximum of the winter. The railroads have been among the large purchasers and there is less likelihood of their confiscating coal, as in former years, in case work is suspended at the mines. Retailers in this city are still selling at the prices set Sept. 20. It is doubtful if there has been a former year when prices were so uniform throughout fall and winter.

ST. LOUIS

Lack of interest among buyers the feature of the present situation. Little surplus buying except among larger consumers. Basis of new contracts not providing for increase in cost of production.

The passive attitude of the coal-buying public previous to a strike period is one of the greatest surprises that the trade has had in many years. During the past week there has been several purchases of storage coal made, but not to the extent that was anticipated, and not anywhere near the volume in past years under the same conditions. Several railroads have been buying for the past two or three weeks, but only in small quantities, though increasing during the past ten days. At most steam plants there is little storage coal in sight, with the exception of those in the lead belt, and two or three large manufacturing plants on the east side. The coal buyers seem to think that even should there be a shutdown, it will only be for a short time, and when the mines resume again, the operators will be just as eager for business as now, and prices will be on a correspondingly low level as usual.

Until the beginning of the present week, it has been a summer market, as far as prices have been concerned, but this is only on the larger sizes, screenings being lower than at any time last summer. With the beginning of the present week there has been a change, but even at the best, prices will not be anything like they were at the last suspension. No increased cost of production is anticipated for the coming year, as far as the Illinois fields are concerned, and some operators and shippers are already in the market with contracts, for both one and two years.



During the past week something like 250 to 300 cars of anthracite have been sold for April shipment, and about the same amount for May and June. Some smokeless has been bought for April delivery, and some also for May and June, but not the tonnage that was expected.

There is absolutely nothing doing in coke, gas house and byproduct being a drug on the market, and the future is somewhat uncertain for fuel of this character.

The circular market at the close of the past week was as follows:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump				$0.90 @ 1.00	$1.15
3-in. lump			$1.50		
6-in. lump	$1.35 @ 1.50		1.30	1.15 @ 1.25	1.35
Lump and egg	1.85 @ 2.15	2.25			1.15
No. 1 nut	1.30 @ 1.45				
Screenings	0.75 @ 0.85			0.65 @ 0.70	0.75 @ 0.80
Mine-run	1.10 @ 1.20			0.80 @ 0.85	
No. 1 washed nut	1.50 @ 1.60	2.25	1.50		
No. 2 washed nut	1.25 @ 1.35		1.25		
No. 3 washed nut	1.25 @ 1.30				
No. 4 washed nut	1.25 @ 1.30				
No. 5 washed nut	0.80 @ 0.85				

The April anthracite circular, f.o.b. St. Louis, will be: Chestnut, $7.05; egg and stove, $6.80; grate, $6.55. The smokeless circular for April will be: Lump and egg, $4.35; mine-run, $4. On Arkansas anthracite, the April circular will be: Lump, $5.25; egg and chestnut, $5.50; pea, $4.50.

KANSAS CITY

Operations much curtailed but prices steady at a low level. Little new business anticipated.

Despite more favorable weather conditions, operations in Kansas and Missouri are still limited to about 50% of total capacity. Quotations have remained steady at the rock bottom prices which have prevailed for several months past. The last of March made a desperate effort to retrieve the results of the early part of the month, with only fair success. Consumers anticipating warmer weather have refused to order and the same is true of retailers, who are clinging to the old hand-to-mouth basis.

FOREIGN MARKETS

GREAT BRITAIN

Mar. 13—As a result of stormy weather, tonnage is being delayed and stocks of coal are excessive. In the circumstances it is an easy matter to secure concessions for prompt supplies, but colliery owners regarding this adverse state of affairs as only temporary, are holding with firmness for late March positions. Quotations are approximately as follows:

Best Welsh steam	$4.50	Best Monmouthshires	$4.11
Best seconds	4.38	Seconds	3.93
Seconds	4.14	Best Cardiff smalls	2.64
Best dry coals	4.26	Seconds	2.52

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are net f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days.

PRODUCTION AND TRANSPORTATION STATISTICS

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic from the New River, Kanawha and Kentucky districts for January and the seven months ending Jan. 31, 1912 and 13, in short tons:

	January				Seven Months			
Destination	1914	%	1913	%	1914	%	1913	%
Tidewater	408,994	25	377,520	30	2,023,497	19	2,068,111	22
East	300,426	18	303,493	24	1,555,035	14	1,518,698	16
West	887,284	54	489,985	39	6,568,361	61	5,437,455	58
Total	1,596,704		1,170,998		10,146,893		9,024,264	
From Connections								
Bituminous	47,448		92,894		671,724		334,56	
Anthracite	1,645,195		1,264,270		10,828,030		9,366,178	
Coke	34,256		30,764		215,253		165,700	

NORFOLK & WESTERN

The following is a statement of the tonnage shipped over this road during February and the first two months of this year, as compared with corresponding periods of 1913, in short tons:

	February		Two Months	
Coal	1913	1914	1913	1914
Tidewater, foreign	122,944	119,110	267,006	270,425
Tidewater, coastwise	337,202	311,679	646,120	649,333

DIVIDENDS

Central Railroad of New Jersey—Regular quarterly dividend of 2% payable May 1 to holders of record Apr. 17.

Lehigh Valley—Regular dividend on both the common and prefered of $1.25 payable Apr. 11 to holders of record Mar. 28.

The Reading Co.—Regular quarterly dividend on the common of 2% payable May 14 to holders of record Apr. 27.

St. Louis, Rocky Mountain & Pacific Co.—Regular quarterly No. 7 on the preferred of 1¼% payable Mar. 31 to holders of record Mar. 22 to Mar. 30.

Central Coal & Coke Co.—Regular quarterly dividend on the common of 1½% and 1¼% on the preferred both payable Apr. 15 to holders of record Apr. 1 to Apr. 15.

Island Creek Coal—Regular quarterly dividend on the common stock of 50c. payable May 1 to holders of record Apr. 23 and $1.50 on the preferred payable Apr. 1 to holders of record Mar. 23.

Westmoreland Coal—Dividend of 3½% payable Apr. 1 to holders of record Mar. 18 to Apr. 1.

American Coal Products Co.—Regular quarterly dividends of 1¾% on both the common and preferred, the former payable Apr. 1 to holders of record Mar. 25, and the preferred payable Apr. 15 to holders of record Apr. 10.

Financial Department

Colorado Fuel & Iron Co.

President J. F. Welbom, in the 21st annual report for the fiscal year ended June 30, 1913, says in part as follows:

Results—Gross earnings were $24,315,888, an increase of $47,435, and operating expenses amounted to $20,695,621, an increase of $199,451. Income from other sources increased $78,936, making the net income, before deducting charges, $4,375,895, a decrease of $73,079. After providing for all fixed charges, including sinking funds, etc., there remained a surplus of $1,727,192. A preferred dividend of 4%, or $80,000, was paid July 1, leaving a balance of $1,647,192 to be carried to profit and loss.

A dividende of 35% on the preferred stock, amounting to $700,000, was paid out of profit and loss Mar. 20, 1913.

Bonds, Merger—In accordance with the action of the shareholders, taken on June 17, our $14,067,000 debenture bonds then held by the trustee under the Colorado Industrial mortgage, have been cremated and the properties of the Colorado Industrial Co. were transferred to the Colorado Fuel & Iron Co., thereby reassembling the properties under one head. The balance sheet in this report, therefore, includes all of the properties heretofore standing in the name of both companies, and shows their total outstanding bonded debt.

STATEMENT OF PRODUCTION FOR YEARS ENDING JUNE 30

Tons, 2000 lb.—	1912-13	1911-12	1910-11	1909-10

Royalties in adv	48,015	41,570			
Total	103,210,915	102,630,941			

Additions—To meet the increased demand for openhearth steel, the executive committees on Apr. 21, 1913, authorized the construction of three openhearth furnaces (at a cost of about $500,000), as an addition to the plant of 12 openhearth furnaces now in operation.

Wages—On Apr. 1, 1912, an increase was made in the wages of coal-mine and coke-oven operatives, which added approximately $25,000 per month to the payroll, and on Mar. 1, 1913, steel-works employees were advanced an amount which represented an increase of approximately $20,000 per month in that payroll; the total of these two advances equaling at least $500,000 per annum. These increases represented a charge to the fiscal year under review of approximately $300,000 more than was borne by 1911-12.

Note—For the previous annual report of this company, see Coal Age, Vol. 3 p. 358.

Pennsylvania R.R. Coal Properties

The annual report of the P. R.R. for the year ended Dec. 31, 1913, has the following regarding its coal holdings:

In accordance with the policy heretofore announced as to the proposed sale of this company's security holdings in the anthracite coal companies owning properties served by its system, namely, the Susquehanna Coal Co., Mineral Railroad & Mining Co., and the Summit Branch Mining Co., your board deemed it desirable to first compact the ownership of the securities and properties of these coal companies into the Susquehanna Coal Co. Therefore, there has been sold to the Susquehanna Coal Co. the capital stock and debt of the Summit Branch Mining Co., held by your company, and upon the transfer of its property and rights to that coal company the Summit Branch Mining Co. will be dissolved. Your company is also the owner of one-third of the capital stock of the Mineral Railroad & Mining Co., the balance being owned by the Northern Central Railway Co. That company operated lands leased from the Northern Central Railway Co. and from the Manor Real Estate & Trust Co., but being unable for many years to pay the prescribed royalties, it transferred its 999-year leases to the Suspuehanna Coal Co., effective Jan. 1, 1914, and steps have been taken looking to the dissolution of the Mineral Railroad & Mining Co. The lands of the Manor Real Estate & Trust Co., operated by the Mineral Railroad & Mining Co., have been sold to the Susquehanna Coal Co., and negotiations concluded for the sale to it of the other lands operated by the Mineral Railroad & Mining Co. for the Northern Central Railway Co. subject to fixing the final price. Under the foregoing arrangement payment for said lands will be made by the Susquehanna Coal Co. in its 5% -5-year gold bonds, which are exchangeable for its first mortgage bonds if and when the same are issued by that company.

The purpose of vesting the ownership of these properties in the Susquehanna Coal Co. is to insure the continued operation of the unprofitable as well as the profitable mines, and thereby conserve the coal supply, and so that should a purchaser be found for the securities of the Susquehanna Coal Co., held by your company and the Northern Central Railway Co., the new owners will obtain possession of the properties subject to these mining obligations.

They describe the very latest

CENTRIFUGAL PUMPS

CAMERON

The Cameron Double Suction Volute Centrifugal Pump is adapted for medium head service.

Its design is the simplest. The casing is horizontally split, allowing quick, easy access to all working parts. The impeller is enclosed and perfectly balanced.

In mine service requiring capacities from 50 to 7500 gallons a minute, this pump has proved to be very economical. Its efficiencies are high, and the upkeep low. It may be direct connected to electric motor, or other forms of power drive.

The Cameron Multi-stage Turbine Pump is strong, sturdy and serviceable.

For high head service it meets the demand not only for a dependable but also an economical pump.

Its efficiencies are high, and continue over long periods of service. This advantage is fully realized where you have long, steady pulls of pumping, as in mine work.

It is a very compact pump. All parts accessible by means of the horizontally split casing. **Built in two, three and four stages, for a wide variation of speed and capacity, and any motive power.**

The Cameron Single Suction Volute Pump is the pump for low head service.

It has the fewest number of parts. The impeller is of the open type, made of hard cast iron, carefully ground to fit the casing closely and insure perfect balance.

All the way through this pump is simple, strong and rugged. It is unusually efficient in handling mine water containing grit and small solids. It may be driven by electric motor, or other forms of power apparatus.

Standard sizes up to 12 inches are kept in stock for immediate delivery.

You know the reputation of the Cameron Pump. The training and experience gained during half a century in building pumps insures in these new types the very best design, materials, workmanship and performance. ¶ These CAMERON CENTRIFUGALS will give you splendid service. Investigate their merits. See page 35 for advertisement on Cameron Steam Pumps.

Barsteel Heavy Haulage Locomotive

4 Features of Baldwin-Westinghouse Barsteel Electric Mine Locomotives That Assure Maximum Tonnage with Least Expense

The Cast Steel Bar Frame which gives great strength with least weight; permits easy access to, and excellent ventilation for the motors.

The Vauclain Removable Gib which greatly facilitates the removal of journal boxes and permits inspection or replacement of all wearing parts with a small cost of time and labor.

The Oil and Waste Lubricating System for the motors, with specially designed bearings for long life in service, which has been adopted as a standard after years of investigation.

The Commutating-Pole Motors which insure sparkless commutation at all loads. As a result, the commutator and brushes are long lived and require little attention, brush renewals are seldom required, and carbon and copper dust inside the motor is practically eliminated.

These features are but few of many which have been incorporated in Baldwin-Westinghouse **Barsteel** mine locomotives in order to give the user the greatest possible service. You can obtain them only when you specify Baldwin-Westinghouse.

Address either company for full information.

Putting It Down In Black And White

The Weekly Ad-Talk Page

¶ "That is a thing I can *say* to a man but I can't put it down in black and white." ¶ This is a very frequent attitude with the non-advertiser—he is actually *afraid* to back his goods in plain, cold print from which no man can get away. ¶ There are of course, some facts in every business, which it is not well to spread broadcast. ¶ But generally beware the man who will *say* what he wouldn't put down in black and white. ¶ And, conversely, pin your faith to the manufacturer who makes it a practice to put his claims and promises down in cold type as a bond for his good faith. ¶ In short, buy advertised goods!

COAL AGE

Vol. 5 NEW YORK, APRIL 4, 1914 No. 14

There are plenty of people who really and truly believe that most coal-mine owners are hard-hearted, grasping individuals, who spend their time hatching schemes which will enable them to stifle legitimate competition, or tie down their employees, and a little inquiry among your friends and acquaintances will probably convince you that such opinions are held, not alone by the ignorant, but by many intelligent people who seem to be conscientious seekers after the truth.

Of course, when you ponder a moment and recall that the only interesting articles about the coal industry that appear in the daily papers have to do with explosions (generally attributed to carelessness and greed of the mine owner), strikes (the miners' officials always insist that all violence is incited by the thugs in the employ of the operators) and coal famine among the inhabitants of city tenements during blizzard weather (generally illustrated with cartoons), you will understand how these wrong impressions have been formed.

If you should tell all of your friends that the average profit on a ton of coal, f. o. b. railroal cars at the mine, is under 10c. per ton, most of them would think you crazy and the remainder would be so little impressed by the simple statement, that they would forget about it within the hour. You must make a startling statement of fact, if you desire to erase an impression created by careless and uninformed news correspondents.

To illustrate: In a certain large city, not so far from a coal district, domestic coal was being delivered at $4.50 per ton. This $4.50 was divided as follows:

Lump Coal f. o. b. cars at mine	$1.50
Freight	1.60
Hauling in town	.50
Retail dealer's commission	.90
(This had to absorb all bad debts, etc.)	
	$4.50

During a period of extreme cold weather, one of the dailies began to feature the usual articles about the robber coal barons. A certain coal baron, having no sense of humor(?), decided to let the newspapers in on the ground floor, and so, made an offer to the associated charities of the city, to donate to them, at the mine, as many tons of coal as the newspapers would agree to have handled by the railroads and then delivered to the needy.

This looked mighty good to everybody; but when the business managers of the newspapers got to figuring, they treated the editor who had stirred up the trouble, to some sure enough excitement, and no newspaper in that city has printed a cartoon, describing coal barons, since that memorable famine.

Ideas and Suggestions

Are the Services of Mine Officials Fully Appreciated?

SYNOPSIS—Many foremen and superintendents spend a lifetime in the service of some companies without proper and adequate remuneration. One sure way to repress loyalty is to cause men to believe they are working for wages alone.

What does the coal-mining business hold out to the average mine foreman and superintendent to stay in the game? We know of several concerns operating a number of mines who can point to men grown gray in ten, fifteen and twenty years' service as foremen or superintendents, while during the period of their service, several general managers and general superintendents imported from other districts have come and gone without achieving any striking or lasting results.

Some of these foremen—excellent fellows by the way—never attained a superintendency, and the best of the superintendents who, by reason of their intelligence and loyalty, achieved such sobriquets as "Old Reliable," "War Horse," etc., never advanced to the position of general superintendent for the company they served so long.

Does it not appear strange that such men continued to give faithful service to one new general manager after another? But the reason is plain. As a rule they stayed because they become fixed in habit and yet believed that perhaps some day the concern would get tired of changing practices, spending money, etc., as the result of importing new managers; and the hope was ever present that they themselves would find their opportunity to fill the coveted place.

After all it only takes two or three such disappointments to make a man realize that he is getting too old to change companies. The result is that many good executives are side-tracked, and knowing how hard it is to pull up and move, they stay and do their best. This is so essential a factor after all to the successful operation of mines, that the job they have is theirs for keeps, but nothing better.

A great deal is heard nowadays about "efficiency." The superintendent more than any other man is expected to get the results, "scientific management" and "efficiency" hope for. But what of the superintendent himself? Is anything in the way of reward held out for him in seeking the accomplishment of almost hopeless tasks? He is the man expected to deliver the goods. Is he sufficiently paid for it?

How many coal-mine superintendents can count *years* between salary advances? Logically and naturally a superintendent is paid what is properly termed an individual rate. He is paid for his worth in the position he holds. The fact that so many men go from one company to another is proof of this. But what of the great number who remain loyal to one concern? Does the management see that their faithfulness and value because of their experience, etc., are rewarded?

It may not read well in cold print, but there are many honest and efficient men, capable of filling positions as general superintendent and general manager, working today as foremen and superintendents for concerns who have imported from other districts men of far less knowledge of the mining game, and especially of local conditions, to lord it over these same men, because the newcomers bear the official cognomen of general superintendent or general manager. The old employees carry the load and in most cases deserve the credit for any success achieved by the imported "G. M." When the latter did not achieve success, were they let out with him? Certainly not. The company knew better.

It is generally admitted that the man who works just for his pay is not the best workman. However, some companies appear to treat some of their oldest and most loyal employees as if they were working for their wages alone. *They are not.* They are working for the *honor* of proving their faithfulness and loyalty. This is worth as much to some of them as their pay. But the recognition of this honor on the part of the company which should be given in annual salary increases, is in too many cases overlooked or withheld too long.

Loyalty is not going to become extinct. It is a tremendous influence in the adherence of men to one concern for the best years of their lives. When loyalty does become extinct and all men work for pay alone, it will be a sorry state of affairs.

The best way to repress loyalty is to withhold appreciation for it in the salary check. We heard of a man who held a responsible position with a big concern, but whose rate had not been changed for several years, who wrote his boss asking for a change in rate. He said: "Increase it or decrease it, just as you like—what I'm after is a change." It is not going to hurt a good mine foreman or superintendent to voluntarily raise his salary once a year. The man who can't stand it is the one you must locate sooner or later. From those who do stand it, an increasing quality of service will be obtained. Look over the list of your old employees. What you find in the way of salary recognition (or lack of it) may surprise you.

Pass It On

Look over the trade periodicals on your desk this morning; also step out in the back room where you keep your office supplies and take stock of the publications you have piled away for future reference. There must be quite a stack of them out there gathering dust and occupying much needed space. How many times have you gone into that supply room to run through the back numbers and dig out an article you recollect vaguely of having seen some time or other? Not very often; have you?

Again consider those magazines just laid on your desk among the morning's mail. Do you go through them carefully? The chances are that when you pick up one, you turn the pages quickly, noting only the illustrations, until you come to an article bearing on your own particular product. This you skim over hastily, or digest carefully, as the importance of your correspondence allows. Again you move along rapidly, stopping a moment to note market quotations, until finally you toss the magazine to the back of the desk, with the mental remark that you will look through it again when you have more time.

How many men in your organization, or under your orders, ever see that paper to which you can spare only a scant quarter of an hour? Many of those men are ambitious; some are real thinkers. They may need only the word picture of how other men are solving problems common to your business to start them to thinking about the unconquered difficulties right in your own plant.

More than one great manufacturing organization of the present day owes its success to the discovery of the simple truth that the more brains there are focused on certain problems, the better chance those problems have of being quickly and surely solved. Trade books and publications so disposed that they can be looked over and their articles of interest discussed during leisure moments, such as the noon hour, make one of the best ways of awakening interest in the work at hand.

Did you ever think of the tremendous amount of labor required to analyze the latest developments and ideas in a particular field; to investigate the newest apparatus and processes; in short to produce a useful readable business magazine? That periodical into which you look for a few moments contains the best thoughts of a score or more of men who are top-notchers in their lines.

Has your business got all the benefit possible out of that magazine which you will soon lay aside to continue the morning's dictation? Cannot some of those men, on whom you rely for the smooth and noiseless operation of the business machine, glean one more idea from its pages? Even one useful idea may mean thousands of dollars in plant economies or improved product.

Therefore; for the inspiration of your men and the advancement of your business; after you have read your trade paper, *pass it on.—Power.*

Interesting Ideas Developed at an Alabama Mine

The accompanying photograph illustrates several very interesting ideas that have been developed by W. J. Lovejoy, mine foreman at the Acmar slope of the Alabama Fuel & Iron Co., Acmar, Ala.

In the foreground is a stretcher which can be placed on top of a mine car or a lumber wagon and a patient transported on same will be quite as comfortable as if he were riding in an invalid's carriage.

VIEW AT ACMAR MINE OF ALABAMA FUEL AND IRON CO., IN ALABAMA

Just back of the stretcher, is the railed-manway entrance to the mine. Every man entering the mine first passes the fireboss' shack, where he is given instructions by the fireboss, if any instructions are to be given. He then passes through the turnstile, which is shown just under the circular disk fastened to the side of the fireboss' shanty. Around the circumference of this disk are notches which are numbered consecutively, and each time

a man passes through the turnstile, the disk is advanced one notch, thus registering automatically the number of men who have entered the mine.

Just beyond the turnstile are the checkboards; one for in and one for out. With this arrangement, a man cannot forget to see the fireboss before going to work, nor can he enter the mine without being accounted for, to the officials.

Acmar produced the largest tonnage of coal at any mine in Alabama, for the year 1913, namely 443,026 tons. This is a rather remarkable record, considering that the mine was opened in October, 1911, and only ran 275 days during 1913. The coal seam is pitching and all coal is hauled to the surface up a single-track slope.

Pumping in Coal Mining

The question of pumping, in the operation of a coal mine, is a very important and often expensive one. Some of the problems that arise are difficult ones to solve. Especially is this true in mines under shallow cover and in the working of seams that outcrop on the hillside and dip into the hill.

It often happens that the desire to get quick returns has resulted in the coal being worked out close to the crop. On going into mines of this class, it is common to find water coming in from all sides, often in small streams. As long as the flow of water is regular, it is possible, by a proper system of ditching and the use of siphons to conduct the water to sumps located in the mine at convenient points, to control the water and keep the mine in working condition.

It is, however, in the class of mines to which I have referred where the coal along the outcrop has been worked out and surface drainage enters the mine, that the greatest trouble is experienced in reference to keeping the mine in working condition, at certain seasons of the year. During heavy rains and spring freshets, so much water enters the mine through the outcrop, that it is, in many cases, practically impossible to prevent the drowning out of the working places. This condition may continue for several days.

To install a sufficient pumping capacity to handle the water at such times would mean that many pumps would stand idle the greater part of the year. Such inrushes of water cause the operator much uneasiness. The extra pumping equipment may be necessary to insure the safety of his mine, to say nothing of keeping the mine in working condition. A considerable investment is thus often tied up in equipment that is useless a large portion of the time.

It is with the hope of saying something of benefit that will enable some engineer or operator to overcome these difficulties, that I offer this short article. COAL AGE, as a mining paper, has no equal in the way that it gives the reader a wide and practical insight into all kinds of mining questions.

Referring to the conditions I have mentioned, I would advise the building of dams to hold back, temporarily, such an inrush of water as I have described and would suggest that, in the development of almost every mine, there are some vacant or abandoned "flats" or "levels" that have been developed and are being held for the finishing of the dip workings. My suggestion is that, in many instances, such places could be sealed off by a substantial dam, so as to form a storage reservoir, capable of receiving and holding the quantity of water that is in excess of the regular pumping capacity during any inrush of water into the mine. In adopting such a plan, arrangements should be made by which the water flowing into the mine could be diverted and drained into this reservoir.

By this means, it would only be necessary to maintain a pumping plant of sufficient capacity to handle the average daily amount of water made in the mine. During wet seasons, the water in excess of this daily average amount could be stored in the reservoir thus provided; and, in the drier seasons, the pumps could be made to drain this area.

Wherever such a plan can be adopted, it would save a large and useless equipment and would avoid the additional expense that would be required to provide extra men and fuel for the operation of the pumps, at certain seasons of the year.

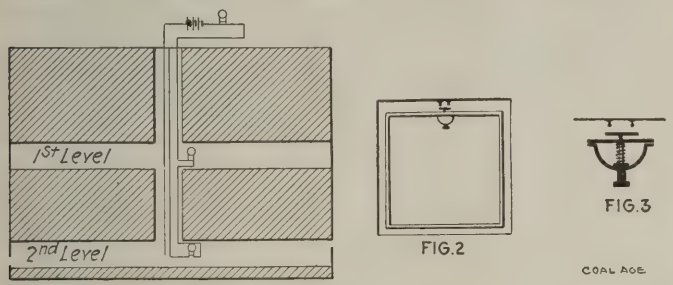
Anthracite Dust Not Explosive

HARD-COAL OPERATORS DELIGHTED—PREVIOUS JUDGMENT CONFIRMED

A series of important tests have been conducted during the last two weeks at the Bureau of Mines' station at Pittsburgh, and the experimental mine, near Bruceton, Penn., to determine whether Pennsylvania anthracite dust is explosive when firedamp is present. The culminating experiments were carried on Mar. 24, at the Pittsburgh station in the presence of Messrs. James E. Roderick, chief of the Pennsylvania Department of Mines, Harrisburg; M. J. Brennan, inspector, Pottsville; A. B. Lamb, inspector, Shenandoah; S. J. Jennings, inspector, Pittston; D. T. Davis, inspector, Wilkes-Barre; G. B. Hadesty, division superintendent; Mr. Garner and Mr. Price, representing the Philadelphia and Reading Coal & Iron Co.; W. G. Whildin, general superintendent of the Lehigh Coal & Navigation Co.; W. S. Norton, chief engineer of the Alden Coal Co.; H. R. Owens, of the Lehigh Valley Coal Co.; W. Gordon Thomas, of the Lehigh & Wilkes-Barre Coal Co.; Charles Enzian, the representative of the Bureau of Mines, Wilkes-Barre; George S. Rice, chief mining engineer, and Spencer P. Howell, explosive engineer of the Bureau, both of Pittsburgh.

The tests have been of tremendous interest to all those concerned in mining anthracite, since there are large amounts of anthracite dust unavoidably made in mining, and if the dusts were inflammable it would be a very serious problem, almost impossible to overcome.

The British experiments in their experimental gallery have indicated that the Welsh anthracite is inflammable, and this awakened some doubt whether the Pennsylvania anthracite dust might be inflammable. To the great delight of all who witnessed the tests, not only did the anthracite dust not prove explosive without firedamp being present, but even in an explosive mixture it did not prove inflammable, and also tended to lessen the length of flame of an explosive firedamp mixture.



Chief Roderick believed that the matter was of such great importance to the anthracite industry that he brought four of his inspectors from Luzerne and Schuylkill counties, which contain perhaps the most gaseous mines in the world. He expressed himself as being greatly

pleased with the conclusive demonstrations. While he and other inspectors and operators of the anthracite district have been very positive from results of many years' experience that the anthracite dust was not inflammable when firedamp was not present, they hitherto could not assert that it might not extend the flame of the firedamp explosion. Now they think that it has been shown beyond question that its presence tends to limit rather than extend the flame.

A Safety Caging Device

Last June a patent was granted on a safety device for a shaft cage, which promises to help the "Safety-First" movement. By the use of this invention, the danger of riding a shaft cage is reduced to a minimum. Should anything happen while the cage is in motion, the pressure of a button signals the engineer to stop; likewise signals may be given to raise the cage or lower it as may be desired.

The invention is nothing more than the application of the principle of the electric bell. Fig. 1 shows a vertical section of a shaft, illustrating the method of wiring. Two

General and Detail Sketch of Apparatus

lines of No. 6 copper wire, parallel to each other and about 4 in. apart, are run from the top to the bottom in both compartments of the shaft. These wires are connected with storage batteries and electric bells, one of which is located in the engine room and the others on the different levels, or wherever desired. Fig. 2 shows a plan of a shaft and the relative position of the circuit-closing apparatus is shown in detail in Fig. 3.

The contact bar, which is of copper, is held in position by a coiled spring under tension. When the button is pressed the contact bar touches both shaft wires, thereby completing the circuit and ringing the bells. This is attached to the cage directly under the bonnet and in such a position as not to interfere with the caging of the car or the dumping of the coal.

The argument may be advanced that the device is unreliable in that the circuit may be closed either by the bonnet or other metallic parts of the cage. This can only happen by the offending parts being disarranged and is really an argument in favor of the device, for should such a thing happen, it would merely be a case of the cage reporting that it is in need of prompt attention or possibly immediate repairs.

The apparatus has the approval of government officials and has been installed at No. 15 mine of the O'Gara Coal Co., Carrier Mills, Ill., by Mr. Schellenger, the inventor, at which mine he is employed as hoisting engineer. Those who have tried the device say they have found it to be a complete success.

Mine Caving Prevented by Hydraulic Filling

Hydraulic filling of the abandoned mines in the anthracite region is the only solution of the mine-cave problem, in the opinion of Charles Enzian, local engineer for the anthracite district of the Federal Bureau of Mines, who has just submitted a report to the Federal Department of Labor, embodying recommendations as to what is best to be done.

Mr. Enzian states that hydraulic filling is practicable and profitable, and was devised for the double purpose of disposing of refuse and the reclaiming of pillars. He states that it is also bringing about the elimination of the unsightly spoil banks, and that this waste, caused by an exacting market, will soon be the exception rather than the rule.

He also maintains that it will eventually prevent the pollution of streams and injury of river flats, which are subject, after floods, to deposits of culm mixed with fine clay, loam and silt.

"State and local regulation," he continued, "were directed against such conditions and a number of civil and criminal suits at law hastened the installation of the filling systems, the operations of which produced, and will continue to produce, valuable results.

"The extent of stream pollution and of land damage as a result of dumping mine refuse along water-courses is often under-estimated, but may be realized by a casual survey along rivers with tributaries among the coal fields. Almost every spring the tributaries overflow their banks and enormous quantities of culm and silt are washed into the rivers, which deposit the mixtures on the lowlands and in the channels of the rivers.

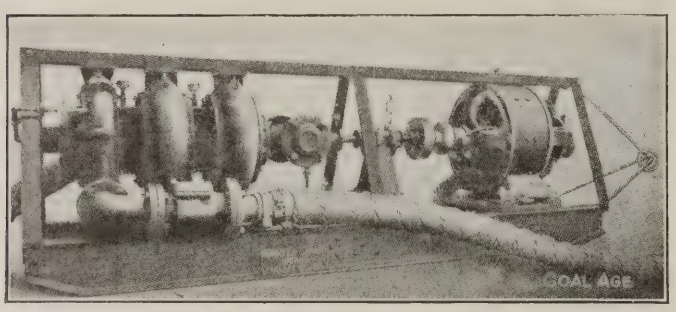
"Not only is the transported material a source of destruction to vegetation along the bottom lands, but the action of the streams involves a great waste of natural resources, as proven by the fact that during the years of 1910 and 1911, over 90,000 tons of coal were dredged from the North Branch of the Susquehanna River, several miles below Wilkes-Barre."

Mr. Enzian points out the fear entertained by property holders and contends that hydraulic filling should be utilized more extensively because it permits of higher extraction, will prevent cave-ins and will prove valuable in extinguishing mine fires and for arresting squeezes.

He points out the aid which can be given by cities, saying that ashes and garbage, by proper arrangements, could be dumped near hydraulic filling plants and by this means conveyed into the mines at predetermined points. Mr. Enzian also suggests that many industrial plants could use this very system to advantage. Railroad companies could, moreover, secure large quantities without much expense by conveying the ashes from the industrial centers in the cars that are now taken back empty.

"The availability of sand, gravel, loam and river silt are now limited to the northern field," he continued, "but if the various glacial silt deposits in the Wyoming and Lackawanna Valleys can be made available the problem of procuring material for hydraulic mine filling can be considerably simplified."

He stated that several attempts had been made, but failed, and that he believed the failures due more to lack of persistent effort and to crude methods than to the engineering impossibility. He also pointed out that along the Lehigh Valley, as far east as Bethlehem, and in the iron- and zinc-ore belts of New Jersey, large quantities of zinc slag could be obtained. Mr. Enzian contended that crushed stone might also be used, though its practicability has not yet been determined. He inferred, however, that the cost would not be so great as imagined.



Self-Starting Motors for Mine Pumps

By W. H. Easton*

SYNOPSIS—Some notes and comments on the advantages of self-starting electrical apparatus, as applied to coal mining. Remote control is one factor that may often be used to advantage.

The self-starting, direct-current electric motor for mine service is a comparatively recent innovation, but it has proved highly successful in operation and has become popular among operators who have used it. Mechanically, the self-starting motor is similar in every respect to the ordinary direct-current motor and most of the electrical features are the same, the only difference being in the fields. In the ordinary motor the fields are usually "lightly compounded"; that is, there is a shunt-field winding and a light-series winding. In the self-starting motor a heavy-series winding takes the place of the light one.

The difference from an operating standpoint is that the ordinary direct-current motor must be started by

Typical Application of Direct-Current Self-Starting Motor. Pump Is Mounted on a Skid to Be Lowered Down an Incline

means of a starting box, in which there are several steps of resistance that must be cut out gradually as the motor speeds up; if the motor, while at rest, were subjected to the full strength of the current, it would simply burn up. The self-starting motor, however, by virtue of its heavy series field, can be connected directly to the line and will start gradually and without injury.

Advantages of the Self-Starting Motor

This motor has three distinct advantages, as follows:

1. Possibility of Remote Control—The ordinary motor must in general be started by visiting the motor and turning the lever of the starting box by hand. The self-starting motor needs no such attention. All that is necessary is to close the circuit-breaker of the motor circuit in the power house and the motors start up automatically.

Furthermore, when the power fails temporarily for any reason, the motors, of course, stop, but when the power returns the self-starting motors start up at the same time. Ordinary direct-current motors will not do this, as the starting box is so arranged that it is automatically thrown to the off position when the power fails and so each must be visited in turn. Where there are many widely scattered motors, considerable time is necessary to start them, a loss entirely eliminated by the self-starting motor.

2. Elimination of the Starting Box—Since the starting box is eliminated, it follows that the motor connections are of the simplest possible character with no contacts, resistance, and complicated wiring to cause trouble as a result of dampness and corrosion. While starting boxes can be obtained that are proof against corrosion, it is obviously advantageous to do away with them.

3. Compactness of the Equipment—The unit formed by the pump and motor is entirely self-contained except for a simple knife switch. It is, therefore, more easily installed and moved than the ordinary type with its starting box and wiring.

Direct-current, self-starting motors can be furnished in sizes up to 20 hp. for 220- and 500-volt circuits. The maximum full-load speed is 1100 r.p.m., as this type of construction is not practicable with motors of higher speeds. Squirrel-cage alternating-current motors of the same ratings can also be thrown directly on the line, but no special changes in construction are required for this type of motor.

Starting Current—One fact that must be borne in mind with these motors is that on starting they draw several times full-load current from the line. This is ordinarily of no importance since the time during which this heavy current is required is short and the starts are few. Under some circumstances, however, the heavy load proves objectionable. By dividing up the motors into several groups so that only a few are started at once, the total instantaneous rush of current may be reduced.

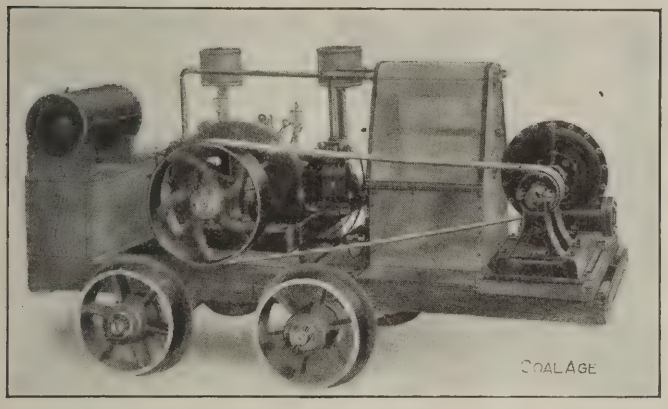
Speed Regulation—Another factor of importance is that the no-load speed of these motors is greater (sometimes as much as 50 per cent.) than the full-load speed. Where the motor is directly connected to the load this is of no importance, but they are not well adapted to driving machines that may be lightly loaded or to connection by means of belts since the belts may break.

Applications

The self-starting motor finds its ideal application to the centrifugal pump and mine fan or blower. It has demonstrated its usefulness in this field and a large number have been in successful service for several years.

It has also been used extensively for driving triplex plunger pumps, although the motor manufacturer has been loath to recommend it for this service. It has, however, made good for this purpose, and if the motor manufacturer is fully informed of the intended application, he can, in most cases, supply a satisfactory drive. Crushers, coal conveyors and other machines have also been successfully driven by these motors, but the same caution applies to these uses. For damp locations, the coils should be impregnated so as to render them moisture-proof. This process greatly adds to the reliability of the motor under the severe conditions of mine service.

The price, it may be said, is but little higher than that of the ordinary compound-wound motor of corresponding size and speed. Vertical, inclosed, back-geared and other modified types, as well as the standard horizontal open type, can be obtained.



*Westinghouse Co., East Pittsburgh, Penn.

A Portable Self-Contained Mine Pump

By A. W. Dickinson*

In many mining districts, where the deposits sought have only a shallow cover, the ingenuity of the operator is frequently taxed to devise a means of ridding the workings of surface water. Where the area of the mine is small, and the water can be easily drained to a central point, it is a simple matter, but where the mine covers a considerable area and electric power is not available scattered bodies of water may become troublesome.

In the Bevier coal field in Macon Co., Missouri, the Central Coal & Coke Co., of Kansas City, operates a slope opening known as Mine No. 25. The coal bed is

A Unique Style of Portable Mine Pump Designed for Special Service

flat and the face is nearly a mile from the slope collar. As the cover is thin (in many places not exceeding 30 ft.), there are numerous fissures or cave-holes which allow water to enter. Where the influx from such sources cannot be ditched to a sump, it is necessary to employ water-boxes.

The water-box may be efficient for small quantities of water on a haul not exceeding 600 ft. in length, but if it is necessary to move the liquid further, other means should be used, as the water-box is not only costly for long hauls, but interferes with gathering.

The writer conceived the idea of placing a number of pump stations near the working face, where the water was giving trouble, and utilizing a portable gasoline-engine-driven pump. Five stations were accordingly located with a pump at each. Two holes were drilled from the surface at each station, one to take a 1½-in. pipe and the other a 2-in. pipe. A gasoline engine of 8 hp., and a centrifugal pump with 2-in. suction and 1½-in. discharge were arranged on a mine car bed and the unit started on its rounds. The exhaust from the engine was led up the 2-in. pipe to the surface, while the discharge of the pump passed up the 1½-in. pipe.

This pumping outfit in charge of one man was in continuous operation for 8 months, being a success and, to a large extent, solving the water problem. At the end of this time, the Hayton Pump Co., of Quincy, Ill., following my suggestions, furnished another similar portable unit shown in illustration.

Four pumps of this type are at the present time in use, the metal of each having successfully withstood the action of the acid water and the grit from the sump.

*Superintendent, Central Coal & Coke Co., Kansas City, Mo.

A New Horizontal Mine Pump

An interesting type of horizontal mine pump is that which recently has been placed on the market by the Deming Co., of Salem, Ohio.

The air chamber is built very low and broad, so that the pump can be taken into shallow entries. Access to the discharge valve is obtained by removing the air-chamber, which is held in place by six bolts. The water end is unusually heavy, being constructed of cast iron to resist mine water. The valves are of rubber and are mounted on bronze grid seats screwed into the deck. The piston rod is of bronze and works through a deep

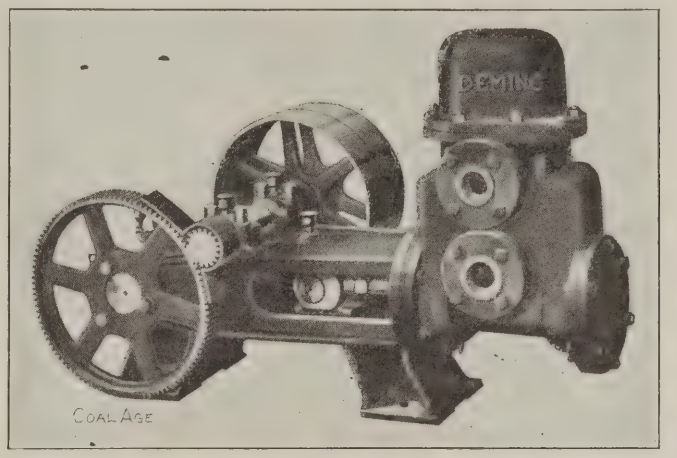


Fig. 1. A 6x6-In. Pump Having Capacity of 55 Gal. per Min.

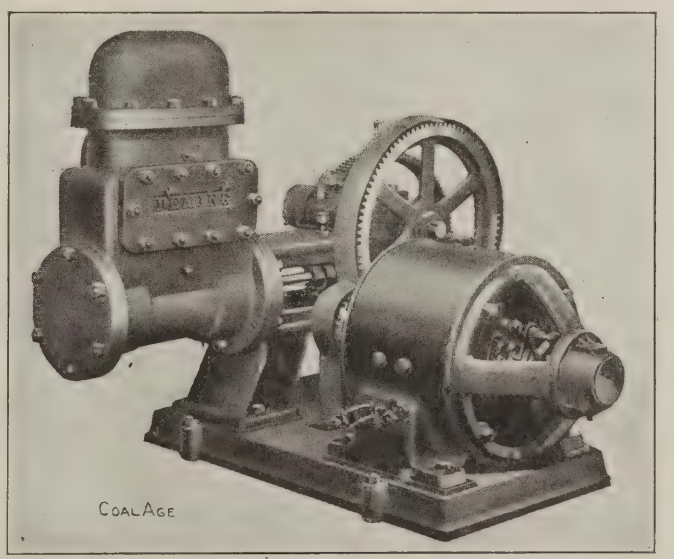

Fig. 2. Same Pump Fitted with Sub-Base and Gearing Connection for Motor

stuffing-box with bolted gland. The cylinder is fitted with a heavy bronze liner.

The illustrations show the 6x6-in. pump, which has a capacity of 55 gal. per min., when running at 55 revolutions. These 6x6-in. pumps are fitted with 3-in. suction and 2½-in. discharge pipes.

The standard construction includes tight and loose pulleys, with grease cups and wrenches, as shown in Fig. 1. The pump can also be fitted with a sub-base, and with gearing connection for the motor, as shown in Fig. 2. These pumps are intended for a 75-lb. pressure.

The Proper Choice and Care of Mine Pumps

By C. W. Crawford*

SYNOPSIS—The writer gives a few practical pointers showing what conditions should be considered in erecting a mine pump and what precautions should be taken to secure to it the best results and longest life.

The discharging of water and the choice and care of pumps are prime sources of worry in mining operations. No operator can go home at night with assurance that his mine will be running in the morning; the superintendent is liable to call at any hour, and the mine even may be laid out for days at a time. Pumps are chosen for their local popularity, or for their cheapness; and, more often than otherwise, too small a pump is installed, with the result that it must be pushed beyond its endurance. Fifty strokes a minute is fast enough for the majority of pumps, but the pump makers recommend one hundred, hence the user is encouraged to thrash his pump to death before he realizes it.

Pumps are erected usually by the pump man, who uses whatever material he can get; the superintendent ordering whatever equipment he has in stock, if any, which is usually one or two sizes too small—never too large. Short elbows are used almost universally and air chambers frequently are ignored. No thought is given to the velocity of the water in the pipes; a pump being considered a good one when it discharges, horizontally, a full pipe at the surface, regardless of power and obstructions.

The water is compelled to travel at six or seven times the velocity of the piston, instead of three or four, with the result that half the power is absorbed in friction and in butting against short elbows. Usually, the air chamber is water-lagged, and the column of water has to be started at each stroke from a dead rest. Frequently, the air is let out of the air chamber by a cock at the top, or half way up. No provision is ever made to supply the air chamber with air, unless by an unintentional leaky suction pipe. Packing of the piston is neglected as long as water appears at the top, and the sloshing backward and forward on the piston head of the loose packing and the follower often cause broken pump rods. Bad or cheap packing is sufficient cause for scoring cylinders and pump rods.

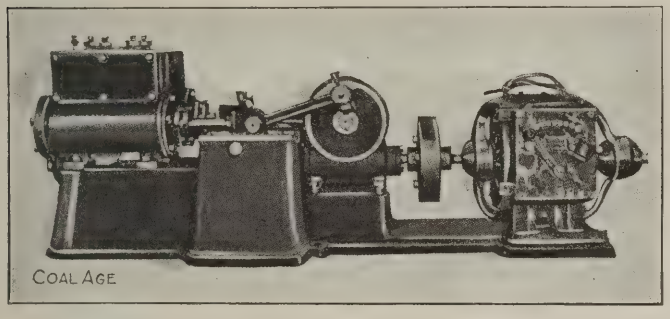
These are some of the abuses mine pumps are subjected to, but many of them can be, and ought to be, corrected. Acid mine water can neither be ignored nor combatted with impunity or any hope of permanent elimination. Pumps are made comparatively acid-proof, but it requires the utmost effort of the pump maker and the pump user to accomplish even moderate success, and they do not always work together. "Where there's a will, there's a way," and confident coöperation of pump maker and pump user could be made to alleviate somewhat the ills both parties have to contend with.

Pumps generally are ordered too small to meet the increased flow that is sure to come, forgetting that slower speed and fewer hours per day mean ultimate saving. The wear of a pump is in proportion to the distance traveled by the piston, regardless of the quantity of water discharged. The power expended is equal to the horsepower of the load plus the friction of water in the pipes, plus the obstruction of elbows, through this latter can be reduced by using long elbows. In the absence of long elbows, two 45-deg. elbows with a nipple between are a good substitute. Pipes larger than are prescribed by the pump maker ought to be used—the larger the better. Suction pipes should be fitted air-tight, and should have an air cock to admit a small quantity of air to replenish that carried out of the air chamber by the water. It is not known generally that water under pressure in contact with air absorbs the air, thereby reducing the hydrostatic pressure of the column and exhausting the air chamber, with the result that a constant supply of air is required to keep the air chamber filled. The folly of the pump engineer letting this air escape by a cock is too preposterous for common belief, nevertheless it frequently is done.

Pump pistons, or plungers, ought to be packed with soft packing—the softer the better—but braided, and filled with tallow and graphite. The packing should be screwed up solid and kept so by frequent examination. Also, the packing should be renewed frequently by repacking with the same material refilled with tallow and graphite. If this were done, cylinders of genuine babbitt metal could be used in all acid mine waters, as well as pump rods covered with genuine babbitt. This bit of information may be rated as superfluous by pump men, but it already is being used with success and general satisfaction.

Pump cylinders generally are made of a composition called bronze, or phosphor-bronze, containing zinc. The zinc is used to obviate the air bubbles that are inevitable in casting copper and tin-phosphorus, being a scavenger, to clean the metal; the zinc fills up the chinks, as it were, and makes the metal solid. It is doubtful if the zinc fully combines chemically with the copper and tin. Anyway, the acid water dissolves the zinc and leaves the face of the cylinder as rough as a sheet of sandpaper. Pure phosphor-bronze, without zinc, wears smooth, but is a very rare composition, owing to the difficulty of eliminating air bubbles, and few shops use it.

Lead-lined pumps have met with unqualified success, being invulnerable against the corrosive action of mine water. In some localities pumps could not be used at all—the water being hoisted in tanks under the cage—until the introduction of the lead-lined pump. Ordinarily, pumps lasted six months, and solid bronze pumps one year, in extremely acid mine water, whereas the lead-lined variety are good indefinitely.



Electric motors have the perversity of running at their own power and speed, and hence the pump must have a resistance equal to the power of the motor. If its load is greater, it becomes overloaded, and the gearing and frame, therefore, must be inordinately strong, and apparently out of proportion with steam-driven pumps.

*President, Crawford & McCrimmon Co., Brazil, Ind.

Geared motor pumps are noisy and subject to breakage of gear; therefore, the general practice now is to drive with belts. Belts for this purpose in mines must be waterproof, and pumps equipped in this manner should be driven only at moderate speed.

A New Mine Pump

The J. C. Stine Co., Tyrone, Penn., have recently put on the market a new, direct-connected, electric, mine pump especially designed for hard service. A number of these pumps have now been in service in the mines of some of the largest coal companies for several months past and have given good satisfaction in every case. Some of these in use are operating under severe conditions; one in particular is reported as having been in operation 24 hr. a day during the past three months. Comparing the

THE J. C. STINE ELECTRICAL MINE PUMP

work performed by this pump with that of two other pumps manufactured by two of the largest pump builders in this country, one mine superintendent pronounces it as, beyond question, the best pump in operation in his mines. This superintendent has 15 electrically driven pumps working in the mines in his charge.

The J. C. Stine duplex pump is fully described in a circular just off the press and which enumerates its several special features, among which are the following:

The duplex cylinders are double acting and cast in a single piece. The power and water ends of the pump together with the intermediate connections are mounted on one solid casting, with all faces properly machined to permit any part to be taken off for examination or repair or to be replaced, without disturbing the other parts.

A balance-wheel coupling on the motor shaft absorbs all shocks or pulsations incidental to high-speed machinery and gives a constant torque. The speed-reducing device is said to be absolutely noiseless and simple, consisting of a bronze worm gear, meshing into a polished worm of high-carbon steel previously hardened. These worms are cut at such an angle as to give the highest possible efficiency, which careful tests have shown to yield 97 per cent. of power transmitted. The worms run in a bath of oil, being inclosed in a cast-iron gear case absolutely tight. The bearings are bushed with bronze, the bushings being renewable at slight cost; but this is not often required, owing to their being immersed in oil. Ball-thrust bearings at the ends of the worm shafts greatly reduce and practically eliminate friction.

Careful attention has been given to the anti-corrosive qualities of this pump. The cylinder castings are of dense cast iron, the cylinders being bushed with anti-acid metal. Where the mine water is very corrosive, the entire cylinder is cast in anti-acid metal, at a slightly extra cost. There are eight valve seats of large area, to permit the ready flow of water with slight frictional loss. They are made of anti-acid metal, accurately fitted and interchangeable. The valves likewise are of anti-acid metal filled with vulcanized india rubber, the metal casing resisting the pressure and protecting the rubber valves, which may be reversed, giving twice the wear.

The side plates, one on each cylinder, furnish ready access to the valves, which is an important feature in the design of mine pumps. All important parts exposed to corrosive action or wear are made of anti-acid metal or special Tobin bronze. The crossheads are fitted with large babbitted-bearing surfaces and have large, removable crosshead pins. The connecting-rods are of steel, both ends being bushed with renewable bronze bushings. The cranks are set at right angles on the crankshaft.

The Alberger Pumps of the Pennsylvania Coal Co.

About two years ago the Alberger Pump & Condenser Co. built for the Pennsylvania Coal Co. two turbo-centrifugal motor-driven sinking pumps. These units are being used for unwatering service in a mine which has been flooded for some time and is now being reclaimed. Each unit consists of a two-stage vertical-shaft centrifugal pump, with a circular cast-iron cradle-piece mounted on the pump body, on which the driving motor is supported. Each unit is 4 ft. 4 in. in diameter by 10 ft. 9 in. high, so that it is small enough to be lowered through practically any mine or water shaft. In this installation each unit is mounted in a steel float of sufficient depth and buoyancy to carry the load imposed by the equipment, and designed to lower in a shaft approximately 6x10 ft. between guides. Rods and bails are also provided for raising or lowering the unit as required.

Each pump has a capacity of 2000 gal. per min. against a total dynamic head of 350 ft., when operating at the full-load speed of an 1800-r.p.m., 60-cycle induction motor. The head of 350 ft. is the maximum which will be encountered in this case, but at the beginning of the operation when the water was high in the shaft, the head was about 100 ft. By correct impeller design the increase of load under heads lower than normal, which is characteristic of centrifugal pumps, is so limited that a 300-hp. motor is not overloaded under any condition of capacity or head. This is a desirable and valuable condition as it permits of handling all of the water which the pump will pass at the lower heads with a wide-open valve, and without increasing the load imposed on the motor to any considerable extent. Therefore, the gain in gallons per minute pumped is considerable, with a corresponding reduction in the time required for the whole operation.

In case the unit is required to operate in future in some location where the shaft is smaller, the pumps and motors can be removed from the floats, and as each unit is self-contained, it can be supported by a frame or bails and lowered by a hoist.

Inaccessibility in the working location was one of the principal difficulties encountered, but was successfully overcome, and the installation today represents a marked advance in the method of dealing with unwatering problems in the anthracite field, and one for which the engineers of the Pennsylvania Coal Co. deserve great credit.

Combined Air Lift and Pumping System

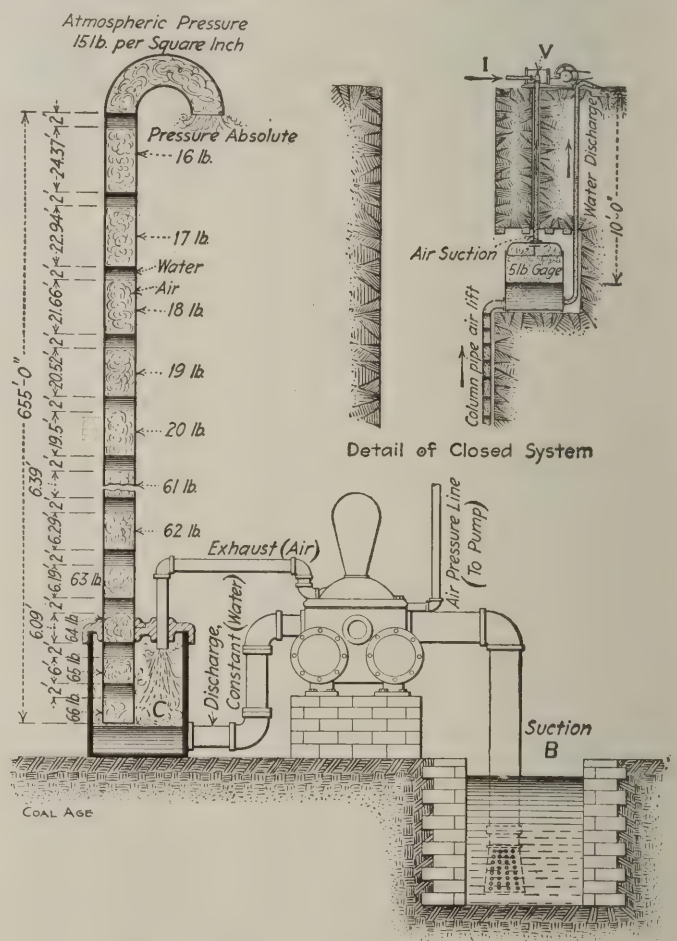
By Lewis Jones*

SYNOPSIS—General requirements of the Pohle air-lift compared with the systems in common use of pumping with steam or compressed air. Advantages of the Jones' combined air-lift and pumping system.

The Pohle air lift used in pumping water from a depth below the surface, is too well known to require a special description. As early as 1885, Doctor Pohle experimented with air introduced into the water column, which was thereby overbalanced by the greater weight of a shorter water column and, as a result, the water was lifted to the surface without pumping. It can be readily understood, however, that this system would require at least a 50 per cent. submergence of the column pipe, in order that the system may work with reasonable efficiency; and this was found not to exceed 65 per cent. at the best. For that reason, the application of the system, in practice, has been limited.

In his application for letters patent, Doctor Pohle showed the adaptation of his pumping system to mines, by sinking a well hole below the level of the sump in the mine and allowing the mine water to flow into this well. In the development of the system, it was further suggested that the air lift could be divided into stages.

For example, a submergence of the first water column to a depth of 50 ft. below the level of the sump in the mine, would suffice to raise the water to a height of 50 ft. above that level, by means of the air lift. At this point, the water was discharged into a standpipe, the lower end of which was at the level of the sump in the mine. this standpipe gave a submergence of another 50 ft. for the second-stage column pipe; and by its means the water was raised to a height of 100 ft. above the sump level.



As the efficiency of each stage would range downward from 65 per cent., the final efficiency of a multi-stage air lift is necessarily very small. It is these features of low efficiency and necessary submergence that makes the genral application of the air-lift system prohibitive in most cases of mining. Its legitimate field of operation is confined to the pumping of deep wells in which the water rises to a height sufficient to give the necessary submergence of the column pipe.

The most common system of pumping used in mining employs the direct-acting piston or plunger pump, which is generally operated by steam; but, in many cases, owing to the large losses by radiation in conducting the steam from the power plant to the pump, air is being substituted to operate the pump. The efficiency of the average direct-acting steam pump rarely exceeds 50 per cent. of the indicated horsepower of the steam cylinder, and often ranges as low as 40 per cent.

In the use of air for the operation of the pump, there are other considerable losses, the chief of which, perhaps, arises from the necessity of carrying the full air pressure for practically the entire length of the stroke, thus preventing the utilization of the expansion of the air in the cylinder. This full air pressure is necessary in pumping, because of the constant load and the absence of the flywheel for storing up the power in the early part of the stroke, for utilization in the latter part, during expansion. As compared with a first-class steam engine, the direct-acting steam pump uses from six to ten times the amount of steam, because of the inability to utilize its expansive power in the cylinder. This is also true in the use of air for operating the pump.

The Combined Air Lift and Pumping System

With a full knowledge of these conditions and requirements, Lewis Jones has devised a combined pumping-and-air-lift system, known as the Jones System of Compressed-Air Pumping. The general arrangement of the system is shown in the accompanying illustration. The prime mover in the system is a direct double-acting piston or plunger pump operated by compressed air. To this extent, the arrangement is identical with that of an ordinary compressed-air pumping plant.

Combined Air Lift and Pumping System

The special feature by which the Jones system of pumping differs from the common system is the utilization of the exhaust air of the engine, which is conducted

*Brooklyn, N. Y.

directly into the air chamber *C*, into which the pump discharges the water drawn from the sump or basin *B*, shown on the right. At each stroke of the pump the water discharged into the chamber *C* rises to a certain level in the pipe and in the chamber alike, which level is determined by the equilibrium of pressures between the water and the air exhausted into the chamber. The pressure of the air overcoming that of the water drives the latter into the column pipe until the water level in the chamber sinks sufficiently to allow of the entrance of the air into the pipe. This is followed by a fall of air pressure in the chamber and the water again rises in the chamber to a certain level, as before. The action is thus intermittent, filling the column pipe alternately with air and water.

Advantages of the Combined System

Another special feature that makes this system superior to the Pohle air lift is the exact measurement of the air and water by the pump, which acts as a meter for both air and water. The combined air-lift-and-pumping system is also superior to direct pumping by air or steam, in two respects: 1. For the same air or steam pressure, water is lifted to a greater height because of the decreased density and weight of the water column, consisting of air and water combined. 2. Since the air expands freely as it rises in the column pipe, its expansive force is wholly utilized in this system. This expansion of the air, as it rises in the column pipe, is illustrated in the accompanying figure, which shows alternate layers of air and water; but, while the thickness of the water layers remains constant, and is shown as 2 ft., the thickness of the air layers increases from 6 ft. at the bottom to 24.37 ft. at the top of the pipe.

In his illustration, Mr. Jones has taken the trouble, estimating on a gage pressure of 50 lb. per sq.in., at sea level (65 lb. absolute), to calculate the exact thickness of each layer of air alternating with a water layer corresponding to 1 lb., or a thickness of $1 \div 0.434 = 2.3$ ft. The result of this calculation showed that, ignoring the friction in the pipe, water would be lifted a height of 655 ft. by a gage pressure of 50 lb. Assuming a discharge of, say 400 gal. per min. through a 5-in. column pipe, the friction of the water flowing through the pipe would reduce this head less than 50 ft., making the actual possible lift, under these conditions, somewhat over 600 ft.

In the usual system of pumping by steam or compressed air, without the assistance of the air lift, a gage pressure of 50 lb. per sq.in. would not elevate the water to exceed 100 ft. in vertical height. As previously stated, for the purposes of the present calculation, a size of pump cylinder and piston speed were assumed such as to give a thickness of water layer, corresponding to each stroke of the pump, of 2.3 ft., which represents a pressure of 1 lb. per sq in. The pressure exerted by the uppermost layer of water, in the column pipe, on the air beneath it would thus be 1-lb. gage, or 16 lb. absolute. Each successive layer downward exerts an additional pressure of 1 lb. on the air beneath, as indicated in the figure. Although the actual distribution of the air in the water, in the column pipe, will vary more or less from this theoretical representation, the effect is the same.

Reference has been made to the utilization, in this system, of the expansive power of the air, which expansion is carried farther here and made more complete than in our best multi-cylinder engines when exhausting against atmospheric pressure. It has long been the ambition of designers of steam engines to accomplish this desideratum, in high-class engines; but it has been found impossible of accomplishment in engines of the reciprocating type. The employment of the air lift in combination with a pumping system, as contemplated by the Jones system, therefore, accomplishes that which has been mechanically impossible in reciprocating engines, and affords the largest possible recovery of energy.

The small amount of air absorbed by the water, in this system, is negligible. Also, the slippage of air past the piston in the air cylinder is counter-balanced by the effect of its later presence in the column pipe. A point of no little importance is the fact that the friction of packing is very much less under the low pressures required in this system. Not only is this true, but less trouble is experienced with leaky joints and valves, under the reduced pressure. In the ordinary system of pumping, a greater thickness of pipe is required in the lower sections of the column, and the pump is generally of heavier build. The combined air-lift and pumping system thus presents many points of superiority over the system in common use.

Another point worthy of mention is the fact that, in case the pump is moved to a lower level, and the head thereby increased against which the pump must operate, a distinct advantage is obtained by arranging a bypass to admit a sufficient quantity of air into the column pipe so as to reduce the head and enable the pump to perform its work under the same gage pressure as was employed at the higher level. The freezing at the exhaust of the air cylinder, so common to pumps operated by compressed air, is entirely avoided when the exhaust of the air cylinder is carried into the air chamber, as in this system.

The Closed System

There is some economy to be derived in the operation of the compressor by adopting what is known as the "Closed System," which is illustrated in the detailed sketch shown in the accompanying figure. In this system a closed tank *T*, made of boiler iron, is set in a space prepared for it in the side of the shaft near the top; but at such distance below the surface as to maintain a static head or air pressure, in the tank, of from 5 to 10 lb. per sq.in. The 5-lb. gage pressure marked in the illustration will elevate the water from the tank to the surface a distance of 10 ft.

In this system, the air and water from the column pipe discharge into the tank near the bottom, the air rising to the upper portion of the tank, where it is drawn off by the compressor. An automatic valve *V*, in the air pipe leading to the compressor, is so arranged that if the tank pressure falls below the required static head, the valve shifts and the compressor draws its supply of air from the atmosphere, by the intake pipe *I*. The static head maintained in the tank forces the water up the discharge pipe to the surface.

The advantage of the closed system is that air is delivered to the compressor under a pressure equal to the static head plus the atmospheric pressure, thereby increasing the efficiency of the compressor. Owing to the absorption of some of the air in the water, the compressor is compelled to take air from the atmosphere to supply this deficiency, but the action is automatic.

A Mammoth Mine Pump

SYNOPSIS—Describes a most ingenious design of pump built for a service of 2500 gal. per minute against a 750 ft. vertical head.

The Scranton Pump Co. recently installed for the Lytle Coal Co., Lytle, Pa., a compound condensing mine pump, considered by engineers to be a most modern and ingenious design.

The conditions under which the pump had to operate were exceptional, and many special mechanical features had to be incorporated to overcome the obstacles. Conditions of service demanded a pump to handle 2500 gal. per minute against a vertical head of 750 ft., with steam pressure ranging from 70 to 110 lb. On account of varying steam pressure, and the fact that 24 hours service was required, it was necessary to use a 30-in. steam cylinder provided with cut-off valves with a patented adjustment

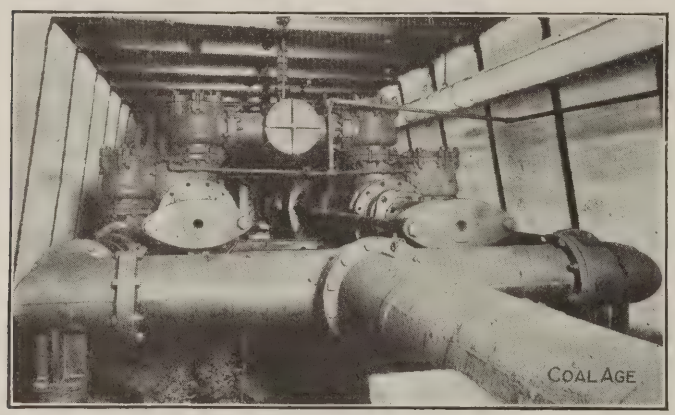


FIG. 1. VIEW OF PUMP ROOM, PUMP AND CONDENSER

which could be set while the pump was operating at its maximum capacity. The low-pressure cylinders are 50 in. in diameter with 14-in. diameter plungers and 48-in. stroke. Owing to the 24 hours service demanded of pump, all parts where possible were made interchangeable; through bolts were used in the water end, and special features were installed so as to make all necessary repairs in the shortest possible time.

The high- and low-pressure cylinders are connected in a manner to allow new piston rings to be placed on high- or low-pressure pistons without taking pistons off rods, or dismantling cylinders.

UNIQUE VALVE DESIGN

The water valves are of the double-beat type with valve seats of special bronze and valves of leather securely locked between two bronze plates. See section of valve chamber and valve, Fig. 2. The object of this design is to secure the greatest valve area with the minimum lift, thus permitting the pump to operate at maximum speed without undue pounding and excessive wear on valve and seat.

Entire water end of pump was wood lined so as to protect the cast iron from the action of the acidulous water.

The valves on steam end were located on the under side of steam cylinders, allowing complete drainage of condensation, or entrained water from the high- to low-pressure cylinders and through the exhaust without danger to cylinder heads or pistons. These valves operate in removable cast-iron bushings with milled ports. With this arrangement and the adjustable rods on valve gear,

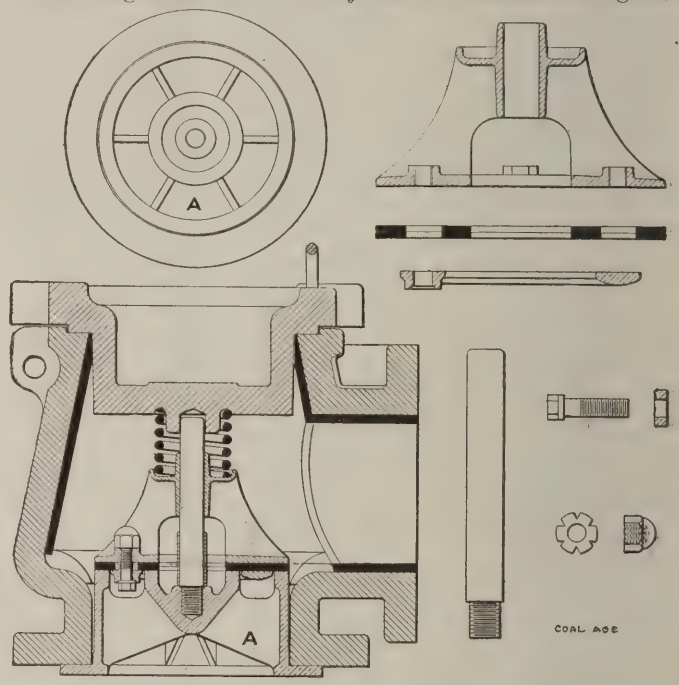

FIG. 2. SECTIONAL DRAWING OF VALVE CHAMBER AND VALVE

an accurate setting of steam valves can be accomplished.

Hand-hole plates were located on low-pressure cylinder heads to allow access to piston-rod nuts without removing the heavy low-pressure cylinder heads.

The cross stands are of the four-bearing type with long bronze bushed bearings and oil pockets of two-quart capacity, affording practically automatic lubrication of rockershafts.

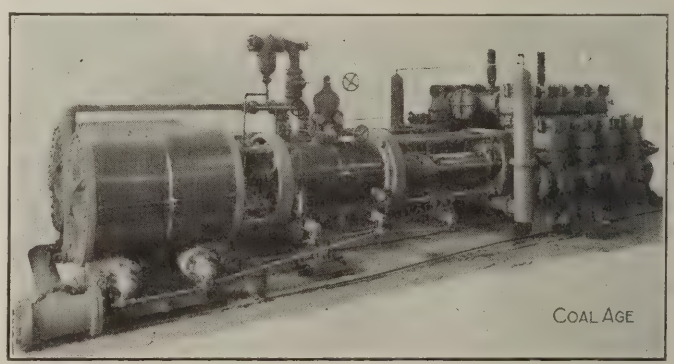

FIG. 3. A MAMMOTH, COMPOUND, CONDENSING MINE PUMP

This machine weighed 90 tons, and an idea of its size can be determined from the fact that it required a pump room 22 ft. wide, 65 ft. long, and 13 ft. high to accomodate pump and condenser.

The exhaust from low-pressure cylinders is taken care of by a single-cylinder independent air pump and jet condenser of the most improved type. Steam cylinder is 14 in. in diameter, air piston, 20 in. in diameter, and all of 24-in. stroke.

The steam end was arranged with special valve gear; the auxiliary slide valve of the "V" type, which insures against the valve not seating, and a double-ported steam chest to admit steam to chest piston, which in turn operates the main slide valve. This construction allows the proper cushion for chest piston and prevents slide valve from overtravel, thus absolutely guaranteeing full stroke and continuous operation of condenser. The air end was of the sectional type, special for mine work so as to reduce repair expense, and save considerable time in replacing worn-out parts.

The air piston was of special bronze and arranged with a soft-rubber ring next to packing. This construction automatically takes up wear on packing and reduces the friction of packing on liner to an extent that the life of the packing and bronze liner is doubled.

The Principle of the Centrifugal Pump

By J. D. Cone*

SYNOPSIS—The modern centrifugal pump can be made to perform practically any pumping duty common to coal mining. Its peculiar advantages are: simplicity, low-maintenance cost and its ready connection to the high-speed motor and steam turbine.

The advent of the high-head, high-efficiency centrifugal pump within the last 10 years has naturally resulted in considerable literature on the subject. The books available are of interest to the scientist, of some little value to the engineering student, but practically useless to all others. There are many practical men who have to buy, install or operate centrifugal pumps, who would like to go into the theory of the matter to some extent without being utterly befogged by a thick haze of higher mathematics. It is to these that I address my remarks and trust that within the limits of a brief magazine article, I can make quite clear the principles surrounding the operation of, what is after all, a very simple device.

*New York.

A pump is a machine for transferring a fluid from one level to a higher level, or for increasing the pressure of a liquid. Both processes being, of course, the same, may, therefore, be performed with the same device, and simultaneously, if necessary.

A centrifugal pump, so called, is a device that uses centrifugal force to accomplish the above ends. Fig. 1 shows a cross-section of a Cameron two-stage centrifugal pump. The essential parts are the shaft *A*, revolved by some external force; the impellers *B*, secured to the shaft and therefore revolved with it; and the casing *C*, in which both these parts operate. All the other parts are details and can be disregarded in the discussion of the principle of operation.

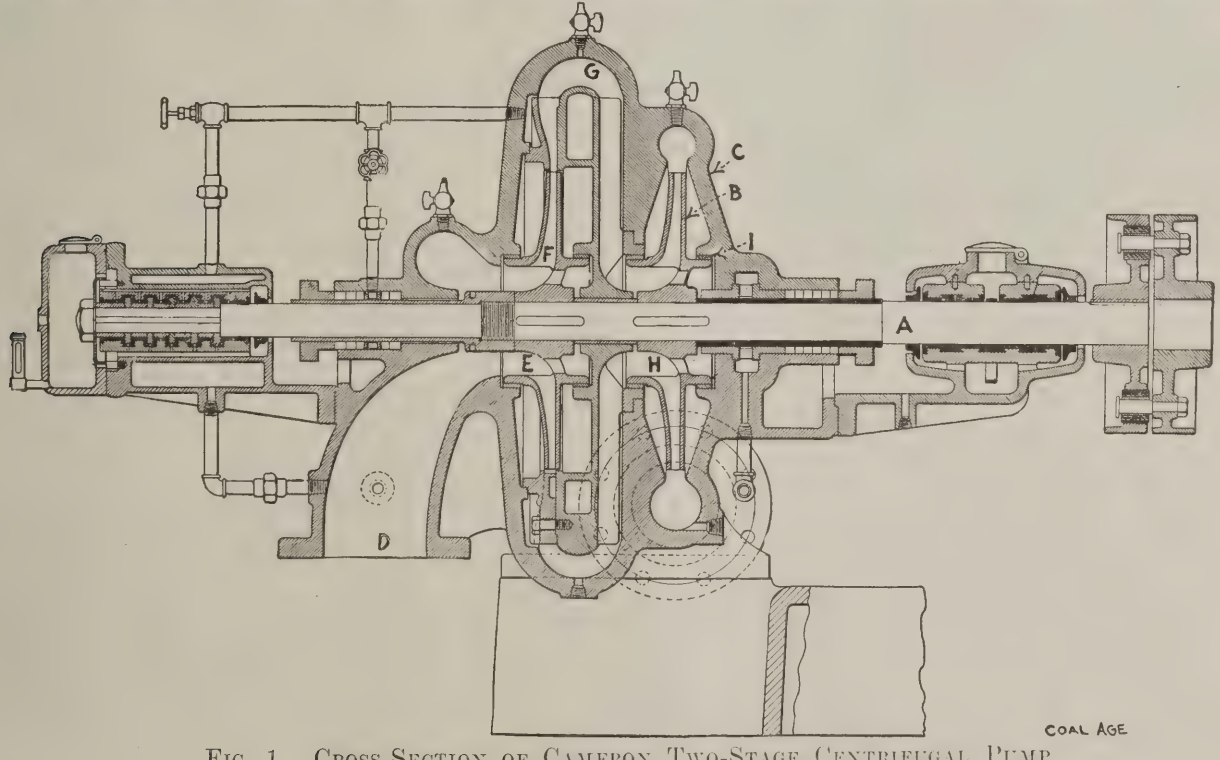

Fig. 1. Cross-Section of Cameron Two-Stage Centrifugal Pump

Water enters the pump at point *D*, called the suction inlet, and passes to the impeller, entering at points *E*. The impeller has curved radial passages *F*, leading from the hub to the periphery. As soon as the water enters the impeller, which is revolving at high speed, the centrifugal force available tends to increase the pressure of the water, and the increment is continuous until the water reaches the periphery of the impeller where cen-

trifugal force ceases to operate and the pressure is no longer increased through the action of this agency.

If water is allowed to pass continuously through the pump, the water in the impeller (being already under pressure) will be thrown off at a velocity dependent upon the peripheral velocity of the impeller. The water then exists under pressure and with a certain velocity. To be of use, this velocity energy must be converted into pressure energy and thus augment the pressure already produced by centrifugal force. This transformation of energy takes place after the water has left the impeller, the efficiency of the pump being largely dependent on the amount of loss that takes place during the change.

Velocity Energy Is Converted into Pressure Energy

In the particular design which we are discussing, this conversion is accomplished efficiently by the use of what is called a diffusion ring. This is a ring entirely surrounding the periphery of the impeller and having at regular intervals a series of enlarging passages. These

Fig. 2. Showing Diffusion Ring

passages are quite small at the inner diameter and rapidly increase in area toward the external diameter; see Fig. 2. Water flows into the small end of these passages and, as the area rapidly increases, the velocity of the water is cut down proportionately and no appreciable work being done, the energy contained as velocity must appear in some other form, and does so as pressure.

The coöperation of the two forces above described is clearly shown by the use of the parallelogram of velocities given in Fig. 3. The line *CF* represents the velocity, and the relative direction of the water flowing through the impeller, the direction, of course, being that of the tip of the impeller vane. The line *PV* represents the velocity of the tip of the vane, and is, of course, tangential in direction.

Now, if we compound these two lines, we will get the intermediate line *AV*, which represents the actual velocity and direction of the water leaving the impeller. Then, by a very simple formula, the designer can conclude from the velocity just what pressure the pump can generate, or working backwards, as is usually the case, can design the machine to give certain definite results.

The pump shown in Fig. 1 is a two-stage machine, i.e., it is equipped with two impellers operating in series, the discharge from the first impeller leading through passages *G* into the suction *H* of the second, where the initial process is repeated and another increment of pressure obtained. By this construction practically any reasonable pressure can be secured, and pumps made in eight, ten or even twelve stages are not uncommon. It is usual to limit the pressure obtained in any one stage to about 90 lb.; and if a higher pressure is desired, add other stages.

What Is Meant by "Thrust"?

No discussion of the centrifugal pump would be complete without some mention of thrust. Thrust is manifested, of course, in all centrifugal pumps. It is caused by unavoidable unbalanced areas at some point inside the pump and it operates to force the running parts violently to one side or the other, resulting in heating, wear and loss of efficiency, unless adequate means are provided to take care of it.

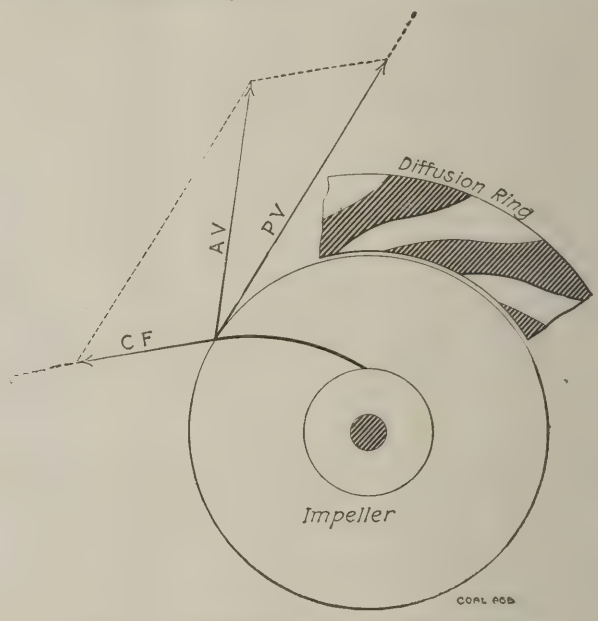

Fig. 3. Parallelogram of Velocities

In the particular pump under discussion, water enters *D* at atmospheric pressure (or less if water is being lifted), and the left-hand side of the impeller within the area of the rings *I* is, of course, under the same pressure. Now, the right-hand side of the same impeller is in more or less communication with the discharge pressure through the leakage which takes place past the wearing rings *I* (some leakage must be allowed here for lubrication), and is therefore practically subjected to the pressure generated in the first stage. This greater pressure on the right-hand side of the impeller acts toward the left and sets up thrust in a direction opposed to the direction of the incoming water.

To take care of this thrust it is usual to supply a marine thrust bearing, and the Cameron pump is so equipped. This is clearly shown at the left-hand end of the shaft. The thrust bearing consists of a series of babbit-lined grooves in a stationary cast-iron shell. In these grooves corresponding steel collars fit. They are mounted on and revolve with the shaft. It will readily be seen that this arrangement provides a series of shoulders which resist lateral movement, maintain the alignment of the impeller, and absorb any tendency to thrust.

Finally, a word as to efficiencies: As in all apparatus, efficiency is the ratio of output to input, and in the par-

ticular case of the centrifugal pump it is the ratio of water-horsepower, as represented by the discharge pressure and capacity, to the brake horsepower supplied to the pump shaft. This is known as pump efficiency. Sometimes overall efficiency is mentioned, and this comprehends the losses in the motive power also. In the case of an electrically driven pump, the overall efficiency would be the ratio of the water output to the watts delivered to the motor, both quantities, of course, being reduced to foot-pounds for purposes of comparison.

Efficiency of Pumps

The efficiencies of the better class of pumps will run from 45 to 75 per cent., depending upon the size of the machine and the particular conditions under which the pump is to work. As a general rule, the high-head, high-speed, large-capacity pump will give the best efficiency.

In a pump having 70 per cent. efficiency, there will of course be 30 per cent. of losses, and these losses will be divided about as follows: Mechanical friction, 5 per cent.; hydraulic friction, 10 per cent.; leakage past the wearing rings, 5 per cent.; eddy currents or whirlpools, 10 per cent.

The field for the centrifugal pump is extending continually. There is hardly any pumping duty that cannot be performed efficiently by this splendid device, with its great simplicity, low maintenance cost, and ready connection to the high-speed motor and steam turbine.

We may expect within the next few years as the art of centrifugal-pump building advances to still further reduce the losses mentioned, thereby attaining still higher efficiencies.

Mining Suspension Opens with Large Stocks on Hand

Just previous to the suspension in 1912, Coal Age reported market conditions as follows:

The tense feeling in the coal market continues unchanged. Consumers and producers are both keenly watching the results of the wage conferences, many of the larger interests having special representatives on the ground to insure reliable and prompt reports on the situation. It is purely a strike market and has been accepted as such by the trade, which is now playing a waiting game.

The movement to the Eastern markets continues to be only sufficient to meet current demands, and none of the companies are accumulating any surpluses. Prices are at the same high level, although they vary considerably with the reports on the labor situation. Water freights are somewhat lower and the railroad congestion is rapidly improving. In the Pittsburgh steam markets there is a disposition on the part of the consumers to shut down their plants rather than buy at the prevailing high prices.

In contrast with which the situation last week, Mar. 28, was reported as follows:

The coal year is closing with current business in anthracite at a complete standstill but a marked activity on negotiations for the new year.

On the eve of what appears to be a certain suspension in the principal bituminous coal districts of the country, the market continues relatively dull and listless. Some last-minute business has developed, causing a slight stiffening in prices, but, on the whole, the trade is far from what would normally be expected at this time. There is little confidence in the possibility of a long suspension and consumers seem to be well stocked for any emergency that may arise.

In Ohio, consumers, as a rule, refuse to be influenced by the possibility of a suspension, while the warm weather has caused a lull in the domestic business and dealers are endeavoring to clean up stocks rather than accumulate supplies. The railroads are beginning to accept lake coal, which may relieve the pressure.

The spot demand at Hampton Roads is light, the movement being confined almost entirely to contract; other West Virginia coals are dull and heavy, in spite of the near approach of the lake shipping season.

The general indifference of consumers to the possibility of a serious strike has created a great deal of uncertainty in the Middle Western markets. There has been some stocking, particularly on the part of the railroads, which has developed a hardening tendency in the market, but this is not by any means of notable proportions.

New Mine-Rescue Station

A station for mine-rescue car No. 4 of the government has been completed at Pittsburg, Kan., recently. The State of Kansas appropriated $3500 for the structure. It contains trackage for the car and rooms for the men in charge, and possibly office room for State Mine Inspector Francis Keegan and his force of deputies.

New Rescue Station at Pittsburg, Kansas

A spur of the Santa Fé R.R. enters the building. Much effort was expended in getting this edifice. It is in the center of the southeastern Kansas coal district and is only about 25 miles from the heart of the Joplin mineral district. Railroad facilities are excellent, the Frisco, the Missouri Pacific and the Kansas City Southern roads being ready with engines almost instantly to take the car out.

Acetylene Lamps in Blackdamp

By John Morris

Considerable interest has been aroused by Doctor Harger's proposal to charge the ventilating current of a mine with carbon dioxide as a means of preventing explosions. I have unfortunately had an experience of working in blackdamp with the aid of acetylene lamps, which in some respects goes far to prove the correctness of some of Doctor Harger's conclusions.

The adit level was the return airway of the colliery and also the drainage level, with the result that a considerable quantity of water ran through it. A fall occurred about 700 yd. from its mouth which banked up the water and completely stopped the ventilation. There was a small shaft about 250 yd. from the mouth of the adit level, the distance from this shaft to the fall being about 450 yd. It was found impossible to carry ordinary naked lights nearer than about 100 yd. from the fall, but an acetylene lamp would burn without trouble.

Note—Excerpt from paper on "Notes on Gobfires and Blackdamp," presented at meeting of the North of England Institute of Mining and Mechanical Engineers, Feb. 14, 1914.

After it had been made certain that the blackdamp had no appreciable effect on the men, several workmen using acetylene lamps were sent in to clear away the fall and work proceeded without interruption in relays. The blackdamp gradually gained until after the second day, a naked light was extinguished five yards inside the small shaft, but the gas appeared to have no ill effects upon the men, although they had to walk over a quarter mile to the fall through an atmosphere in which a match could not be struck. The acetylene lamps also burned as well as ever; and the men were able to work an 8-hr. shift.

The atmosphere gradually became worse until on the fifth day the acetylene lamps burned very dimly and even when a large flame was produced gave out very little light. At this stage some of the men complained of headache, although others did not feel any inconvenience, but all breathed heavily.

The Lamps Burned Dimly and Men Suffered from Headache

Later on, the acetylene lamps began to go out, although placed so as to be quite steady and most of the men suffered from headache and smarting of the eyes, talked rather thickly, were somewhat unsteady and could not do any hard work. So long, however, as the acetylene lamps continued to burn at all, the men were quite capable of looking after themselves.

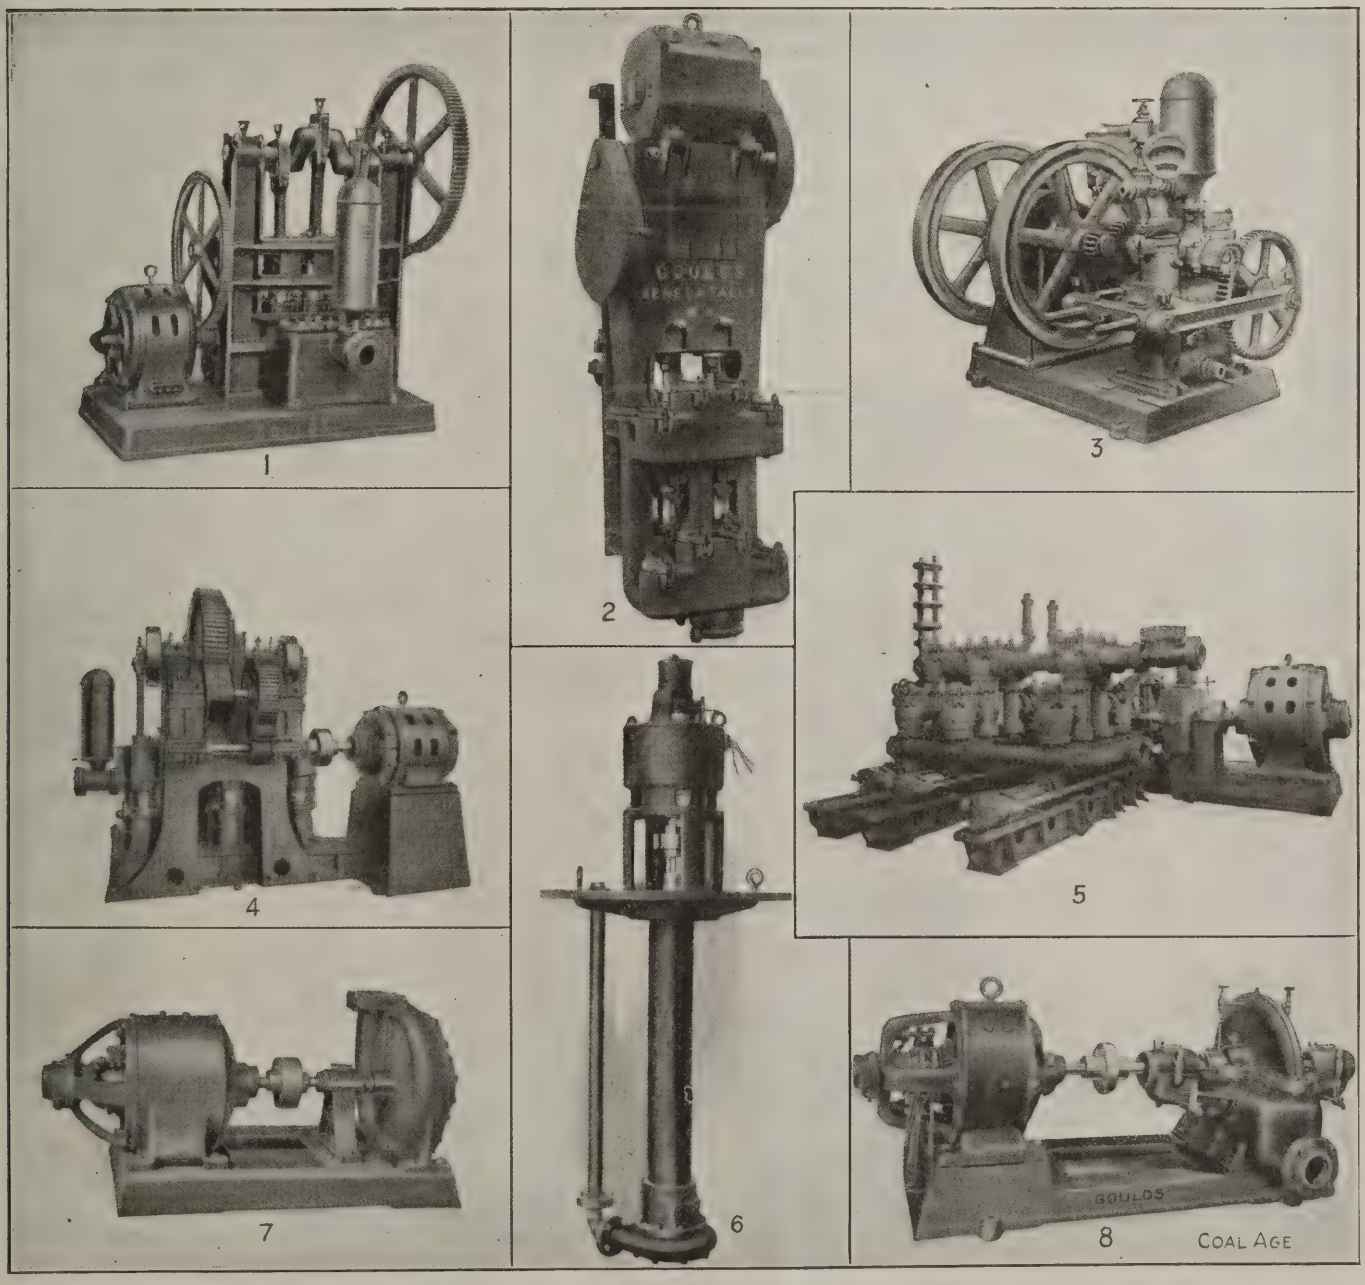
At this stage, it was interesting to watch the behavior of the acetylene lamps; even when increased in size the flame, which had a bluish color, gave very little light, it stood at some distance, perhaps 2 in. above the burner, went up and down, and seemed to hunt about for air before it finally went out. Even at this extreme stage I did not feel much ill effect with the exception of a slight headache, smarting of the eyes, and a little deafness.

Blackdamp Caused Deafness and Lack of Control over Limbs

Although the atmosphere was now such that the acetylene lamps would not burn,* I remained for about half an hour in the blackdamp in order to find out what the effects would be. Deafness became more pronounced, my limbs did not seem to respond to the will, and on moving about the legs seemed to go wherever they pleased; this was after five days' almost continuous living in the blackdamp. The ill effects disappeared very soon after getting into fresh air. Gob fires could not possibly exist in the atmosphere prevailing at this period, and explosions certainly could not happen, even if firedamp had been present. This experience goes far to prove Doctor Harger's contention that men can with impunity breathe an atmosphere which will not support combustion. I am firmly of the opinion that men could remain, without danger to themselves, in an atmosphere charged with blackdamp so long as acetylene lamps continued to burn.

*According to Dr. Harger, an acetylene lamp will go out when the percentage of oxygen left in the air has been reduced to 9.5. "Trans.," Inst. M. E., 1912, Vol. xliii, p. 132.

Why Not Work on the Flock Instead of on Just Two or Three?



The Development of Modern Types of Mine Pumps

SYNOPSIS—Some notes on the gradual evolution of the modern drainage engine and a pictorial description of the different types.

One of the earliest attempts to unwater mines by means of power-operated pumps was made by Newcomen, in 1705. His was a simple bucket type of pump, connected by means of a long rod, to the walking beam of the Newcomen atmospheric engine. The subsequent invention of the steam engine by Watt lead to the development of the "Cornish" type of pump, consisting of a simple bucket, or plunger pump operated by the crank disk on the engine shaft. The "Cornish" pump was fairly efficient when the pump cylinder could be placed directly under the engine, but when the mine workings extended in various directions from the original location of the engine the water ends were operated by means of long rods through bell cranks and the added friction of these working parts resulted in low efficiencies.

About 1860, the direct-connected steam pump was placed upon the market and being compact and easily moved from one mine to another, it was adopted almost universally. The steam boilers were, of course, on the surface and the long steam pipes, sometimes over 2000 ft. long, occasioned great loss of power. The heat of these pipes and the difficulty of disposing of the exhaust was another serious objection to this style of pump.

In the early '90's a new design of pump was brought out, known as the triplex power pump, driven by an electric motor. The compactness, simplicity and efficiency

Different Types of Modern Pumps Used in Coal-Mining Service

of this unit commanded instant recognition, particularly in the mining districts where the majority of the more important mines adopted it. The power pump requires from 50 to 75 per cent. less fuel than the direct-acting steam pump and its general use has been a big factor in the reduction of operating costs. During the past four or five years, centrifugal pumps have been designed, showing good efficiencies and their use in coal mines is becoming quite common, particularly in West Virginia and the Western fields.

Electrical-operated pumps have been designed to meet every condition in mines and a general description of the more common types are given herewith.

Types of Pumps

Fig. 1 shows a single-acting triplex portable mine pump, designed for pumping sumps and general emergency service. The capacities vary from 50 to 300 gal. per min. and it will pump against elevations of from 300 to 500 feet.

Fig. 2 shows a duplex, double-acting sinking pump. It is designed to be lowered in the shaft to pump from the bottom of the mine to the surface or to a station.

Fig. 3 shows a single-cylinder, double-acting piston pump operated by a gasoline engine. It is built for capacities up to 100 gal. and for heads of 175 ft. It is light and portable and is used generally in the anthracite mines around Scranton, Pennsylvania.

Fig. 4 illustrates a motor-driven, single-acting triplex plunger pump, built for capacities up to 350 gal. per min. and heads up to 400 ft. This style of pump is used in small stations and also for boiler feed.

Fig. 5 shows a typical station pump. These are designed for capacities up to 2000 gal. per min. and heads up to 5000 ft. They are built primarily for mine service and the largest part of any of these pumps will go down in a shaft 3 ft. 6 in. square.

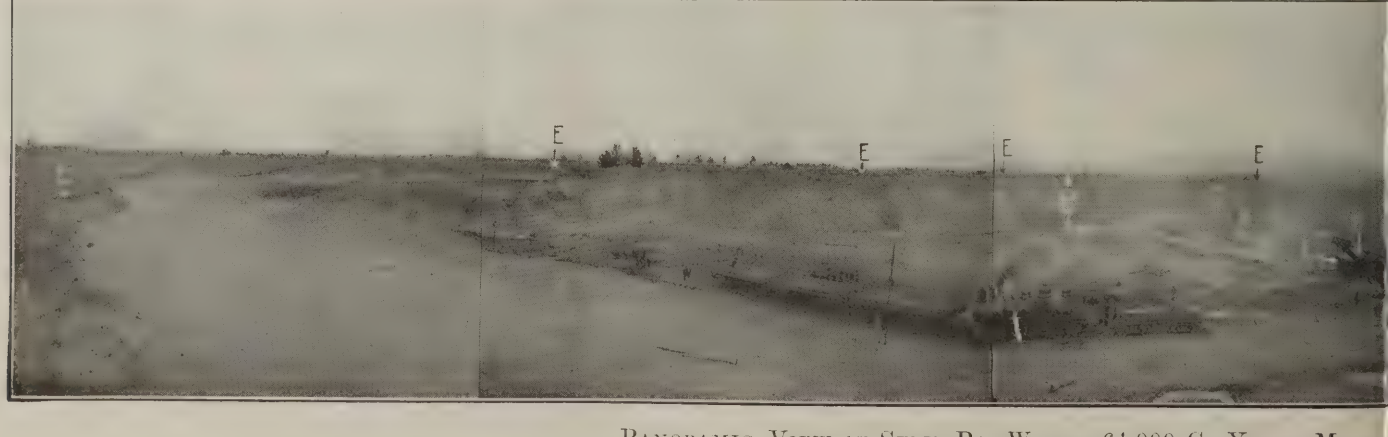
Fig. 6 illustrates a vertical centrifugal sump pump. Its capacities vary from 40 to 50 gal. per min., against from 40- to 50-ft. head.

Fig. 7 shows a motor-driven single-stage side-suction pump, with capacities from 40 to 200 gal., against an elevation of 100 ft. This style of pump has an impeller and is particularly adapted for handling dirty and gritty water.

Fig. 8 shows a motor-driven single-stage double-suction pump, built for capacities from 100 to 7200 gal. per min., against 150-ft. head.

Stripping a Mine by Hydraulic Methods

By P. J. McAuliffe*



SYNOPSIS—Where the overburden is exceptionally tenacious, the steam-shovel method of stripping a mine is impractical. Under such conditions, a hydraulic plant, consisting of a water pump, hydraulic giant and sand pump, has been substituted with remarkable success and small expense.

At the Rowe mine, at Riverton, Minn., in a district where stripping by means of steam shovels has reached the high-water mark of efficiency, a hydraulic plant for removing the overburden has been installed and operated for a season with remarkable success, equalling, if not surpassing, the very best results of the steam shovels.

The material comprising the overburden, which averages about 54 ft. in depth, consists of sand, gravel and a gumbo clay, which is excessively sticky and tenacious; so much so that, after several attempts to handle it, steam shovels had to be abandoned, as, not only would the track work down out of sight under the shovels, but also at the dump. Even when the cars were lined with 2 ft. of straw the clay often would pull them down the dump with it, or else refuse to leave them at all unless pried loose and shoveled out.

The mine is adjacent to Little Rabbitt Lake, where the water pump, with a capacity of 3500 gal. per min., is placed. The water is pumped through about 1500 ft. of 12-in. pipe to the point chosen for excavation. Here the pipe is reduced and an ordinary hydraulic giant is fitted. The size of the giant nozzle is varied for the different ma-

*Morris Machine Works, Baldwinsville, N. Y.

Panoramic View of Strip-Pit Where 64,000 Cu.Yd. of Mate

terials encountered, but for the average work a 4-in. nozzle is used. The water pressure at the nozzle is about 50 lb. The stream is directed against the bank and the material is washed down a rough channel to where a 12-in. Morris sand pump is located. The suction of the sand pump picks up this water and material and pumps it out through 12-in. pipe to the spoil bank. The discharge pipe of the sand pump varies in length during the season's work from 500 ft. to 1300 ft., with an average of about 1100 ft. The vertical distance from where the sand pump picks up its material to where it deposits it on the spoil bank is 27 feet.

It was found that the material brought down by the hydraulic giant would wash down to the sand pump on a grade as flat as 4 ft. in 100 ft. In other words, the sand pump could be permanently located in one place on a flat-boat or heavy skids while the giant could be worked all around the pump in a gradually increasing circle until this 4 in 100 slope ran out. In the above mentioned average depth of 54 ft., this limit would not be reached until the giant had swept a circle around the pump of 1350 ft. radius.

Compared to the constant moving of cars and tracks for a steam-shovel outfit, this is quite a saving. In all last season's work the location of the sand pump did not have to be changed.

Both pumps were driven by electric motors, the water pump being geared to motor and the sand pump being belt-driven.

This outfit handled on an average of 51,000 cu.yd. of material per month for the season's work, at a cost ranging from 5½c. to 7c. per cu.yd. This cost covers labor, operating expenses, upkeep and office expenses. The best month's performance was in December, when 64,000 cu.yd. were moved in 617 working hours with an average of 103.7 cu.yd. per hour.

The accompanying picture shows a panoramic view of the operation. The entire pit was excavated in five months by the above described plant. The steam shovel shown in picture made the excavation where the tracks are laid only. Here the orebody is reached and the steam shovel is necessary.

This hydraulic method of stripping has been so satisfactory to the mine owners that they have ordered two complete new outfits for the coming season's work. The new sand pumps are made of steel with all parts of extra-heavy proportions. They were built by the Morris Machine Works, of Baldwinsville, N. Y. Before the coming season has passed the mine owners expect to have these sand pumps discharging through 2400 ft. of pipe against a 50-ft. static head.

List of Permitted Explosives, Canada

The list of explosives given below in the First Schedule is a complete table of the permitted explosives that have passed the new Rotherham test.

After Mar. 15, 1914, no explosives except those specified in the following schedules may be used or taken, for the purpose of use, into any mine in which the use of permitted explosives is required by the Explosives in Coal Mines Order of Sept. 1, 1913.

The use of the explosive named in the Second Schedule is permitted only for five years from Jan. 1, 1914, for the purpose of bringing down coal, in the class of mines defined in Clause 11 of the said order.

FIRST SCHEDULE

Explosive	Permissible Maximum Charge in Oz.	Pendulum Swing in In.*
Ajax powder	12	2.69

Bobbinite

* This is the swing given to the ballistic pendulum, at the Home Office Testing Station, by firing at it a shot of 4 oz. of the explosive. It may be compared with the swing of 3.27 in. given by a shot of 4 oz. of gelignite containing 60 per cent. of nitroglycerin.

Was Handled in One Month by Employing a Hydraulic Plant

Electric Pumping at Tilmanstone Colliery*

SYNOPSIS—A detailed discussion of the construction, installation and operation of the electric pumping plant in use at the Tilmanstone Colliery, Dover, England; with an appended set of instructions for the switchboard and sinking-pump attendants.

The coal measures at Tilmanstone are directly overlaid by a sand bed 20 ft. thick, the latter being met with at a depth of 1150 ft., and proving to be heavily watered. It was decided to install three horizontal-type steam pumps, each having a capacity of 500 gal. per min., the water being admitted to the pump chambers through a series of boreholes, and the flow being controlled by a valve fitted to a safety-boring device.

The writer designed this safety-boring apparatus (Fig. 1), which consists of two tubes, sliding one within another, the lower ends being fitted with flanges turning outwards. By a series of india-rubber washers a water-tight joint is obtained. The upper end of the tubing is provided with a side tap and a through-way valve. The diameter of the borehole, to admit a 2½-in. bore-tube, was 4½ in., and this larger borehole was made specially for the reception of the boring apparatus. The boring apparatus was tested hydraulically to a pressure of 500 lb. per sq.in. Eventually, it was found that the volume of the feeder exceeded the capacity of the pumps installed, when it was decided to install electrically-operated pumps.

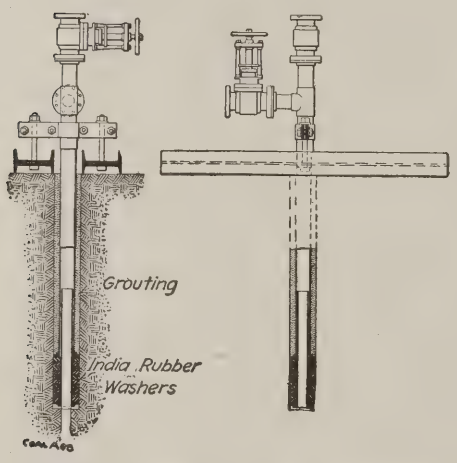

Fig. 1. Safety Boring Apparatus Used at Tilmanstone Colliery

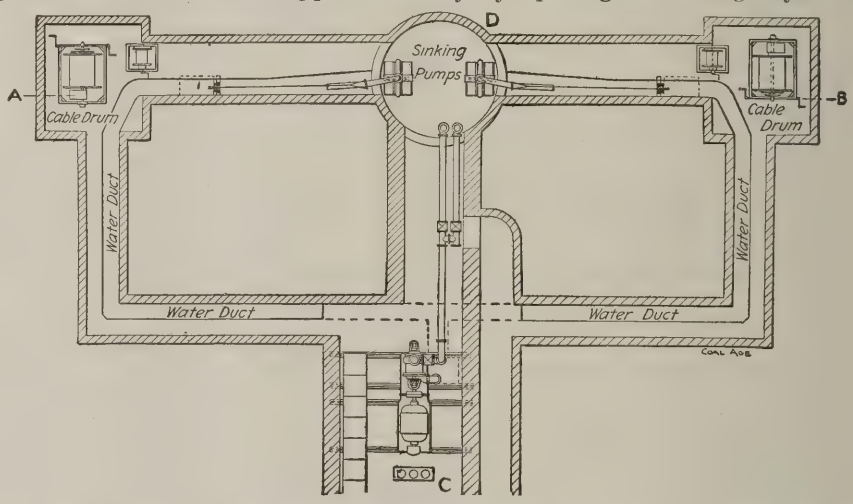

Fig. 2. General Arrangement of Electric Pumping Plant at the 600-Ft. Inset

Figs. 2, 3 and 4 show the arrangements adopted for unwatering the shafts. A pump, inset with suitable waterway-ways and cable-ducts, was made at the 600-ft. level, and in it was installed a horizontal stationary Sulzer pump, direct-coupled to an A. E. G. three-phase-motor wound for 3000 volts, 50 periods. Two sinking pumps were suspended in the shaft on steel-wire ropes. The control of the fixed horizontal pump, and of two sinking-pumps, was carried out from a switchboard, mounted in the 600-ft. pump-room, the switchboard consisting of 10 switch pillars built of sheet steel and totally enclosed.

Each sinking-pump motor was started by its own transformer, contained in a separate pillar, the adjoining pillar being provided with an oil switch, isolating lines and instrument transformers. The oil switch was also fitted with overload and no-volt releases (the latter being interlocked with the starting transformer), and further with an emergency stopping switch fixed on the frame of the sinking pump. Owing to these interlocking connections, it was impossible to close the motor oil switch unless the starting transformer was in the starting position, but in case of emergency, the motor could be stopped instantly by opening the emergency switch, fixed on the frame of the sinking pump. The breaking of the emergency switch trips the oil switch on the pump-room switchboard.

The cables for the sinking-pump motors were carried from the switchboard along the water ducts to the cable drums, connection to the latter being made through slip-rings mounted on the cable-drum shafts. The pilot cable, for stopping either sinking-pump motor, was also carried in a similar manner to a cable drum (see Figs. 2 and 3). The cable drums have steel-plate sides and laggings, and are mounted on shafts carried by strong angle-iron frames. Current was led through slip-rings fixed to the drum shaft, the slip-rings being totally enclosed in a cast-iron case. The high-tension sinking-pump cables were of the three-core rubber insulated and double steel-wire armoured type, each core having a sectional area of $\frac{1}{10}$ sq.in. The armouring consisted of specially fine steel wire to render the cable thoroughly flexible. Each cable was connected to the pump motor by a suitable water-tight cable and box, the end of the cable being brought up from below with a view to preventing moisture finding its way into the cable box. Support for both the main and pilot cables was provided by clamps resting on, and bolted to, the main clamps, carry-

*From paper by Henry J. Wroe, presented at meeting of the London branch of the Association of Mining and Electrical Engineers, on Feb. 6, 1914. The Tilmanstone Colliery, of which Mr. Wroe is the manager, is owned by the East Kent Colliery Co., Ltd., and is situated at Eythorne, Dover, employing about 250 workmen.

ing the pipe column (see Fig. 5). A special feature of the clamp is the provision for liberating the cables without the necessity for removing the main-pipe clamps, and this arrangement proved a great advantage on several occasions.

The two sinking pumps, supplied by Mepis Sulzer Brothers, were of the centrifugal type arranged with vertical spindles. Each was capable of delivering 1200 gal. of water per min. against a maximum manometric head of 870 ft., with four impellers. An injector operated by water from the delivery column was connected with the top of the pump casing from which is evacuated any air taken in by the pump should be the latter be working "on snore." The oil wells for the bearings of the pumps and motors were water-jacketed, the water being taken from the first stage of the pump. Each sinking pump was coupled by means of an elastic coupling to a totally-enclosed three-phase squirrel-cage motor, each motor being capable of developing at 3000 volts, 50 cycles, a continuous output of 500 b.hp. at a synchronous speed of 1500 r.p.m. The upper bearing of the motor carried the weight of the rotor, the weight of the pump shaft and impelled being taken by a step bearing on the pump.

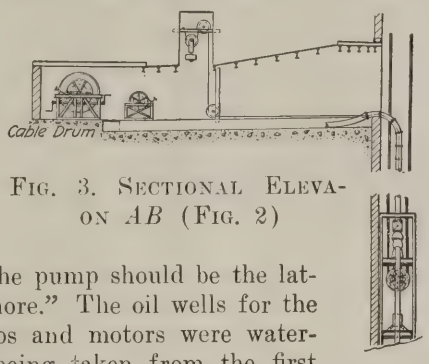

FIG. 3. SECTIONAL ELEVATION *AB* (FIG. 2)

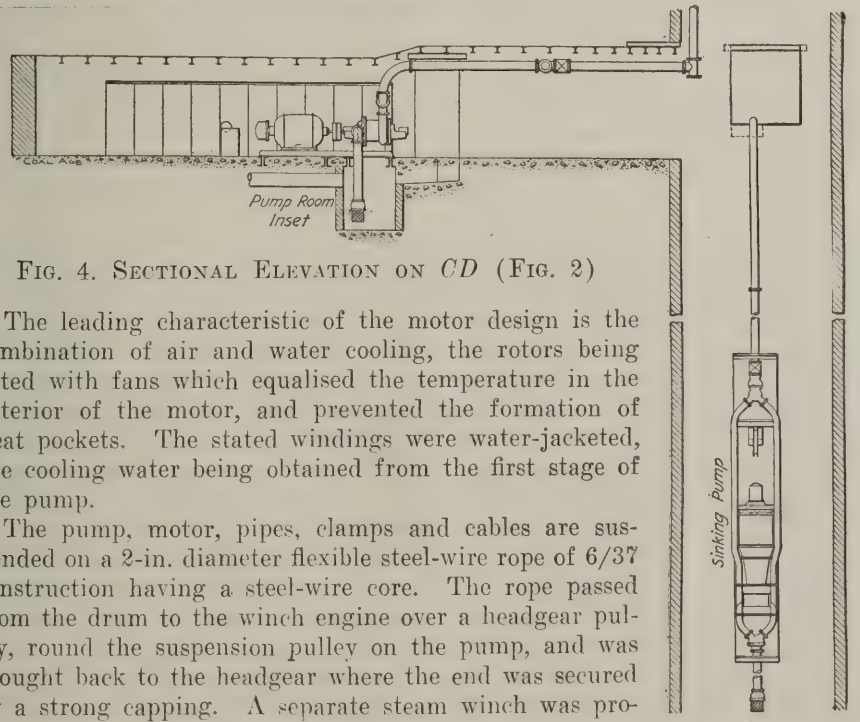

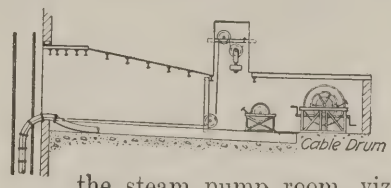

FIG. 4. SECTIONAL ELEVATION ON *CD* (FIG. 2)

The leading characteristic of the motor design is the combination of air and water cooling, the rotors being fitted with fans which equalised the temperature in the interior of the motor, and prevented the formation of heat pockets. The stated windings were water-jacketed, the cooling water being obtained from the first stage of the pump.

The pump, motor, pipes, clamps and cables are suspended on a 2-in. diameter flexible steel-wire rope of 6/37 construction having a steel-wire core. The rope passed from the drum to the winch engine over a headgear pulley, round the suspension pulley on the pump, and was brought back to the headgear where the end was secured by a strong capping. A separate steam winch was provided for each pump, each winch being capable of handling 40 tons (single purchase). Owing to the short lead of the ropes and to the heavy weight to be handled (the final load on each winch being 50 tons), it became necessary to make a traversing arrangement in order to prevent the ropes "copying" on the drum. This traversing gear is shown in Fig. 7. It consists of a massive cast-iron nut, carrying two rollers, the nut being moved to and fro by a strong screw operated by hand wheels, the rope passing between the rollers. In order to facilitate the pipe-changing, two steam winches were fixed at bank, and these lowered the delivery pipes to the 600-ft. level, where they were added to the pipe columns as required. To counterbalance the weight, and to facilitate the taking-in of the hose pipe when a further length of steel piping was about to be put on, it was secured to a wire rope which passed round a series of pulleys, the inbye end of the rope being weighted, as shown in Fig. 3.

PUMPS AT 1140-FT. INSET

A new pump inset was made from No. 3 Pit at the same level as the steam pump room, viz: 1140 ft., and three electric pumps together with suitable switchgear were installed, as shown in Fig. 6. Each pump is of the horizontal stationary six-stage type, rated for a normal delivery of 1000 gal. of water per min. against a manometric head of 1300 ft. The guaranteed efficiency is 73 per cent. All those parts which are liable to excessive wear, such as packing rings and packing bushes, are easily replaceable. These rings and bushes as well as the complete balancing device are made of hard bronze, the latter being armoured by hardened steel rings.

Each pump is mounted on a common bed plate, and is coupled direct by means of an elastic coupling to a three-phase-motor of the ventilated-enclosed type, capable of

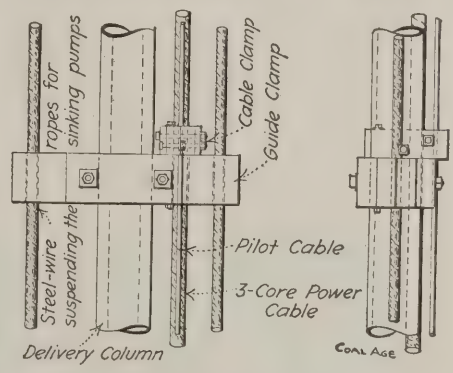

FIG. 5. GUIDE CLAMP AND CABLE-SUSPENDING CLAMP FOR SINKING PUMPS

developing at 300 volts, 50 cycles, a continuous output of 680 b.hp. at a synchronous speed of 1500 r.p.m. The roter has slip rings and brush raising and short circuiting gear. The motor is started by means of a liquid-starter provided with separately mounted protective resistances. The bearings of pumps and motors are ring-lubricated, the bearings being water cooled.

Each pump is connected to the delivery piping through two valves arranged in series, one being the master valve which is always open, the other the gate valve used for controlling the pump-discharge. The foot valves are protected from excessive pressure by a device consisting of two flanges, between which is placed a thin piece of India rubber sheeting. The flanges are fitted to a short piece of tubing connected with the suction piping, and

if, for any reason, the pressure from the column comes on to the foot valve the india-rubber disc between the two flanges is broken before any further damage can be done. The pressure at the base of the delivery column is 520 lb. per sq.in. and it will be obvious that, should this pressure come on to the foot valve, damage either to the valve or to the flange on the suction side of the pump might result. The switchboard consists of three feeder panels, three motor panels, one spare motor panel, one transformer panel containing a 150 k.v.a. step-down transformer, and one transformer switch panel.

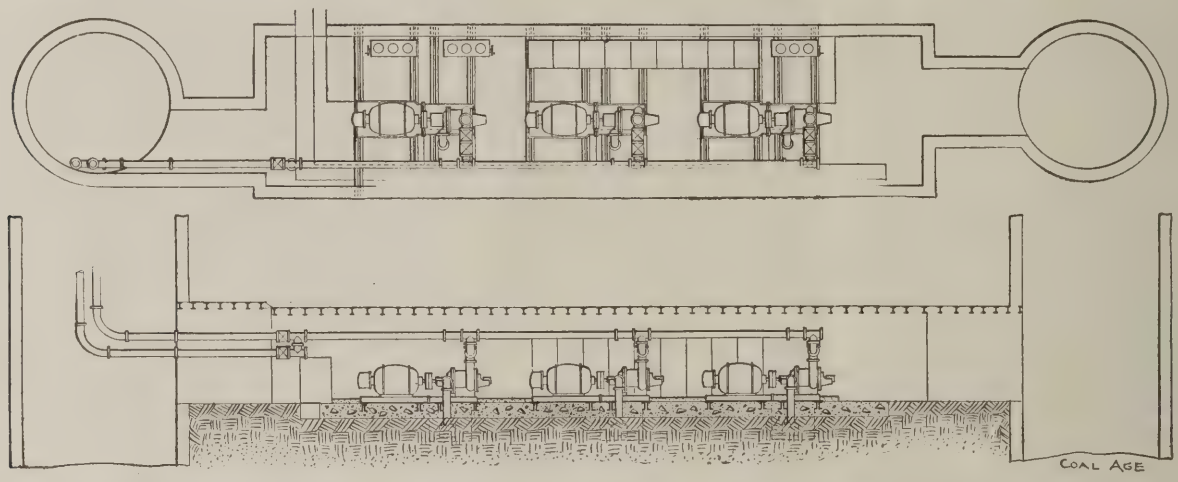

FIG. 6. ARRANGEMENT OF THE ELECTRIC PUMPING PLANT AT THE 1140-FT. INSET

When the coal measures were reached, the water was tubbed out of the shafts, and then the water conditions for the pumps improved very greatly. The quantity of water to be dealt with, has since fallen off very considerably, and arrangements are being made for altering the internal parts of the pumps, so that one pump will easily deal with the whole of the water made at this level. It may be mentioned that during the sinking and unwatering operations, which lasted ten months, not a single stoppage of the electricity supply occurred, and, further, that the sinking pumps and motors, in spite of

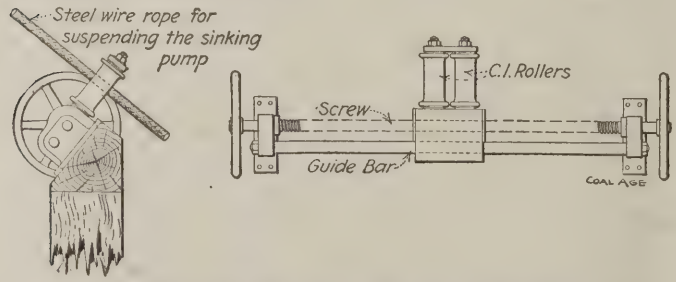

FIG. 7. ARRANGEMENT FOR GUIDING SINKING-PUMP SUSPENSION ROPES ON WINCH DRUMS

the onerous conditions under which they worked, were used alternately in such a way, that pumping was carried on continuously.

With a view to initiating the switchboard and sinking-pump attendants in their duties, and in order to obtain uniformity in the carrying out of the various operations, two sets of rules were drawn up—one for the switchboard attendant at the 600-ft. level, and the other for the use of the sinking-pump attendant. These rules are given in Appendixes I and II as follows:

APPENDIX I

Instructions for Operating Sinking-Pump Switchgear

Before Starting Up

(1) Before starting, inform power house by telephone.

(2) See that the starting transformer is at the "off" position, and that the oil switch and isolating links are open.

Starting Up

(3) Close isolating links. Close oil switch. Put starting transformer quickly in, but not beyond the "starting" position. Watch the ammeter; this will register about 200-250 amperes during starting. When the motor is up to speed, the amperes will fall suddenly to about 60 amps, when (but not before) the starting transformer must be thrown quickly into the "on" position. The gate valve on the pump may now be opened, when the current will increase.

(4) If the motor should not come up to speed in less than a minute, switch off, first the oil switch, and then the isolating links, bringing starting transformer into "off" position, and report immediately by telephone to power house, asking them whether they are ready for another start. If the unsuccessful start is repeated, report immediately to power house, and await instructions.

Shutting Down

(5) Inform power house by telephone. Close gate valve. Open oil switch. Open isolating links. Bring starting transformer into "off" position.

(6) The motor should only be shut down from the pump by means of the emergency switch in case of real emergency, or when changing over, as given in next instruction.

Changing Over

(7) When changing over from one pump to another inform power house. The working pump should be closed down as far as possible without actually shutting it down. The in-going pump is then to be started up in accordance with above instructions. When the in-going pump is up to speed and its gate valve opened, the out-going pump should be shut down by means of the emergency switch. When the out-going pump has stopped, put the emergency switch to the "on" position, thus leaving it ready for starting the pump motor again.

(8) The amperes taken by either of the sinking pump motors, when pumping, must not exceed 82. If this is exceeded the inset attendant must take steps to inform the pump attendant, who must close the gate valve until the current has dropped to 82 amperes.

APPENDIX II

Instructions to Sinking Pump Attendants

General

(1) At the commencement, and at frequent intervals during each shift, the sinking-pump attendant must see that the two motor bearings and the pump-thrust bearing are properly lubricated, and that the bottom bearing under the pump is filled with Stauffer's lubricant.

(2) The packing of the pump gland must be maintained in good condition to prevent air leakages.

(3) The Stauffer lubricators on the pulley pedestals must be screwed up from time to time.

(4) Every precaution must be taken to prevent damage to the cable boxes on the motors.

(5) The pumps must be kept in a clean condition. Dirt and grease must on no account be allowed to accumulate.

(6) The temperature of the jacket of the motor must be observed frequently, and if the motor is found to be unduly warm, the matter must at once be reported.

(7) Any defect in the pumps, motors, cables, or other gear must be immediately reported to the manager or engineer.

Precautions Before Starting Up.

(1) See that the pilot switch is at the "on" position.

Special Note—If the pilot switch is not at the "on" position the pump cannot be started.

(2) See that the gate valve is closed.

(3) See that the strum of the suction is well under water.

(4) Fill the suction pipe and the pump with water from the delivery column, by opening the bypass of the gate valve, and the small valve on the filling piping. When the pump is being filled, the air cocks and the ejector valve must be open, to allow the air to escape from the pump.

(5) After the pump is filled, the air cock and ejector check valve must be closed, and the regulating cock of the cooling water pipe opened. The small valve of the filling piping, and the gate valve bypass, must remain in the same position they occupied when the pump was being filled. When filling the pump, the pressure gauge must be watched, and the bypass valve must only be slightly opened so that the foot valve is not damaged by excessive pressure.

(6) The pump must always be fully charged with water before starting up. If any air remains in the pump, the latter will not work properly, and will have to be shut down.

(7) The shaft coupling must be turned by hand to see that the pump and motor are quite free to rotate.

(8) The sinking-pump attendant must in every instance ascertain from the chargeman that the flexible hose is coupled to the delivery column at the 600-ft. inset before a signal is given to start the pump.

Starting the Pump

(1) The pilot switch must be at the "on" position.

(2) The gate valve must be closed.

(3) The pump must be filled with water.

(4) If one pump is running, its gate valve must be closed for an instant, and must then be opened three complete turns.

(5) Immediately before the signal to start is given, a final examination must be made to see that the in-going pump is full of water.

CODE OF SIGNALS—To start No. 1 pump: Knock 1 and then knock 3. To start No. 2 pump: Knock 2 and then knock 3.

(6) As soon as the in-going pump is up to speed, the oil-circulating system is working, and the cooling water is flowing properly, the gate valve of this pump may be slowly opened to its normal position.

(7) The bypass of the gate valve and the sluice valve of the filling pipe must then be closed.

(8) The gate valve of the out-going pump must then be closed, and the pump stopped by means of the pilot switch.

(9) In the event of the pilot switch failing to stop the pump, the following signals must be given: To stop No. 1 pump: Knock 1 and then knock 6. To stop No. 2 pump: Knock 2 and then knock 6.

(10) After a pump has been stopped, the pilot switch must be placed at the "on" position.

Note—The pilot switch must only be used for stopping the pump when changing over, as stated in the foregoing instructions, or when it is necessary to shut down the pump in case of real emergency.

If the gate valve is opened too wide, a larger quantity of water will be delivered, with the result that the motor will be overloaded.

A Laudable Work

The accompanying photograph of the members of the Coal Miners' Bureau of Research was taken at a banquet recently held at Johnston's Restaurant, Clarksburg, West Virginia.

The Coal Miners' Bureau of Research is an organization of mining men from the vicinity of Clarksburg, and although the membership is largely made up of mine foremen and superintendents, nevertheless there is a goodly representation of miners, inspectors, engineers and operators.

These men meet monthly in the Clarksburg offices of the Consolidation Coal Co. to discuss the many problems that confront them in performing their daily duties. "Safety First" is their slogan. The fact that every man is his brother's keeper has been taken to heart and they are doing what is in their power to safeguard the life, limb and health of their fellow-workmen. The individual views of those present are brought out and discussed. The members are enthusiastic. The organization is growing rapidly. They are doing a good work. May their tribe increase.

COAL-MINING MEN WHO ARE BOOSTING "SAFETY FIRST" IN WEST VIRGINIA

Methods of Weighing and Computing Mine Outputs

By Neill Hutchings*

SYNOPSIS—Inadequate weighing facilities are a prolific cause of labor troubles at many mines. Methods of eliminating these are discussed, and valuable notes are given on the accepted practice in computing production. Because of the varying factors due to washing, boiler consumption, etc., this latter is frequently difficult to arrive at.

There are two main reasons for the weighing of coal: To compensate the miner fairly, and to arrive at the production accurately. The successful operation of a mine necessitates that the amount of coal mined by each miner be determined by weighing. The operator must have the confidence of the miners to the extent of having them feel that every care is taken to pay each one accurately. Nothing on the part of the miner is observed more closely than the weighing of his coal.

The miners will readily contribute a *pro rata* of their earnings to pay the salary of a check weighman, whom they should elect from their own number and whose duty it is to see that all cars are actually and carefully weighed by the company weighman. The employment of a check weighman by the miners should be readily conceded by every coal-mining concern, both as a means of verifying the correctness of the weights and as evidence that the company desires to pay every man all that he earns. Nothing will so quickly establish confidence between the company and the men, while lack of confidence in weights creates much friction and occasionally leads to serious trouble.

Method of Compensating the Miner

The generally accepted plan of arriving at the tonnage of the individual miners is to furnish each man with a number on which to run coal. He is then supplied with brass checks bearing this number, one of which is placed on a hook inside of each car and near the bottom, so it cannot be taken out and another number substituted before it reaches the scales. In the case of cars which are dumped in rotary dumps, the hook must have a clip or spring, so the brass cannot fall out. At the time the car is dumped, the brass check must be removed and handed to the weighman. Right here it should be noted that it is important to have an honest check-puller, and some definite system of handling the checks. In many cases it is easy for a dishonest check-puller to work in collusion with two or three miners and substitute their checks for others when cars are dumped. The superintendent, weighman and check weighman should make it a point to look after the check-pulling carefully.

After the check is handed to the weighman, the weight of the car is recorded on the tally sheet under the number shown, and is then handed to the check weighman to be recorded on his sheet and hung on the check-board. It is suggested that the check-board be constructed so that it will swing in and out of a square opening cut in the weigh shack. The checks are hung on the board inside the weigh house and at the close of each day's work the board is reversed so that the checks hang outside where the men can compare the number of checks on the board with the check weighman's copy of tally sheet posted thereon, without having to crowd inside. This arrangement also enables the men to get their checks as early as they like in the morning, as in many cases men go to work before the weighmen arrive.

Pick and Machine Mining and Dockage

The company weighman and check weighman should make it a rule to balance their sheets at the close of each day's work and the number of checks hung on each numbered hook should agree with the number of cars credited each man on the tally sheet.

Brass checks are best in tallying coal, as leather checks, etc., are difficult to read after becoming soiled. The cost of brass checks is so small and their use so desirable for accurate reading and recording that most companies will find it a paying proposition to furnish them free to the miners and insist that no other kind will be recognized.

Both the company and check weighman should arrive at the mine early enough to see the men before they go in, as many questions arise, even under the best conditions, which the weighmen must be right on the job to take care of. This will save many a trip to the superintendent on the part of the men to secure adjustment and settlement of questions as to tonnage credited, etc. This results in real money saving to both the men and the company.

A distinction should be drawn between pick and machine numbers in mines where there are both, so that the tally sheets will show the amount of each in order that the rate may be properly applied. The best plan of doing this is to have the mine foreman or machine foreman, make up an additional daily report, showing the name and number of each man loading machine coal This should be sent to the time office daily and checked with the tally sheet to see that the machine numbers agree.

In handling dockage the general plan should be to allow the miner credit for his full tonnage, and after the dockage report is looked over and passed on by the superintendent, to charge the miner with the amount. This plan is better than deducting the daily dockage from the daily tonnage because in many cases allowances are made on account of wet places, etc., which would necessitate refunds.

Arriving at Production

In selecting weighmen, care should be taken that only men who are honest and possess the faculty of treating men fairly and courteously be employed. Lack of tact and diplomacy on the part of weighmen, timekeepers and such employees is often responsible for the loss of good miners. The best place to head off trouble is at its source.

The production of a mine should not be considered as

*Accounting Department, T. C. I. & R.R. Co., Brown-Marx Bldg., Birmingham, Ala.

the total of the tipple weights, but is in fact the total tonnage of coal shipped, coked, used for plant purposes, etc. Shipments to market will usually be the largest item. The greater part of the coal will then be weighed in railroad cars over track scales. Where the product used for coking purposes is washed, this should be weighed before going to the ovens. It is desirable to compile monthly figures of the production of a mine in such a way that the total tipple weights will be exhibited in one place and the total inventory or production figures in another. This will show clearly any difference existing as the result of practice and methods pursued. These exhibits should be made up about as follows:

TIPPLE WEIGHTS		
Machine coal paid for	Tons	(pay-roll figures)
Pick coal paid for	Tons	
Dockage	Tons	
Company coal	Tons	
Total tipple weights	Tons	
INVENTORY WEIGHTS		
Shipments to market	Tons	(billing figures)
Dry coal to ovens	Tons	
Dry coal to washer	Tons	
Dry coal to boilers	Tons	
Coal sold employees	Tons	
Slate from picking tables	Tons	
On hand	Tons	
Total inventory weights	Tons	

The item "On Hand" should exhibit the difference between the coal on hand in bins, railroad cars, etc., the first and last of each month. An increase over the previous month can be shown in black and decrease in red.

The tipple weights practically represent the coal paid for, so every concern will carefully scrutinize the total of tipple and inventory weights and endeavor to reconcile or find the cause of any existing differences. When tipple weights exceed inventory weights, the company will be paying for more coal than it is apparently getting. When inventory weights exceed tipple weights, the company is apparently not paying the men for all the coal produced.

The adjustment of differences in tipple and inventory weights must lie in a careful study of existing practices in handling and disposing of the product. At this point many factors arise affecting the final or inventory production of a mine. The product at some mines can be readily marketed without any treatment whatever. If the railroad cars are weighed correctly on track scales, these weights should agree very closely with the tipple weights. Thus the production of the mine is easily ascertained and any small differences can be easily reconciled.

Difficulties in Determining Production

This desirable condition exists at but few mines. At most plants conditions have arisen in the manufacture of coke and the use of coal which necessitate the removal of certain natural elements and impurities by process of crushing, washing, etc. From coal considered as average grade, from 1 to 2 per cent. will sometimes be taken out in this manner. The dockage for this will, in few cases, amount to anything like 1 or 2 per cent. In a great many cases where coal washers are installed, the modern practice is to locate same in close proximity to the mine tipple in order to secure economic delivery from the tipple screens to the washer. In most cases slack is conveyed directly to the washer without weighing. In the process of washing, the slate is eliminated and the wet coal from the washer is either loaded in railroad cars or larries and after being weighed over track scales, is delivered to the ovens or shipped to market.

In figuring the production the tonnage of dry coal delivered to the washer must be known. If it is not weighed before delivery, this can only be figured by a backward process, and in doing this several matters of importance must be considered. One is the amount of slate or refuse taken out of the coal in washing. Unless this can be weighed accurately, the best method of determining the amount is to load the refuse evenly in cars. A careful count of those must be kept and this can be multiplied by the cubical contents of the car in dry refuse to ascertain the total amount. This can be verified from time to time by independent tests. Another factor is that of moisture in washed coal. This must be determined by daily sampling and analysis.

In order to ascertain the amount of dry coal delivered from tipple screens to the washer, it is necessary to take the weight of washed coal loaded in railroad cars or larries, deduct the moisture and add the refuse. In cases where coal is delivered to the washer without being weighed, this is a very important factor in arriving at the production of a mine. It is easily seen that if the moisture or refuse figures are not right, the wrong amount of dry coal delivered to the washer will be obtained. Sometimes it will happen that enough fine coal is carried off in the discharge water from the washer to amount to several hundred tons a year. This is a feature not always considered in the monthly analysis of tipple and inventory weights.

Another vital factor in arriving at the production is the coal consumed at the boilers. In a great many cases coal is delivered to the boilers in mine cars and the tipple scale weights can be used. However, it is a common thing to find coal being delivered by means of conveyors, and in such cases it is rarely weighed and is difficult to estimate. There are good reasons in plenty why coal used for steam purposes should be weighed independent of the value of correct weights for figuring production. The knowledge of the weight of coal consumed is an important factor in working up the cost of steam and the boiler-horsepower-hours.

Factors Affecting Production

It should be clear that the task of arriving at the final production figures for a coal mine embrace the consideration of several important factors and it is obvious that in practice every difference as between tipple and inventory weights cannot be explained clearly on account of the varying factors. Here are some points to be observed closely if the accuracy of production figures is desired:

Inspect and test tipple scales frequently.

Weigh sufficient empty mine cars once a month in the presence of a committee of miners to establish an average tare weight for mine cars.

Weigh all coal delivered boilers.

Weigh refuse from washers. (If possible, refuse should be loaded in railroad cars so track scale weights can be secured.)

Make frequent tests to determine the percentage of moisture in washed coal.

In conclusion, attention is called to a feature of great importance—that of the careful and commonsense weighing of coal over tipple scales. A mine tipple should be so arranged that the cars will slowly drift over the scales without being pushed. It is a common thing to see two or three tipplemen pushing cars over the scales. This naturally adds something to the weight of the car and if allowed for a considerable period the company will pay for something it does not get.

West Virginia Operators Appoint Safety Inspectors

SYNOPSIS—The recent action of certain West Virginia operators appointing safety inspectors for their mines, typifies the general growth of the "Safety-First" idea. A résumé of the duties of a safety inspector.

The "Safety-First" idea has been "taking hold" of late in a most gratifying manner. Popular sentiment finally has become aroused, and much is being said and written on the subject. But even more auspicious than this, is the fact that legislation, directed at the more adequate protection of life, is being both enacted and enforced.

A notable example of this latter was the sustaining, by the U. S. Supreme Court, of the Pennsylvania "Mine-Safety" law, requiring coal operators to leave standing pillars of coal to prevent cave-ins; in the test case of the Plymouth Coal Co. vs. David L. Davis, state mine inspector of Pennsylvania.

There are laws of a like intent in many other states; which is as it should be—for it is not only desirable, but necessary, that we have adequate legislation for the conservation of life and the protection of property.

Of even greater importance, from a practical standpoint, is the tendency of certain representative coal operators to "go on their own" in this respect. Initiative in the right direction is always commendable, and, in this connection, it is something more than that—it is conspicuous. In the past, the promulgation of the "Safety-First" idea has been too often left to lay editors, college professors and stump orators of a political ilk. Yet, even so, the seed was sown which was destined to achieve fruition in the brain of the operator.

A noteworthy example of this is seen in the recent action of certain operators in the West Virginia field, who voluntarily have appointed "safety inspectors" for their mines, in an effort to reduce accidents and fatalities, a splendid example for emulation. Moreover, these operators were not content in carrying out merely their personal obligations in this respect, they went further; they prepared a general letter, over their several signatures, which they forwarded to Earl A. Henry, Chief of the Department of Mines of West Virginia, wherein they outlined the duties of a "safety inspector," as they conceived them, and urged that he use his influence in securing similar action from all other operators in the state.

On receipt of this appeal, Mr. Henry mailed a copy of the letter to every coal operator in West Virginia, urging each to adopt similar provisions for the protection of the lives of those with whose safety they are charged.

Wherefore, let us accord all honor to these progressive and fair-minded operators, and to Chief Inspector Henry.

The letter, which deserves the careful consideration of all concerned, is reproduced below:

Dear Sir—This is to notify you that we have this day appointed a man to fill the position of safety inspector for our mines.

The object of this office is to add to the safety of our employees and the sole duties are to assist the mine foreman in regard to safety to employees.

The entire time must be spent in making inspections of the working places, haulways and traveling ways; he must see that the law is complied with in every respect and that the rules and regulations governing the operation of these mines are closely observed and adhered to, and he shall give all workmen instructions as to safety and safety-methods that are established and may be established in the future.

The following is a list of his duties in detail:

First: He must see that all persons going to and from work enter cars while stopped, that they sit down inside of cars and not up on the side, or on the bumpers, and that all persons remain inside of cars until they come to a dead stop. in no case must he allow persons to get on and off cars while in motion. See that the motormen engaged in hauling men trips use the proper care both as to speed and rough handling.

Second: See that no person carries any larger amount of powder or other explosives into the mine than the law permits.

Third: He shall visit all working places, at least every alternate day, and as much oftener as possible, see that they are in a safe working condition. that all loose coal, slate and rock is taken down, or securely propped, and that the coal is being blasted in accordance with law and rules governing the mine, and that a sufficient amount of air is in circulation, that break-throughs are properly driven, that the oil regulation is not violated, and that men do not carelessly handle powder or other explosives, and that props and caps and all necessary timber be kept up by the workmen and in no case allow them to take any risk for the want of timber; if the timber cannot be had, they must suspend work until same can be furnished. In the event he finds a person working under loose coal, slate or rock, he shall stay with him until same is made safe. Start a system of setting timbers in rooms, the maximum distance apart shall be 3½ ft. and as much closer as the nature of the roof may require; a standard distance of 12 in. from the rail is required, and all posts must be set in the best position to support the roof, which position is most generally at right angles to the weight or roof.

Fourth: He shall examine the roof along the haulways and traveling ways and mark all loose slate to be taken down, and when, in his judgment, he deems it unsafe to wait until after working hours to have it removed, he must have it removed at once, regardless of cost. In no case must he permit any person to work in an unsafe place, except for the purpose of making it safe, and in case it is extra hazardous he shall remain with the workmen until same is made safe.

Fifth: He shall make a daily report of his inspections in a book which is to be kept in the office of the mine superintendent for his examination. He shall be subordinate to the superintendent and keep him informed of any violations of the rules and of his inability to comply with the law or rules, by lack of material of any kind. His daily reports shall consist of the condition of the various working places he visits, violation of the rules and law, by whom, when, where and how, steps taken to remedy same. If any person or persons shall try to intimidate him in the discharge of his duties, state same in his daily report, give name and nature of the offense, and said person shall be dealt with severely.

Sixth: It shall be his duty to see that all stretchers, blankets, etc., are kept in readiness, and that same are returned to their places after being used. He shall include this in his report. A medicine chest with bandages, plaster, cotton, tourniquet, splints and other appliances to render first aid will be in the mine superintendent's office for use in case of emergency. He will be given a key to said office.

Kentucky Mining Institute Meeting

The annual meeting of the Kentucky Mining Institute will be held in Lexington, Ky., again this year on May 8 and 9. A special feature of the meeting will be the state-wide first-aid contest, in which a number of first-aid teams from the various mining companies will participate.

As an attraction for the first day's meeting, it is hoped that the Federal Bureau of Mines will place its immense explosion gallery in Lexington for a demonstration of the explosibility of coal dust, and the dangers of blasting coal with black powder in the presence of dry coal dust.

It is proposed to have a mining show during the meeting, and Secretary Cramer has asked a number of manufacturers to send exhibits for this purpose.

Great Britain is estimated to have a reserve of 189,534,000,000 metric tons of coal, most of it bituminous, while France has 17,584,000,000, also chiefly bituminous. Germany's actual reserve is 94,865,000,000 tons of bituminous and 9,314,000,000 of brown coal, though it is probable that there is a large further reserve.

Agreement to End Strike

SYNOPSIS—A satisfactory and equitable agreement drawn by the company officials in consultation with a duly authorized committee of their employees, which agreement is to remain in force for two years and seven months and has been ratified by vote of the men.

We give below the full text of the agreement entered into early last month between the Western Fuel Co., Nanaimo, B. C., Can., and its employees. The agreement is for a term of three years and its provisions are said to be eminently satisfactory to all parties concerned, and such as will tend to guarantee peace and harmony in the Island of Vancouver, it is hoped, for years to come.

Although the agreement concerns only the underground men, the Western Fuel Co., in keeping with their general practice of looking after the welfare of all their employees, are revising the wage scale of the men employed on the surface, such revision to take effect from the date of the agreement with the underground employees.

In addition to the general agreement, which formed the basis of the settlement of the strike conditions, an insurance scheme has been adopted as a result of the unanimous vote of the men ratifying the agreement, at one of their mass meetings. The insurance plan is appended as a supplementary agreement to the main contract. The full text of this insurance plan and agreement is given below:

Memorandum of Agreement entered into this sixth day of March, 1914, between the Western Fuel Co., hereinafter called "The Company," party of the first part and the employees of the Western Fuel Co., represented by an Agreement Committee, elected at a duly called mass meeting, held Feb. 18, 1914, party of the second part:

Witnesseth—That, for and in consideration of the several conditions hereinafter mentioned and the mutual advantages of both parties, it is agreed by and between the parties hereto, as follows:

1. The rates, terms and conditions in effect at both No. 1 and Northfield Mines, during the month of April, 1913, shall continue in effect during the term of this agreement, except as hereinafter provided.

2. The company agrees to pay all employees covered by this agreement a bonus of 10 per cent. during the term of this agreement; being an addition of ten (10) per cent. to all rates and wages herein specified.

3. The company shall absorb the expense of operating the Protection Ferry.

4. The system of dockage inspection, as practiced at both No. 1 and Northfield Mines shall be continued, with penalties for refuse matter as follows:

No. 1 Mine—Up to and including 50 lb. of refuse per car, double dockage. Over 50 lb. and including 100 lb. of refuse per car, confiscation of car. Over 100 lb. of refuse per car, dismissal after investigation.

Northfield Mine—Up to and including 70 lb. of refuse per car, double dockage. Over 70 lb. and including 140 lb. of refuse per car, confiscation of car. Over 140 lb. of refuse per car, dismissal after investigation.

Provided that any party dismissed may have the right of appeal to the superintendent of mines, whose decision shall be final.

5. The company agrees to a minimum rate of three dollars and fifteen cents ($3.15) per shift, for miners in the lower-seam workings of No. 1 and Northfield Mines. It is understood that the superintendent of mines shall be the judge as to the ability of the party to earn such minimum rate.

6. The company agrees that when a miner is taken from the face to perform daywork he shall receive the miner's day rate.

7. The schedule for loading coal shall be as follows: Upper seam, 30c. per ton; lower seam, 35c. per ton; and for using buggies and laying roads at:

No. 1 Mine—First 75 ft. from dump to face line, five (5) cents per ton additional.

Second 75 ft. from dump to face line, ten (10) cents per ton additional.

Northfield Mine—First 50 ft. from dump to face line, five (5) cents per ton additional.

Second 50 ft. from dump to face line, ten (10) cents per ton additional.

Third 50 ft. from dump to face line, fifteen (15) cents per ton additional.

8. The schedule for rock in coal of upper seam shall be as follows: When rock is 1 ft. thick, $1 per yd. When rock is 2 ft. thick, $2.40 per yd. When rock is 3 ft. thick, $4 per yd.

Above schedule applies only to solid work in stalls. Skipping pillars take one-half of these rates.

9. The schedule for timbers to be as follows: Stringers, 50c. each when 8 ft. long and under; $1 each when over 8 ft. long. Sets, $1.50 each for 9-ft. collars; $2 each for 11-ft. 4-in. collars.

10. The mining, yardage and day rates for No. 1 Mine shall be as shown on Schedule "A," hereto attached and which schedule is made part of this agreement.

11. The mining, yardage and day rates for Northfield Mine shall be as shown on Schedule "B," hereto attached, and which schedule is made part of this agreement.

12. The agreement committee shall consist of three members representing No. 1 Mine, two members representing Northfield Mine and two members representing any new mine operated by the company, after the new mine has been placed on an operating basis.

The company agrees to meet the agreement committee, or a subcommittee thereof, on matters relating to this agreement or any new matters changing the status thereof, or to adjust any matters in dispute between the employees and mine officials; it being distinctly understood that there shall not be any stoppage of work by employees, individually or collectively, pending the hearing of and adjustment of any dispute or grievance during the term of this agreement.

Any vacancy on the agreement committee is to be filled at a duly called mass meeting of the underground employees of the company, or by a pit-head ballot at the mine from which the vacancy exists.

The agreement committee to have the handling of the checkweighmen and gas committee funds.

13. The term and duration of this agreement shall be for a period of two years and seven months, beginning Mar. 1, 1914, and terminating Sept. 30, 1916; and during the month of August, 1916, a mass meeting of the underground employees shall be held to elect a new agreement committee to negotiate a new working agreement, said meeting to be called by the chairman and secretary of the existing agreement committee.

14. This agreement shall be binding upon and respected by the company and its successors, and also shall be binding upon and respected by all employees, who before accepting employment shall endorse this agreement, by their signature in a book containing a copy of this agreement and kept in the company's office: PROVIDED that all employees working for the company at the time of the execution of this agreement and who continue to work for the company shall, by such action, be understood as agreeing to and endorsing all the terms and conditions of this agreement.

15. The day rates applying to No. 1 Mine, and the contract rates applying to the south side of No. 1 Mine, shall apply to and govern all classes of underground work at the new Reserve Mine, when that mine is placed upon an operating basis, and shall continue as the rates for that mine during the term of this agreement unless changed by mutual agreement.

The Reserve Mine when placed upon an operating basis shall have a representation of two members upon the agreement committee, who shall be elected by a pit-head ballot at the mine.

16. This agreement to be effective shall bear the signatures of the manager and superintendent of mines for the company, and the agreement committee for the employees, and the approval signature of the president of the company.

SIGNED, SEALED AND DELIVERED, the day and year first above mentioned.

SCHEDULE "A"

Mining, Yardage and Day Rates—No. 1 Mine

Mining—Upper seam, per ton, 68c.; lower seam, per ton, 80c.

Yardage, Upper Seam—Levels, $2.50 per yd. and coal. Crosscuts, $2 per yd. and coal. Levels, when less than one-half of height is in white rock, $7.50 per yd., coal to company. Levels when more than one-half of height is in white rock $8 per yd., coal to company. Turning stalls, 5 yd. long by 12 ft. wide, $10 and coal.

Day Rates—Fireboss, $3.65; shotlighter, $3.40; face men, $3.20; bratticemen, $2.85 to $3.15; timbermen, $3.15; timbermen helpers, $2.75; tracklayers, $2.85 to $3.15; tracklayers' helpers, $2.75; roadmen, $2.75; drivers, boss, $3.25; drivers, double, $3; drivers, single, $2.87½; drivers, boys, $1.60 to $2.40; pushers, $2.75; linemen, $3.10; motormen, $2.87½; motormen assistants, $1.60 to $2.40; engineers, diagonal slope, $2.85 to $3.15; engineers, endless rope, $2.75; winch drivers, $1.10 to $2.75; rope inspector, $3.15; endless ropes, men, $2.75 to $2.90; endless ropes, boys, $1.35 to $1.90; rope riders, $1.60 to $2.75; doorboys, $1.10; cager, head, $3.15; cager, assistants, $2.75; miners, $3.15; loaders, $2.75; machine foremen, $3.70; machine runners, 1st class, $3.65; machine runners, 2d class, $3.25; machine runners, 3rd class, $3; machine runners, helpers, $2.75; drillers, 1st class, $3.65; drillers, 2d class, $3.25; drillers, 3rd class, $3; muckers, $2.75; brushers, $2.80; cogmen, $2.75; laborers, $2.75; pipemen, $2.75 to $3.10; pumpmen, $2.75 to $2.85; stablemen, $2.85.

SCHEDULE "B"

Mining, Yardage, and Day Rates—Northfield Mine

Mining—Upper seam, per ton, 68c.; lower seam, per ton, 80c.

Yardage, Upper Seam—Levels, $2.50 per yard and coal. Crosscuts, $2 per yd. and coal. Levels, when less than one-half of height is in white rock, $7.50 per yd., coal to company. Levels, when more than one-half of height is in white rock, $8 per yd., coal to company. Turning stalls, 5 yd. long by 12 ft. wide, $10 and coal.

Day Rates—Fireboss, $3.65; shotlighter, $3.40; facemen, $3.20; bratticemen, $2.85; timbermen, $3.15; timbermen helpers, $2.75; tracklayers, $2.85 to $3.15; tracklayers helpers, $2.75; drivers, boss, $3.25; drivers, double, $3; drivers, single, $2.87½; drivers, boys, $1.60 to $2.40; pushers, $2.75; rope inspector, $3.15; endless ropes, $2.40 to $2.90; rope riders, $1.60 to $2.75; winch drivers, $1.10 to $1.60; doorboys, $1.10; cager, $2.90; miners, $3.15; loaders, $2.75; machine foremen, $3.65; machine runners, 1st class, $3.65; machine runners, 2d class, $3.25; machine runners, 3d class, $3; machine runners, helpers, $2.75; drillers, 1st class, $3.65; drillers, 2nd class, $3.25; drillers, 3rd class, $3; muckers, $2.75; brushers, $2.80; cogmen, $2.75; laborers, $2.75; pipemen, $2.75 to $3.15; pumpmen, $2.75; roadmen, $2.75.

Supplement to Agreement dated the sixth day of March, 1914, between the Western Fuel Co. and its employees represented by the agreement committee:

A It is agreed that in the event of a fatal accident occurring in the mines, or in event of a death resulting from injuries received in the mines, that the operation of the mine in which the accident occurred shall not be suspended on the day of the funeral of the deceased party, but that any employee wishing to absent himself from work for the purpose of attending the funeral shall have the privilege of doing so.

All employees working on the morning, afternoon and night shifts of the day of the funeral agree to contribute the sum of one dollar ($1) per man and fifty cents (50c.) per boy, to a fund to be given to the nearest relative of the deceased party.

The company agrees to duplicate the sum contributed by the employees.

For the purposes of this section all employees whose daily wage is less than three dollars ($3) per shift shall be considered as boys.

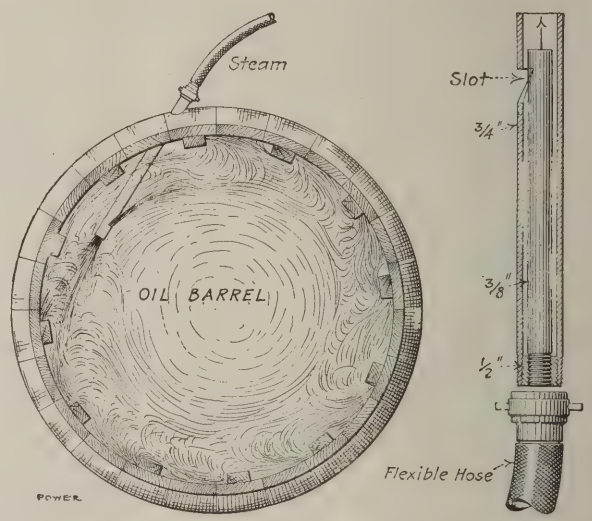
The company is authorized to make collections for this fund from the payroll of its employees in manner similar to other collections.

Nothing in this section shall relieve the company of any obligation under the Workmen's Compensation Act, nor shall it relieve the employees of their obligation to the Medical Relief and Accident Fund.

B It is agreed that monthly meetings of the management of the company and the agreement committee shall be held on the first Wednesday of each month at two o'clock in the afternoon at the company's general office.

Special meetings may be called at any time by the management of the company or the chairman of the committee, due notice of such meeting to be given to all parties.

SIGNED, SEALED AND DELIVERED, the sixth day of March, 1914.



FOR THE COMPANY—
THOS. R. STOCKETT, Manager.
JOHN HUNT, Superintendent.

FOR THE EMPLOYEES—
JOSHUA NORRIS,
JAMES H. ROBERTSON,
ANDREW THOMSON,
JOSEPH DEAN, Secretary.
JAMES MILLER, Chairman.

Steam Washer for Cleaning Overalls

The accompanying sketches show an arrangement a fireman made for washing overalls after considerable experimenting with several similar ideas, none of which was so satisfactory as this.

The outfit as shown consists of a barrel with an injector-like apparatus which may be connected to a steam

PLAN OF WASHER AND SECTION OF NOZZLE

main through a flexible hose connection. Around the sides of the barrel is a series of vertical slats to break up the steady rotation of the water which the injector action gives and to set up counter-current, so that the clothes to be washed are thoroughly agitated.

The barrel is an ordinary oil barrel; the injector was built up of three standard sizes of pipe assembled as shown in the sketch—*Power*.

Canadian Coal Production

The estimate of John McLeish, chief of the Division of Mineral Resources and Statistics, for Canada, shows the production of coal in the Dominion in 1913, and the revised figures for 1912, to be as follows:

	1913	1912
Nova Scotia	7,972,727	7,783,888
British Columbia	2,714,449	3,208,997
Alberta	4,144,377	3,240,577
Saskatchewan	209,175	225,342
New Brunswick	70,311	44,780
Yukon Territory	4,050	9,245
Total for Canada	15,115,089	14,512,829

The output in 1913 was unfavorably affected by labor troubles in Vancouver Island, British Columbia.

Editorials

One Way to Advance Loyalty and Efficiency

The greatest problem of industrial life today is the task of effecting a proper relationship between employer and employee. If satisfactory results are to be obtained in the way of loyalty and efficiency, the workman must be encouraged to have confidence in his superiors.

In furtherance of this end, it is an excellent suggestion that the president, or whoever is the supreme official of each corporation, invite every man in his employ to communicate directly with him, by personal interview or letter, whenever real occasion arises. Nothing is better calculated to foster this feeling of confidence on the part of an employee than the certain knowledge that his ideas, suggestions and complaints will receive the personal attention of the man-at-the-top without first going through the hands of subordinates. Most workingmen have confidence in the "big boss." On the other hand, they are sure to have a feeling of distrust for the small understudy. And this condition is not without cause, for it often occurs that petty officials endeavor to advance themselves in the eyes of their superiors by presenting suggestions from the men under them as their own original ideas.

It will be claimed by some that a plan built on the lines here suggested would be destructive of discipline. This is not true, as has been proved by the successful adoption of such a system at several of the largest industrial plants in America. Great good is sure to result when the workingman is brought to feel that the highest official of his corporation is taking a personal interest in him and is ready to discuss proposals for company betterment with him man-to-man.

The Western Fuel Co. Agreement

The Western Fuel Co., Nanaimo, B. C., Can., and Thomas R. Stockett, the genial and efficient manager of the company, are to be congratulated on the agreement entered into between the company and its employees. This agreement is the culmination of the strike difficulties that have existed in Vancouver Island during the past 18 months.

The trouble arose from the attempt of the United Mine Workers of America to extend their organization and influence into British Columbia. Agitators were sent into the Island of Vancouver to arouse the interest of the miners in the Island and enroll them as members of the organization. These efforts met with indifferent success, owing primarily to the fact that the Vancouver miners were working under conditions with which they were generally satisfied.

According to the evidence that developed on the investigation of mining conditions in the Island, by the government, a general walkout that was in effect equivalent to a strike, was brought about by the strategy of inducing the miners to vote a "holiday," after which coercive measures were used to prevent the return to the mines of those men who were willing and desired to work.

In this case, as in a number of other similar instances, elsewhere, the broad principle was overlooked by the strike makers that, *Every man has a right to work without interference or intimidation by other workers of a different mind.* No argument is needed to emphasize or explain this *right of the individual.* It is the foundation principle of all industry. Any curtailment of the *right to labor* is contrary to the law of self-support and good government, and its advocacy by any individual or organization is evidence in itself of *lawlessness.*

The manner in which mining operations have been conducted in the Island during this period of disturbance is greatly to the credit of the management of the coal companies, not a little credit being also due the large majority of the men, for their loyalty to their employers. It can be truthfully said that few companies have done more than the Western Fuel Co. to improve the conditions in and around their mines, and to encourage the spirit of coöperation among the workers. These efforts on the part of the company have been fully appreciated by the majority of their employees, who resisted, to the extent of their power, the unjust interference of the few with the operation of the mines.

We give in another place the full text of the agreement of Mar. 6, 1914, which is to extend over a period of three years.

Coal Buying on a Large Scale

In the recent request for bids involving 640,000,000 lb. of coal per annum to supply the state of New York with fuel, a new and commendable precedent in coal purchasing has been established. Obviously, a deal of this magnitude will enable the bidder to compute his profit at the lowest conceivable margin, much to the benefit of the purchaser.

While this is, of course the predominating reason for this new departure, it will probably develop eventually that the scheme has other and even more important advantages. For instance, under the present system of coal buying, each institution acts on its own initiative without expert advice of any kind. In many instances, the medical officers at the state institutions are called upon to decide their own fuel problems, while in general the question is seldom or never handled by really competent men.

Under the new arrangement, the state will derive the benefit naturally to be expected from the best services available. A special commission, made up entirely of fuel experts, will study the different problems in all their ramifications and select the fuel best adapted to the requirements of the individual plants. It may even eventually develop that the economy in consumption this commission is able to effect will be of even greater importance than the amount saved in buying.

That the buying is to be done entirely on the B.t.u. basis will be construed as an important recommendation of this system by its advocates. However, it is possible that a deal of this character, offering such opportunities for favoritism, could only be handled in this manner. The specifications drawn up by the commission are essentially practical and contain but few points with which the responsible bidder could take issue. From a cursory examination of them, the most objectionable feature seems to lie in the proposed schedule of payments which provide for much longer delays than is prescribed by the rules of good business or that the operators in general would ordinarily consider. But since the obligations of a commonwealth such as New York are readily negotiable at a minimum discount, this feature is insignificant.

Stone-Dust Stoppings

In an inquiry published in the last issue of COAL AGE, March 28, p. 539, the question was raised as to the feasibility of building what might be called "stone-dust stoppings," consisting of two walls of slate or rock, with the intervening space filled with fine stone dust. The argument advanced in favor of this suggestion was that, in case of an explosion, and the destruction of the stopping by the force of the blast, the stone dust would be thrown into suspension in the air, at the moment and at the place most needed to arrest the explosive wave.

We believe that this suggestion is worthy of consideration. The efficacy of stone dust to stop the progress of an explosion in underground passageways has not as yet been thoroughly tested. Many experiments seem to indicate that this is an effective method of destroying the explosive condition of mine air. We believe that more attention should be given to the matter of applying this principle in coal mining.

At the present time, it is common practice, in many mining districts, to build road stoppings by erecting a double wall of slate and filling the intervening space with road dust. This dust, however, is largely contaminated with fine coal dust and is to that extent combustible and dangerous to be used for the filling of stoppings. The question to be decided is: Is stone dust sufficiently efficacious in arresting the explosive wave to warrant the expense of crushing and pulverizing slate and rock for this purpose? We would be glad to see this question thoroughly discussed by those who have had experience in the use of stone dust for this purpose.

Some Things Are Beyond Understanding

"Safety First" received a hard jolt recently when the miners employed at mines No. 19 and 20, of the J. R. Crowe Coal Co., near Pittsburgh, Kan., walked out and refused to work because R. A. Gray, general superintendent for the coal company, posted safety-first signs in and about the mines. They were placed on the tipple, in the engine and boiler rooms, at the pit-head, at the powder house and at different places in the mines, where there was the least bit of danger to be encountered. The pit cars were adorned with the signs, and the mottoes were conspicuous in the weighing office and on the screens—in fact, they were placed in every prominent position available in and about the mines.

Shortly after the signs had been posted, the mine committee for the United Mine Workers waited upon Superintendent Gray and asked that he remove the warnings. In his surprise, he refused their demand, and at once a strike was ordered and immediately put into effect at both mines The men gave no reason why the objection was raised further than to say they are able to take care of themselves without having danger signs facing them at every turn. Over 400 miners are engaged in the strike and the grievance has been referred to the executive board to be settled.

If anything could be done to dampen the ardor and smother all enthusiasm on the part of a mining company for "safety" in their operations, surely the Kansas miners have selected that course. Let us all hope that the miners of the Crowe company are in a class by themselves. We also trust that justice and retribution be delayed in their case until they have been brought to see the great harm they are working against the cause of organized labor in the mines of America.

Operators Are Not a Unit

The differential for machines is less in Illinois and Indiana than in Ohio, and this fact has made a difference in interest between the operators in those states. The Ohio operators may be expected to resist the Green Anti-Screen Bill to the bitter end, but the result is hardly likely to be more successful than the attack in Illinois on the practice of solid shooting.

The greatest difficulty operators in Illinois have to contend with is the multiplicity of separate scales existing in that state. This condition makes the Illinois owners anything but a unit.

There has been some talk that the Illinoisans were going to draft an equal scale from end to end of the state. We know for a fact that such action will not be sanctioned by some of the large operators in Illinois.

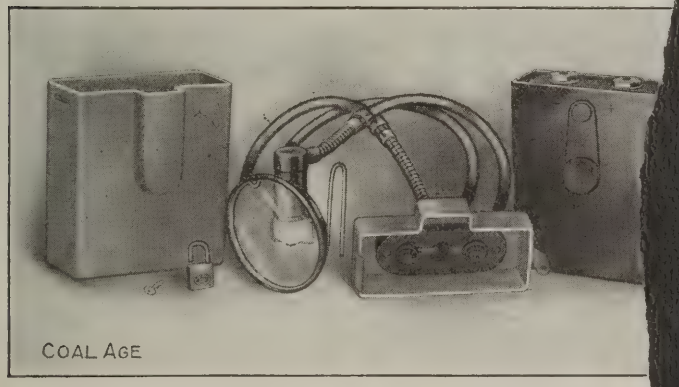
Wanted--a Leader

Probably never before in the history of the bituminous-coal industry was there such urgent need of a generalissimo of the army of operators. Grown complacent under the soothing belief that the miners cannot precipitate an industrial strife, because of depressed business conditions, the lack of cohesion, and uniformity of action in a national wage agreement was never before so evident.

Independence of initiative is the salient feature in all sections, and the miners are showing themselves quick to accept the possibilities of this chaotic situation by completing the disruption of what meagre semblance of organization still prevails between the contiguous states. Acting upon their own motto, "United we stand, divided we fall," the miners will first effect a dissolution of the producers' organization into its constituent elements and then by concentrating all the powerful resources of the U. M. W. of A. upon each unit in turn, a victory will be ultimately assured.

The Pittsburgh district has its John H. Jones and W. K. Field, Ohio, its Woodford, its Maurer and others, while Illinois boasts its Peabody, Scholz, Taylor, Moderwell and Moorshead, but where is the man who can weld these units into a whole?

The Situation at the Labor Conferences



The overtures of the miners of the Pittsburgh district asking for a continuation of the previous scale were accepted at Pittsburgh, Mar. 30. Essentially this same plan was offered at the Chicago conference, but could not be accepted by any single state at that time. Immediately upon the adjournment of the Convention, the policy committee of the miners decided to offer it individually to the separate districts with the result that an agreement was effected on this basis in the Pittsburgh district.

Because of the complications arising as a result of the new mine-run law in Ohio, it will be impossible to arrange a new scale on the same basis as the one just expired. There are also serious difficulties in the way of an agreement being reached in Illinois, but indications point to an early settlement of the Indiana scale.

While no formal suspension of mining will take place in the Pittsburgh district, operations will necessarily be restricted, pending the liquidation of heavy stocks accumulated in anticipation of the more or less protracted suspension. The output of this district since the cessation of lake shipping last fall has averaged 70 per cent. of full rated capacity, whereas consumption during the past two or three months has probably not exceeded 50 per cent. normal. Thus in order to permit consumption to catch up with production, operations will probably be at about 50 per cent. until lake shipping opens up.

A Locked-Case Electric Safety Lamp for Use in Gaseous Mines

After securing the approval of the U. S. Bureau of Mines for the use of its lamps in gaseous mines, the Witherbee Igniter Co., manufacturer of the Wico lamp, proceeded at once on the attainment of its ultimate ambition, to produce an indestructible lamp.

SHOWING IMPROVED WICO ELECTRI

In the meantime, a demand had sprung up for a locked case construction which would prevent the connection being tampered with from the time the equipment left the lamp house until its return. Hence the Wico locked case electric safety lamp was made to combine this feature with the necessary protection for the battery. It may now be dropped from a height of 5 ft. on solid rock without danger of breaking the battery jar, and, in testing, the lamps have been dropped from a height of 20 ft. on frozen ground without injury.

It has been determined in practice that a charge of 5c. per day to the miners for the use of the lamp will not only keep the batteries charged, but purchase a new equipment at the end of the year. Most of the parts of the locked-case type will last many years.

The accompanying illustrations show how the hinge and hasp for the padlock are case-integral with the case and cover. The safety device which extinguishes the glowing filament in case of bulb breakage, makes the replacement of the standard Ediswan bulb easier than the bayonet-lock formerly used. Complete dissembling of the equipment can be accomplished in a few minutes. All parts are made interchangeable in accordance with the best American practice. The aluminum case is a remarkable example of metal casting. Battery efficiency has now been fully demonstrated in practice, both as to hours of service on a charge and retention of liquid electrolyte.

The locked-case Wico lamp may be seen in use at the government's experimental mine at Bruceton, Penn.

England Faces a Big Coal Strike

Supported by the Miners' Federation of Great Britain, 135,000 coal miners in the Yorkshire pits, in Yorkshire, have gone on strike, demanding the introduction of a minimum rate of wages; 150,000 more miners have declared their intention of striking this week if their demands are not granted immediately. The situation is serious and it is expected that there will be a long str[illegible] before an adjustment is effected.

Legal Department

Recent Judicial Decisions

By A. L. H. STREET*

North Dakota Coal Freight Rates—The North Dakota law of 1907, which prescribes maximum freight rates on interstate shipments of lignite coal, is found to be reasonable as to some of the railroads in the state and unreasonable as to others. (North Dakota Supreme Court, State vs. Northern Pacific Railway Co., 145 Northwestern Reporter, 135.)

Assignment of Mining Leases—A clause in a coal mining lease prohibiting assignment of the lessee's interest without the lessor's consent is waived by his acceptance of rent from the assignee. The lessee, however, remains liable on his express agreement to pay rent for the full time the lease shall run, unless the lessor accepts the assignee as substitute lessee. (West Virginia Supreme Court of Appeals, Kanawha-Gauley Coal & Coke Co. vs. Sharp, 80 Southwestern Reporter 781.)

Effect of West Virginia Mine Law—The West Virginia Mine Foreman Law does not excuse a mine operator from liability for injury to an employee, resulting from failure to use due care to provide reasonably safe appliances and places of work, except insofar as the duty is devolved upon the foreman by such law. A mine owner is liable for death of an employee who came in contact with an uninsulated wire carrying a heavy electric voltage, if the employee did not know of the existence of the danger and was killed while engaged in the line of his work. (West Virginia Supreme Court of Appeals, Humphreys vs. Raleigh Coal & Coke Co., 80 Southeastern Reporter 803.)

"Independent Contractor" and "Employee" Distinguished—A person who was engaged to move a water tank for a coal company at an agreed price was an independent contractor, and not an employee in the sense that the compan[illegible]ld be liable to him for injury while doing the wor[illegible]ough rule which requires an emplo[illegible]nen [illegible]asonably saf[illegible]on- [illegible]on- [illegible]om [illegible]es. [illegible]al [illegible]- [illegible] [illegible]e

cepted, although not measured nor paid for. Held, that the deceased miner was an employee of the company, so as to render it liable for any failure to use reasonable care to maintain his working place in safe condition; that it was negligence to fail to support the roof after notice that it was in a dangerous condition; and that the company cannot rely upon any negligence of a co-employee of the decedent, since the fellow-servant doctrine does not apply to an injury resulting from an employer's breach of a nondelegable duty. The court said: "The work of driving the entry beyond the end of the track was continued. After removal of the coal for a short distance beyond, a blast was fired in the overhanging slate, which resulted in leaving the débris to be removed; and at the time of the accident deceased was engaged in carrying pieces of this slate to, and loading them upon the car. It is a mistake to suppose, as counsel do, that the work deceased was doing, within the space about the car where he was killed, was either opening that place for work or making it safe. It should constantly be remembered that the work of the deceased within that space was simply to use it as a passageway to carry material to the car; and the decisions upon which counsel rely are inapplicable for that reason." (United States Circuit Court of Appeals, Sixth Circuit; Big Hill Coal Co. vs. Clutts; 208 Federal Reporter 524.)

Substitution of Leases—Damages for Breach by Lessee—When a new coal-mining lease is substituted for a pre-existing one, all liabilities accruing up to the time of the making of the new lease still remain governed by the original contract, in the absence of agreement to the contrary embodied in the substituted lease. In suing to declare forfeiture of a lease on account of the lessee's failure to pay royalties and to prosecute work with reasonable diligence, the lessor is entitled to recover damages sustained by him on account of the breach. (Alabama Supreme Court, Pollak vs. Stouts Mountain Coal & Coke Co., 62 Southern Reporter 531.)

Contributory Negligence of Injured Miner—A lignite coal miner, injured through fall of a mass of clay from the roof of the room where he was working, cannot recover against his employer where it appears that, although it was his duty to examine the roof and to remedy any discoverable defects, he failed to do so, and that his injury is directly attributable to such contributory negligence. (North Dakota Supreme Court, Jackson vs. Chase, 144 Northwestern Reporter 235.)

Proof of Agency—When one sued for the price of coal interposed a defense that plaintiff was estopped to recover because it had held the agent, from whom the purchase was made and against whom defendant had a personal counterclaim, out as owner of the coal, the burden was on defendant to establish that defense, and not on the plaintiff to show that defendant knew or ought to have known that the agent was acting as such. (Wisconsin Supreme Court, Pennsylvania Coal & Supply Co. vs. Schmidt, 144 Northwestern Reporter 283.)

Right to Recover Statutory Penalty Not Assignable—In recently deciding that, under the West Virginia statute, which prescribes a penalty of $500 for mining coal within 5 ft. of line of adjacent land, a claim for such a penalty is not assignable, the Supreme Court of Appeals of that state said: "Obviously the penalty given by the statute here in question is not intended as compensation for coal taken or damage to property. It may be incurred without the taking of any coal from the land of the party entitled to sue. The taking of any coal at all within 5 ft. of the division line, and out of land belonging to the taker himself, inflicts the penalty. . . . . The enactment of it seems to have been nothing more than an exercise of the police power of the state. . . . . It does not stand in lieu of the right of action for injury to the land by the mining of coal therefrom, or a right of action for the value of coal taken. . . . An assignee of such person is clearly not the person injured. . . . It does not say the person injured, or his assignee, may sue. It is a highly penal statute, and falls under the rule of strict construction. Such statutes do not include anything beyond their letter, even though within their spirit. . . . Assignability of such claims encourages litigation and strife. . . . . Public policy forbids the conversion of penalties into commodities or assets." (Wilson vs. Shrader, 79 Southeastern Reporter, 1082.)

Discussion By Readers

Widths of Opening and Pillar

I want to thank COAL AGE for the publication of my inquiry and the answer given in the issue, Feb. 28, p. 379. Following the suggestion made that some important data had been omitted in my last inquiry and for the information of readers who may further discuss this question, I desire to give the following items:

The coal of the upper seam is a hard bituminous variety and, like that in the lower seam, is unaffected by exposure to air. The seam is from 40 to 48 in. in thickness, and free from impurities; it is underlaid with a hard bottom of sandy shale and likewise overlaid with a hard sandy shale varying from 10 to 30 ft. in thickness. The entire cover overlying the upper seam ranges from 50 ft. at the outcrop workings to 1000 ft. in the mountain. This cover is composed mostly of shale, sandstone and thin seams of coal. Both coal seams pitch about 2 per cent. into the hill.

In the working of the lower seam, no mud partings or slips have occurred thus far, except in outcrop work and when passing under small streams under light cover.

All the coal in both seams is undercut with chain machines and blasted with Monobel powder. No gas has yet been found in the upper seam and only small quantities have appeared in the lower seam. The lower seam has made but little water and this follows up the working face at the dip. There is little or no water in the upper seam, which is practically dry. I shall be glad to see these conditions further discussed by readers who have had experience under similar conditions.

THOMAS C. MILLER, Engineer.

Benham, Ky.

Safety or Refuge Chambers in Mines

Letter No. 1—The article presented by Charlton Dixon, COAL AGE, Mar. 21, p. 498, drawing attention to the need of providing safety or refuge chambers in mines, should not be passed by lightly. I heartily indorse all that he has said in that article.

Going back and recalling past experience, we find that in the Cherry (Ill.) mine explosion, which occurred Nov. 13, 1909, twenty men saved themselves by withdrawing into an improvised refuge chamber from which they were rescued, a week later. This incident alone emphasizes the importance and practical use of providing such refuge holes, at convenient points in every mine.

If I am not mistaken, some of the mines, in European countries, have provided such safety chambers. The idea is not new, but Mr. Dixon deserves much credit for drawing attention to its importance and suggesting that the matter be taken up and thoroughly discussed. I earnestly hope that much good will come from such a discussion.

It is a matter of common observation that the large majority of the victims of mine explosions have not been killed outright by the force of the explosion, but have been overcome, later, by the afterdamp. In many cases, there is evidence that these men have lived for hours or even days after the explosion took place. In such case, who would deny that a refuge chamber located in the live workings, would have been the means of keeping the men alive until help could reach them.

In the campaign for "Safety First," is it not true that we are overlooking some of the most important points to be considered. Mine explosions are of sufficient frequency to demand the most careful consideration, and every possible preparation should be made to overcome their dread effects. We may say that fully 90 per cent. of the explosions of gas and dust in mines occur at or near the working face, in what are called the "live workings." Large mines are, as a rule, divided into districts that are more or less separate. Each district should have a refuge chamber. As far as practicable, the districts should be separated from each other by a continuous pillar of coal, where the room-and-pillar system is in use. In my opinion, refuge chambers should be provided for in the original layout of the mine. No mine plan should be complete without this provision. They are of as much importance as any other features of the mine.

I would suggest that a refuge chamber should be driven about 18 or 20 ft. wide and, say 70 ft. long, so as to accommodate at least 100 men. The chamber or room should be driven in solid coal, without cut-throughs connecting it with other openings.

A refuge chamber can be fitted up and furnished, according to the judgment of the men in charge; but, in any case, each refuge chamber should be reached from the surface by boreholes, through which air, water and food could be supplied to the men entombed therein. There should be casks for holding water, a sanitary closet and disinfectants; and it might be expedient to have on hand a case of first-aid remedies, and, possibly, one or more sets of breathing apparatus. This last named equipment, together with oxygen tanks, etc., will not be considered by many as essential.

The main feature of the refuge chamber should be to provide a place where the men can be kept alive until rescued. It is most important that the chamber be provided with substantial doors that can be closed and sealed, to prevent the entrance of any poisonous gases into the inclosure.

The Certificate Law

Letter No. 24—The recent discussion in reference to the possible interchange of certificates of competency for mine foremen and firebosses has interested me much. The matter is under consideration, at the present time, with the board of examiners in this (Alberta) province.

I hold a mine manager's certificate of competency, granted me in Edinburgh (Scotland), in 1909. The new

mining law, in this province, that came into effect in August, 1913, reads as follows:

> The chief inspector of mines may sign and deliver a certificate, without examination, to any person holding a certificate from any other country, providing the board of examiners reports that the standard of training and examination required for the granting of such certificate is equivalent to that required for the granting of a corresponding certificate under this act.

I have made application to the examining board for a certificate of competency, to be granted under the law I have just cited and, at the present time, my application is under consideration by the board. It is my personal interest in this regard that has caused the discussion of this question to appeal to me very strongly.

ANDREW BARCLAY.

Bankhead, Alta., Canada.

Letter No. 25—It is quite generally admitted by mine workers that only practical men should be allowed to qualify for a mine manager's certificate. As I have been working in mines, from 10 years of age till now, I would naturally be expected to favor this view, which I do to a certain extent.

We must not forget, however, that one of the greatest boons known to mining was the work of a man who knew nothing of practical mine work. I refer to Sir Humphrey Davy, the inventor of the Davy safety lamp. It was Davy's knowledge of physics and chemistry that led him to this discovery so important in coal mining. It is quite possible that if the history of the development of the different types of safety lamps and other important features of mine equipment were known, it would be found that many of these were the work of men who knew little or nothing of mining. We are indebted to Galileo for much of our present knowledge of atmospheric conditions; to Torricelli, for the barometer; to Isaac Newton, for the knowledge of the laws of gravitation, and to many others whose knowledge of science has affected the practical work of mining.

I believe that a man who has qualified and received a certificate of competency in one state, should be likewise qualified to hold a similar position in another state. His study of mining has acquainted him with most of the difficulties he is likely to meet anywhere. A man who understands the nature and danger of coal dust in the mines of Pennsylvania, will be capable of treating this matter in Colorado. In my opinion, it is a mistake to think that only local men understand the dangers and are capable of working the coal successfully in their several districts. It is probable there are many men in other districts who would be able to mine the coal more successfully than many of the men already acquainted with the local conditions in a certain mine or district.

I would state, as an example, in support of this opinion, according to Robert Peel, only one-third of the coal is being taken from a 30-ft. seam in South Staffordshire, and this seam is one of the best coals in England. Local talent does not show to advantage in this case. If the report be true, competent mining men from other localities have expressed the opinion that, by the adoption of a suitable method of longwall working, practically 100 per cent. of the coal could be taken from this seam. In support of their view, they refer to other thick seams worked by the longwall system, on the Continent, where most all of the coal is recovered. It is only fair to allow, however, that the failure to extract a larger percentage of coal is quite often due to the desire to obtain quick returns on the investment.

I cannot agree with the writer of Letter No. 23 that the mining law of Illinois, requiring that all candidates in examination must be residents of the state, "is right because it protects its own citizens." In New Zealand, a coal digger from Scotland or England is not allowed to dig coal till he has been two years in the mines of that country. It is not, there, a question of ability, as the men debarred are men who have dug coal all their lives. In parts of Germany, a boy going into the mine must push cars and do other work before he is allowed to learn how to dig coal. In India, a boy must follow the same occupation as his father.

Such restraining laws are common in foreign countries; they do not protect; but, by diminishing the opportunities, work hardships and destroy the ambition of competent men. The stagnation produced in the industries, by such laws, is plainly evident. As an excuse for looking to this country for a manager, Lord Hamilton is reported to have said, "There is something paltry about the British system, which tends to interfere with the mental activity of employees and reduces them to mere automatons, sacrificing merit to seniority."

I would favor the issuing of certificates of competency by the Federal government, as I believe this would lead to the adoption of a more uniform system of examination in the several states. The examination could be made to cover every phase in coal mining, and I believe would eliminate, to some extent, at least, favoritism in the granting of certificates.

I do not think that certificates should be granted to men who have no knowledge of mine gases, permitting them to take charge of nongaseous mines. Suppose, for example, marsh gas (CH_4) has never been found in the mines in a certain district, and a mine foreman employed in one of those mines knows nothing of mine gases. How would such a man be able to deal safely with a mine fire, when he is liable, then, to meet with two dangerous gases, carbon dioxide (CO_2) and carbon monoxide (CO). The latter may even prove explosive, making the conditions even more dangerous. Under such conditions, the mine foreman must be able to act at once and intelligently. He cannot wait for the inspector to arrive.

Referring to uniform state examinations, there could be no objection to giving questions that have a special bearing on local conditions in any state, provided this did not exclude other important questions. It is not long ago that mine foremen had little idea of the size of pump necessary to deal with a given quantity of water, in a given time. This and other like instances show the necessity of the examination dealing with all classes of mine work.

Speaking of the Federal government issuing the certificates of competency, it would not be necessary for them to hold the examination, which could be held, as now, by the state examining board, in conformity with the general rules and regulations laid down by the Federal government. But the certificates issued by the Federal government, on the recommendation of the local examining board, would make the holder of such certificate eligible for the position in any state.

ROBERT MCCUNE.

Dawson, N. M.

Fan Ventilation

Being much interested in the question of the ventilation of mines, the inquiry of D. J. Hopkins, Jan. 24, p. 180, in reference to the installation of a second fan to increase the circulation of air in the mine, attracted my attention. I believe the plan suggested by Mr. Hopkins to be entirely practicable, providing the air shaft is large enough to carry the amount of air required.

Before we can fully decide on the feasibility of the proposed plan, it is important to know the size of the upcast and downcast shafts as well as the size of the main intake and return airways, in any proposition of this kind. I would suggest that if the sectional area of the airshaft is sufficiently great both of these fans could be installed at the top of the shaft so as to work in parallel. This plan, however, would require the splitting of the air current at the foot of the shaft, in order to provide a separate current for each side of the shaft. In preference to this, I would, if possible, place each fan over its own air shaft.

In my opinion, a second fan, operating in parallel with the first, is of great value for the purpose of increasing the circulation in a mine; but, in no case, would I install the second fan as a "booster." In the installation of mine fans, it is important never to figure the capacity of a fan too closely, as it may and frequently does, happen that gas feeders are met heavier than what are expected and a greater air volume is required to properly ventilate the mine.

In all mine ventilation, I favor the splitting of the air current wherever this can be done to advantage. The method provides purer air at the face of each district, or section of the mine, and the gases generated in the several districts are carried at once into the return airway, without passing through other sections of the mine. Also, the velocity of the air sweeping the working face is much lessened, thereby reducing the friction of the air current and exposing the workmen to less discomfort owing to the strong draft. There is, also, less danger of the flame of the lamp being blown through the gauze where safety lamps are used. As stated in COAL AGE, Vol. 2, p. 335, the mine resistance is always decreased by splitting, provided the total sectional area of all the splits is greater than the sectional area of the air shaft or main airway; otherwise, the splitting of the air current will increase the mine resistance. My experience leads me to recommend that the plan suggested by Mr. Hopkins should be adopted.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

ADDITION OF DECIMALS

The addition of decimals differs in no respect from the process of addition previously explained. As before, figures of the same unit value must be written in the same column.

Rule—Write the decimal numbers to be added so that the decimal points of all the numbers will be in the same vertical line, and likewise the tenths, hundredths, thousandths, etc., in their respective columns. Then, beginning on the extreme right, add together the numbers standing in each consecutive column, proceeding as in the addition of whole numbers, writing the units figure of each sum in its respective column and carrying the tens figure, if any, to the next column on the left. When all the columns have been added, place a decimal point in the result under the decimal points of the numbers added.

The following examples will make the process clear:

0.314	0.468
0.40561	34.1095
0.3502	6.034
0.69	19.9823
0.0045	0.32
1.76431	60.9138

The right-hand columns will frequently contain only a few figures. As above, the addition of decimals will often produce a whole number and a decimal. The addition is always carried past the decimal point as though the latter did not exist, pointing off the figures in the sum, however, to correspond to the columns added.

SUBTRACTION OF DECIMALS

The process of subtracting one decimal number from another is the same as in the subtraction of one whole number from another.

Rule—As in whole numbers, write the lesser number under the greater, placing tenths under tenths, hundredths under hundredths, etc., annexing ciphers, if necessary, to make the decimal places equal in each number. Beginning on the right proceed as in the subtraction of whole numbers, and point off the result to correspond to the numbers subtracted.

Example—Subtract (a) 0.10475 from 0.293; and (b) 0.9706 from 1.04635.

Solution—

	(a)	(b)
	0.29300	1.04635
	0.10475	0.97060
	0.18825	0.07575

MULTIPLICATION OF DECIMALS

The process is identical with the multiplication of whole numbers, except for the matter of pointing off the product.

Rule—Ignoring, for the time, the decimal points, proceed as in the multiplication of whole numbers, disregarding any ciphers standing on the left. Finally, point off from the right of the product, as many decimal places as there are in both numbers, prefixing ciphers if required to complete the number.

The Coal Age Pocket Book

The following examples will illustrate the rule:

20.7654	.001764
3.42	.0256
415308	10584
830616	8820
622962	3528
71.017668	.0000451584

In the first of the above examples, there were four decimal places in the multiplicand and two in the multiplier, making it necessary to point off six places in the product. In the second example, there were ten places to be pointed off in the product, which contained but six figures, and it was therefore necessary to prefix four ciphers before placing the decimal point.

Multiplying by 10, 100, 1000, etc.—To multiply a whole number by 10, 100, 1000, etc., it is only necessary to annex as many ciphers to the number as there are ciphers in the multiplier. Thus,

$$1728 \times 100 = 172{,}800$$

To multiply a decimal number by 10, 100, 1000, etc., it is only necessary to move the decimal point as many places to the right as there are ciphers in the multiplier, annexing ciphers if necessary to complete the number. Thus,

$$0.4381 \times 1{,}000 = 438.1$$
$$0.004 \times 10{,}000 = 40$$
$$1.45 \times 100{,}000 = 145{,}000$$

DIVISION OF DECIMALS

The operation of division is the reverse of that of multiplication. The process is identical with the division of whole numbers, except for the pointing off of the quotient.

Rule—Ignoring, for the time, the decimal points, proceed as in the division of whole numbers, disregarding, as before, any ciphers standing on the left. Finally point off from the right of the quotient as many decimal places as those in the dividend exceed those in the divisor.

Example—Divide (a) 11.284 by 2.6; and (b) 35.1 by 0.156.

Solution—

(a) 2.6)11.284(4.34
104
88
78
104
104

(b) .156)35.100(225
312
390
312
780
780

When the divisor, as frequently occurs, contains more decimal places than the dividend it is necessary to annex ciphers to the dividend until it contains an equal number of decimal places and the quotient, to that point, will be a whole number, as shown on the right, above.

Examination Questions

Miscellaneous Questions

(Answered by Request)

Ques.—What thickness of barrier pillar does the law of Pennsylvania require along a boundary line?

Ans.—The Pennsylvania anthracite-mine law compels the owners of adjoining coal properties to leave or cause to be left a pillar of coal, in each seam that is worked by them, along the line of an adjoining property. The pillar of coal so left shall be of such width that, taken in connection with the pillar to be left by the adjoining property, it will be a sufficient barrier for the safety of the men working in either mine, in case the other mine should be abandoned and allowed to fill with water. The law states that such width of pillar is to be determined by the engineers of the adjoining property owners, together with the inspector of the district.

Although the law does not specify the actual thickness or width of barrier pillar, the rule in common use in the anthracite region has been to add 5 ft. to 1 per cent. of the depth of the pillar below the natural drainage level, and multiply this sum by the thickness of the seam, in feet; the product is the required width of barrier pillar, in feet.

The bituminous-mine law of Pennsylvania (Art. 2, Sec. 2) requires that when the workings of a mine approach within 300 ft. of the boundary line between that and an adjoining mine, the operator or superintendent of the mine first mentioned shall make application to the inspector of the district for information as to the proximity of the workings of such adjoining mine or mines.

If said adjoining workings are within 300 ft. of the boundary line at their nearest approach thereto, the inspector must notify said operator or superintendent, whose duty and right it is to enter and survey the said adjoining workings, on the written authority of the inspector. Such survey must be placed on the mine map kept at the office for the use of the mine officials and the inspector, and for the inspection of any person working in said mine, as desired, but in the presence of the superintendent or mine foreman.

Ques.—How many cubic feet are there in a piece of coal $23 \times 19 \times 8$ ft.; and what is the weight of the coal if its specific gravity is 1.6?

Ans.—The cubical contents of this block of coal is $23 \times 19 \times 8 = 3496$ cu.ft. To find the weight of the coal, multiply the cubic contents by the weight of 1 cu.ft. of water (62.5 lb.) and that product by the specific gravity of the coal; thus $(3496 \times 62.5 \times 1.6) \div 2000 = 174.8$ tons.

Ques.—(a) Find the pressure per square inch on the tamping of a 3-in. drill hole tamped with 3 ft. of clay, when 6 lb. of gunpowder have been ignited in the hole. (b) Give the velocity of a wind from such a pressure when the energy of the charge has all been spent on the atmosphere, in a 6 by 8-ft. entry, neglecting resistance, the atmospheric pressure being 14.7 lb. per sq.in.

Ans.—We assume that the question refers to common black blasting powder instead of "gunpowder." The volume of the gaseous products of the explosion of black blasting powder, measured at a temperature of 32 deg. F. and a pressure of one atmosphere, equals 360 times the original volume of the powder. Since the solid products of the explosion form one-third of the original volume of the powder, the 360 volumes of gaseous products are confined, at the moment of explosion, in two-thirds of the space occupied by the original powder. But since the pressure of gases varies inversely as their volume, for a constant temperature, the pressure at the moment of explosion, due to the compression of the gases produced, is $360 \times {}^3/_2 \times 14.7 = 7938$ lb. per sq.in., measured at a temperature of 32 deg. F.

The pressure at the moment of explosion, however, is still further increased by the rise of temperature from 32 deg. F. to that caused by the combustion of the powder in the drill hole. If this combustion were instantaneous, the temperature produced would be somewhat above 6000 deg. F. The explosion of black powder, however, is never instantaneous; and, in the case of blasting powder, the grains of powder burn slowly, the ignition spreading from one grain to another and the heat being developed gradually. This action produces a gradually increasing temperature and pressure in the drill hole, until rupture takes place in the coal and the gases are permitted to escape into the atmosphere. Owing to these conditions, the temperature of the explosion of black blasting powder in a drill hole, rarely exceeds 2000 deg. Fahrenheit.

The pressure due to this temperature would then be per sq.in.

$$7938 \times \frac{460 + 2000}{460 + 32} = \frac{7938 \times 2460}{492} = \textit{say } 40{,}000 \textit{ lb.}$$

(b) It is absurd to ask for the velocity of wind produced in a 6 by 8-ft. entry by the explosion of a given weight of blasting powder in a drill hole, as there is no method by which this can be calculated; and, indeed, the results would vary greatly in fact and give no practical information.

It is possible, however, to estimate the theoretical velocity of the gases projected from a drill hole, under the pressure created by the explosion of the powder, the degree of accuracy depending on the correctness of the calculation of the pressure produced, which is then only approximately true at the initial point and moment of explosion.

A calculation based on the average composition of blasting powder, and the relative volumes of gases produced, shows that these gases may have a density 18 times that of hydrogen gas, at normal temperature and pressure. The theoretical velocity, due to a pressure of 40,000 lb. per sq.in., for this density of the gases, as calculated from the formula $v = \sqrt{2\,g\,h}$, is practically 60,000 ft. per sec., an almost inconceivable velocity.

Inquiries of General Interest

Path of Crankpin of an Engine Driver

I am sending a question to COAL AGE, in hopes that a correct answer can be given. There has been a considerable difference of opinion expressed, here, in reference to the answers obtained to this question. The person giving the problem states that the correct answer is 16.781+ ft. Although this question is not strictly in the line of other questions answered in COAL AGE, we would like to have the correct solution published, and believe this would be of interest to all, at least as a mental exercise. The question is as follows:

What distance does the crankpin on a locomotive wheel travel while the wheel makes one revolution running on the rail; assuming the wheel to be 5 ft. in diameter and the crankpin to be midway between the center and the tread of the wheel?

J. J. STONE.

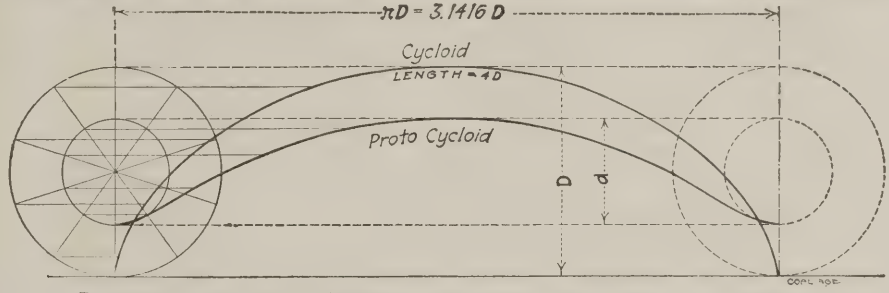
Johnstown, Penn.

We are glad to give the solution to this question or any other that does not involve the use of higher mathematics. We believe every student of mining is benefited by the study of simple mathematics.

The path described by the crankpin of an engine driver is a curve known as a "prolate cycloid." It is the path described by any point within a circle when the circle rolls upon its circumference, on a plane surface, the plane of the circle or plane of revolution being at right angles to the surface on which it rolls.

Any point in the circumference of the circle will describe a path known as a "cycloid." The length of this path or the length of the cycloid, for a single revolution, is always four times the diameter of the circle. But, it is clear that when the circle makes one revolution, the center of the circle moves a distance equal to its circumference. The path described by the center of the circle is, therefore, a straight line parallel to the plane on which the circle rolls, and its length (πD) is equal to the circumference of the circle.

It is equally clear that the path described by any point lying between the circumference and the center of the circle must have a length less than $4\,D$ and greater than $\pi\,D$, or $3.1416\,D$. To determine the length of this path, or the length of a "prolate cycloid," by exact mathematical calculation, is a complicated process. It is, however, expressed very approximately by the following formula:



$$L = \pi D + 0.86\left(\frac{d}{D}\right)^2 D$$

in which L equals the length of the path; D, the diameter of the circle; d, the diameter of the crank circle, all in feet or all in inches. In the present case, $D = 5$ ft.; $d = 2.5$ ft.; and the length of the prolate cycloid described by the crank pin, in one revolution of this wheel, is approximately

$$L = 3.1416 \times 5 + 0.86\left(\frac{2.5}{5}\right)^2 5$$

$$= 5\,(3.1416 + 0.86 \times \tfrac{1}{4}) = 16.783\ ft.$$

The accompanying figure shows the cycloid described by a point in the circumference of a wheel whose diameter is D, and the prolate cycloid described by the crankpin, the diameter of the crankpin circle being d, which in the present case is one-half of the diameter of the wheel. The dotted circle shows the position of the wheel after making one complete revolution.

ILLUSTRATING THE CYCLOID AND PROLATE CYCLOID CURVES

Longwall, Packwall System

I beg to ask the readers and correspondents who have already given some valuable information concerning longwall-retreating methods, the following question:

Can the common packwall system of longwall mining with two or three sets of posts at the face, be made to successfully replace the room-and-pillar system, in a mine that has advanced about two miles. The coal is semi-bituminous and lies in a basin or syncline that is about 7 miles wide from north to south. The seam varies from 4 ft. to 4 ft. 6 in. in thickness, and the depth of cover from 300 ft. to 700 ft. at the middle of the basin. Above the coal is a blue rock from 4 ft. to 8 ft. thick, overlaid with a fine-grained sandrock and sandy shale that do not break over a long distance. The immediate bottom of the seam is a soft slate 9 in. thick, beneath which is a thin stratum of coal of the same thickness. Underneath that is a soft fireclay, which has a tendency to heave.

CONSTANT READER.

Windber, Penn.

[We shall be glad to have those interested and experienced in longwall work discuss this question of how a longwall face can be successfully started at the face of room-and-pillar workings that are fully developed. State the chief points to be considered before any attempt should be made to change the plan of working from the room-and-pillar system already developed, to the longwall method of the packwall system of mining. State what advantages may be expected to be gained by making this change.—ED.]

Coal and Coke News

Washington, D. C.

The Interstate Commerce Commission has handed down a decision in the case of Campbell's Creek Coal Co. vs. the Ann Arbor R.R. Co. in which it further defines the portion of the Interstate Commerce act relating to the furnishing of cars and switching connections, and holds that the portions of the act relating to these two topics must be considered together. It also contends that the application of main line rates to points on the Kanawha & West Virginia and the coal and coke railroads, while they were denied to the complainant company, was undue and unreasonable prejudice which should be corrected either by canceling the main line rates to points on the lines mentioned or by establishing the main line rates as jointly with the Campbell's Creek region.

The substance of the complaint which gave rise to this case is found in the fact that the Campbell's Creek R.R. is a common carrier engaged in interstate commerce. The railroad is entirely separate from the Campbell's Creek Coal Co. Neither company owns the stocks or bonds of the other, and they are managed and operated separately. The road is distinct from the plant facilities, namely, the mine cars and locomotives and the tracks ramifying through the mines and leading to the tipples of the coal company, all of which are owned by the Campbell's Creek Coal Co. Complainants have sought in vain from defendants, the Kanawha & Michigan and its connections, the establishment of through routes and joint rates for shipments of bituminous coal from points on the line of the Campbell's Creek R.R. to the various destinations mentioned in Kanawha & Michigan tariff I. C. C. 31 and supplement 15 thereto. The joint rates sought are those applying from points on the main line and branches of the Kanawha & Michigan Ry. and points on the line of the Kanawha & West Virginia R.R. Because of the refusal of these rates shippers on the Campbell's Creek R.R. are compelled to pay in addition to the main-line or Kanawha district rates, which apply from Dana, the local rate of the Campbells' Creek R.R. to Dana, which is 15 cents per ton.

A decision has also been handed down in the case of the Hughes Creek Coal Co. vs. the Kanawha & Michigan Ry. Co., and in the Kelly's Creek Colliery Co. vs. the same. In this decision it is held that the complainant's request for through routes and joint rates between stations on the Kanawha & Michigan Ry. and its branches and the points specified in the complaint in eastern and southeastern territory on the lines of the Chesapeake & Ohio and its connection should be granted, the rates charged to be not in excess of those now applying to these destinations for shipments from the mines on the Chesapeake & Ohio. The charge that since the Chesapeake & Ohio and the Kanawha & Michigan are practically one road it is unjustly discriminatory for them to deny the Kanawha & Michigan lines access to markets which have been made available for Chesapeake & Ohio mines is held not to have been established as the identity between the two roads is not regarded as having been proven. At present the coal from the mines on the Kanawha & Michigan has competitive rates—that is, rates which permit it to meet the competition from other fields—only to certain territory in the northwest where the competition is very strong. In Cincinnati it has a competitive rate only by one connection of the Kanawha & Michigan, the Baltimore & Ohio Southwestern, with a resulting limited number of deliveries. The coal from the Chesapeake & Ohio mines on the other hand has not only an extensive market in the northwest, including all deliveries in Cincinnati, but also competitive rates to the Atlantic Coast and to markets in the East and Southeast. When rates from the mines are spoken of what is meant is rates from the stations on the main line or branches of the defendant railroads from which the mines ship their coal.

The Committee on Lands of the Senate has reported the administration bill for the leasing of coal mines in Alaska in a different form from that in which it was referred to the Committee on Mines before that committee was discharged from consideration. In the new form the bill provides for the designation of certain reserve areas in Alaska which are to be mined under the direction of the President whenever necessary while in all other areas it is provided that the lands "shall be divided by the Secretary of the Interior into leasing blocks or tracts of forty acres each, or multiples thereof, and in such form as in the opinion of the Secretary will permit the most economical mining of the coal in such blocks, but in no case exceeding two thousand five hundred and sixty acres in any one leasing block or tract; and thereafter, subject to any prior valid existing rights, which said rights may be perfected under the laws in force at the time the same were initiated, the Secretary shall offer such blocks or tracts and the coal, lignite, and associated minerals therein for leasing, and shall award leases thereof through advertisement, competitive bidding, or such other methods as he may by general regulations adopt, to any person above the age of twenty-one years who is a citizen of the United States, or to any association of such persons, or to any corporation organized under the laws of the United States or of any State or Territory thereof."

HARRISBURG, PENN.

"The legislature might just as well place a state tax on hard-shell crabs and exempt soft-shell crabs as to tax anthracite coal and not bituminous," said Major Everett Warren, of Scranton, in the Dauphin County court, sitting in this city on Mar. 25, in the suit to test the constitutionality of the anthracite coal tax. "The taxes in this state must be uniform, and the legislature did not keep to the classification which it should have followed. By the same simile it might as well have taxed red-headed men only because it can tax men."

Attorneys for the state and for several cities and boroughs declared that the People's Coal Co., of Scranton has shown no grounds for relief in equity in bringing the suit to test the constitutionality of the tax. The Scranton company is understood to represent a number of other anthracite producers and the suit, which was filed in January, will probably go clear up to the highest court of the state, and, possibly, to the U. S. Supreme Court, for adjudication.

President Judge Kunkel, who has sat in a number of famous suits to test constitutionality, was on the bench and the People's Coal Co., was represented by Major Everett Warren, of Scranton, Ex-Judge F. W. Wheaton, of Wilkes-Barre, and Ralph Reimer, general counsel of the People's Coal Co. Deputy Attorney General Hargest took charge of the case for the state. Seated at the state's table were a number of attorneys, representing various cities and boroughs.

The plaintiffs offered an amendment to the bill in equity at the opening of the court, charging that in addition to the reasons advanced some time ago for declaring the law unconstitutional the law was local legislation and that, being such, it was illegal because it had not been advertised.

Speaking for the state, General Hargest declared that the company had failed to show in its bill any grounds for relief in equity. The law provides a way for a test without invoking the extraordinary powers of a court of equity, because there are laws which allow appeals from tax settlements by the state which are used every day and which have been employed to secure adjustment of cases involving millions of dollars. General Hargest attacked the averments that the law offended against the constitution of the United States and of the state because of loss as being not well taken. Taking up the contention that the law was a "makeshift" and that a portion of the income might be used for payment for surface damages, he said that such a statement was "scandalous" and that the plaintiff had no right to attack the state on such an assumption. As to the great and irreparable injury which it was averred the company would suffer if compelled to file reports and comply with the law by Feb. 1, he said, that the statement was absurd because the companies had complied with the law and had filed reports. He remarked that the plaintiff does not come into court with such clean hands as it should have in equity.

The deputy attorney general went through the bill and attacked each averment. On the amendments he said that if the tonnage tax was local legislation, then all anthracite laws were also local.

In answering the demurrer of the state to the suit Major Warren made the remark about the hard- and soft-shell crabs

to support his contention that the classification clause had been ignored. He argued that the Dauphin County Court can take jurisdiction in the case and asked what earthly difference it made whether the case was settled on the legal or equity side of the court. Equity, he asserted is the place to settle the integrity of the law and cited proceedings in valuation of coal lands in Lackawanna and Luzerne counties in support of his contention.

Taking up the answer of the state that there was impertinent matter in the bill, he denied it and said that if the Supreme Court could go into the history of the school code the bill could go into the history of the act, and if the state's highest court called the code "a subterfuge" in a dissenting opinion the present act might be styled a "makeshift" in a bill. Indications were given that the case may go to the United States courts by reference made by the counsel for the coal company that all but 8 per cent. of the anthracite is sold outside of the state.

The law, he said, added a tax to coal and did not relieve the land from local taxation; it has a defective title, and the penalty for failing to make a report he styled "a club." Throughout the argument the Major resented the attitude of the state and once said that the state was to blame for the delay in getting a hearing because of length of time taken to file its demurrer.

The main argument against the constitutionality of the act was that it violated the classification clause, the Major contending that it draws a hard and fast line between anthracite and bituminous. Taxation, he said, must be uniform and the coal produced in eight counties is to be taxed and that produced in twenty-eight others is exempted.

No decision is expected for a few days, probably weeks.

PENNSYLVANIA

Anthracite

Pottsville—The famous "barrier pillar case" one of the most important law suits ever appealed from the Schuylkill County court, was, on Mar. 23, decided in favor of Mine Inspector John Curran of the 18th district, who brought the suit to maintain the barrier pillar between the collieries of the Mill Creek Coal Co. and the Dodson Coal Co., at Morea. Inspector Curran feared that if the barrier was tampered with, subterranean bodies of water might break through it and drown hundreds of miners. He therefore got an injunction against the Mill Creek Coal Co. to prevent interference with the pillar. As this would prevent the mining of vast bodies of coal, the company appealed. The size of the barrier was finally fixed at 300 ft., the higher court sustaining this decision.

Wilkes-Barre—Charging that the Wilkes-Barre Anthracite Coal Co., is unlawfully removing coal from beneath private property on North Franklin and Union Sts., property owners in the Fourth Ward have filed eight separate suits against the company to restrain further mining under the tracts, and compensate the owners for the coal removed. Judge O'Boyle granted preliminary injunctions in all the cases.

Avoca—Two hundred men and boys, employed in the D & H. Co.'s Langcliffs colliery refused to go to work on Mar. 26 on account of not having received their proper pay, so they claim. Superintendent Lovering had a conference with the employees and made an effort to amicably adjust the matter, but without success. The men are still out, but hope for a settlement in a day or two.

Mt. Carmel—More than 1500 miners formed in line on the night of Mar. 28, and marched from the Methodist Episcopal Church to the tabernacle where Dr. H. W. Stough, the evangilist, is conducting services. Headed by State Mine Inspector Ben. I. Evans, the miners paraded over the streets carrying banners and American flags. It was "Miners Night" at the tabernacle. Evangelist Stough spoke at length upon the great dangers encountered by those who work underground for a living. Nearly 100 miners "hit the trail."

Mahanoy City—Twenty feet of a Maysville schoolyard were swallowed in a mine breach on Mar. 23. The depth of the hole is not known. The five schools in the building did not hold sessions the next day. Old workings of the Gilberton Colliery honey comb the section. If the surface shows further evidence of settling the building will be abandoned.

Kingston—John W. Wier, a brakeman employed by the Kingston Coal Co. who was in the cab of a small locomotive, that was completely engulfed in a mine cave on Mar. 23, escaped by jumping. The cab was demolished and the engine toppled over on one side. The locomotive was righted on a temporary track and it required the combined power of four other small engines to haul out of the cave.

Shenandoah—The body of George Isgate, 55 years old, who was buried alive in the caving in of old workings of the Thomas Colliery on Mar. 20, was recovered on Mar. 25, wedged in between coal, timber and slush 500 ft. below the surface. The second victim, John Decrish, an 18-year old youth, was found only five ft. away. Both bodies were badly mangled. The wife of Isgate, the mother of seven children, is in a critical condition and may die.

Treverton—The Pennsylvania Colliery, operated by the Susquehanna Coal Co., on Mar. 24, was the scene of a thrilling accident, when three miners were probably fatally injured, all having their skulls crushed by runaway cars. The loaded cars had been sent up a slope. The three men were awaiting the arrival of the empty cars at the bottom of the slope. As the cars reached the top, the side hooks, to which the rope and chain were attached pulled out, and both cars ran down the 900-ft. slope at terriffic speed. They remained on the tracks to the bottom, where they were demolished. The men were caught in the débris.

Bituminous

Monongahela—The Black Diamond mine of the Pittsburgh Coal Co., which was closed on Mar. 6, due to the burning of the river and railroad tipples, resumed operation last week. The tipple in use is a temporaory structure; the work on the permanent river and railroad tipples will be started at once, and pushed to completion.

Connellsville—Coke traffic was seriously interrupted during the past week by a strike of 6000 yard employees of the Monongahela division of the Pennsylvania R.R., who walked out early on the morning of Mar. 21, because the company had announced its intention of dropping one man from each of the yard crews. For several days it was impossible to move freight, but the company expects to have conditions at normal within a short time. The railroad brotherhoods have repudiated the action of the men in quitting work, and so far the strikers have been unable to enlist the support of the employees of other divisions. Brotherhood officials have sent word to men on other divisions who have been furloughed because of slack business to apply for the strikers' places.

Scottdale — The Valley works of the H. C. Frick Coke Co. was abandoned recently and wiped off the list as an operation. The coal has been exhausted and there is little possibility of the coking situation causing a condition that will entail firing the ovens at some future time to burn coal shipped from elsewhere. All the horses and mules have been shipped to other mines in the region. Many of them had never worked in any other mines. Mine Foreman Edward Quinn goes to Broad Ford it is said.

NEW YORK

Buffalo—The annual meeting of the Allegheny Operators' Association was held here on Mar. 26, at which President C. P. McCafferty and Secretary-Treasurer George E. Henry, of East Brady, were reëlected. A committee, consisting of E. C. Roberts, W. D. Ward and J. R. Brady, of Buffalo, and A. J. Watson and L. B. Lewis, of Pennsylvania, was appointed to meet the miners at East Brady after the close of the Central Pennsylvania meeting. The meeting was first set down for the 31st, but it was afterward learned that the other meeting would not adjourn in time.

KENTUCKY

Lexington—It has been announced that the annual meeting of the Kentucky Mining Institute and the state first-aid contest, which has become a regular feature of that meeting, will be held here May 8 and 9. The committee in charge of the first-aid work hopes to secure from the Bureau of Mines one of their explosive galleries for the purpose of demonstrating explosions of various sorts, both of coal dust and of blasting powders. An interesting program is being arranged, which will be made public in a few weeks.

Jenkins—General Manager Everett Drennen, of the Consolidated Coal Co., returned this week from Washington, where he was successful in obtaining the introduction by Representative Langley, of Kentucky, of a bill appropriating $50,000 for a Federal mine rescue station at Jenkins. Dr. Joseph A. Holmes, director of the Bureau of Mines, will give his support to the measure, the volume of the coal operations around Jenkins making the propriety of establishing such a station obvious.

OHIO

Gallapolis—Seven loaded coal barges of the Pittsburgh Coal Co., consigned for Louisville, were sunk near Gallapolis, Ohio, last week, causing a total loss, as no insurance was carried.

Columbus—J. M. Roan, Ohio safety superintendent, has given out a statement showing the benefits of his safety campaign during the past three months. For the first quarter of 1914 there were 25 fatal accidents in Ohio, as

compared with 32 for the corresponding quarter in 1913. The number of other accidents also showed a marked decrease. Many of the fatal accidents were due to the dangerous "draw slate" found in the eastern Ohio district. There was but one fatal accident in the Hocking Valley proper, one in Jackson district, one in Massillon district and one in Pomeroy Bend.

The wage situation in Ohio is in the most muddled condition in years. Neither the operators nor the miners are sure of their positions, and almost everyone anticipated the suspension of operations on Apr. 1. In fact, most of the operators had made active preparations for closing down for from 30 to 90 days time. Coal for fuel purposes had been stored and the mines generally cleaned up.

The mine-run law will not become effective until May 15 or 20, when the time limit for filing a referendum petition is over. Thus there is 45 days yet to consider the matter and to take any action desired to test the constitutionality of the new law.

Summing up the situation, Ohio operators to a man stand for a wage agreement which will not increase the cost of mining coal. They do not believe that the announced rate of $71^{46}/_{100}$c. per ton on the mine-run basis will be equitable as this is expected to increase the cost of mining from 3½ to 5c. a ton in Ohio fields.

Everyone is "up in the air" so to speak and there is much confuson over the issues at stake.

INDIANA

Petersburg—E. E. Kelsey has been appointed receiver for the J. M. C. Coal Co., which operates the mines at Massey, seven miles south of this city.

Jeffersonville—The larger towboats on the Ohio River have left their tows of empty barges, which they were bringing from New Orleans, and are being rushed to this point where 150 barges loaded with coal are waiting to be taken south, having been brought here by the smaller boats of the upper Ohio. On the recent rise of water 200,000 tons have been brought from Pittsburgh where the river has now fallen too low for further shipment.

Terre Haute—The United Mine Workers of District 11, which includes all the Indiana fields, except the Block mines, met here Thursday, Apr. 2, to consider the wage scale to be submitted later to the Operators' State Association in a joint conference. The Indiana miners will continue work for the present.

ILLINOIS

Springfield—Employers of labor and mine owners have had all doubts removed as to the validity of the Illinois compensation act by a recent decision of the Supreme Court, which sustains the act, both as passed in 1911 and 1912. Up to this time many operators refused to enter their acceptance of the act, doubting its validity.

Springfield—The operators in the 3rd District have elected an executive committee and have appointed Daniel Clark Commissioner for their own organization, which in the past has been a part of the Illinois Coal Operators' Association. It is understood that they have passed a vote, expressing a desire to join the 5th and 9th District Operators' Association, and will have a full representation at the joint scale meeting between the operators and miners at Peoria this week.

Owing to the differences existing in the coal operators' circulars in the State of Illinois, it is likely that the 4th and 8th Districts will join with the 3rd District in an attempt to organize a Central Illinois Operators' Association, composing the above districts and also the 5th and 9th Districts.

MISSOURI

St. Louis—The operators of the 5th and 9th Districts, at their meeting in St. Louis on Saturday afternoon, Mar. 28, took no definite action relative to resuming operations pending the adjustment of the scale in Peoria the latter part of the week. It is understood, however, that practically all of the operators will offer the miners the opportunity of going to work on Apr. 2, and it will be up to the miners then either to go to work under the agreement which expires in Mar. 31 or remain out until a new agreement is signed up, which will be practically along the same lines as the agreement of the past two years. It is also understood that the matter of the 3rd District joining the 5th and 9th District Operators Association was taken under advisement.

KANSAS

Lansing—Warden J. D. Botkin, of the state penitentiary here, will recommend at the April session of the prison board of corrections that the prison mine be sold to a private corporation and that the 300 convicts now employed in the mine be given other work. Of the 817 prisoners in the penitentiary, fully one-third are suffering from tuberculosis, according to the prison physician. Mr. Botkin takes the attitude that the spread of the disease was caused by unfavorable conditions in the mine, not because mining itself is unhealthful, but because of the caliber of the miners in this case.

Pittsburg—A strike, the basis for which caused wide discussion in mining circles of Kansas, tied up mines Nos. 19 and 20 of the J. R. Crowe Coal Co., in this field, for twenty-four hours during the past week, before the trouble was adjusted and the miners returned to work. The walkout took place after "safety first" and "danger" signs had been posted at conspicuous places in the mines, at the instance of General Superintendent R. A. Gray, of the Crowe Coal Co., As soon as the placards were posted, union delegates demanded that they be torn down. Mr. Gray refused and the miners walked out. An investigation was held and brought out the fact that the miners feared that the posting of the signs would in some way interfere with compensation in case of injury. It was explained, however, that the mere placing of placards in and around mines would in no way effect the provisions or workings of the Kansas workmen's compensation law. When reassured on this point, the miners returned to work. The Crowe Coal Co. then carried out its plans to placard all of its mines with the signs, while other mining companies which had watched the situation with interest also started work along the same lines.

LOUISIANA

Buxton—A dust explosion in Mine No. 12, near here, resulted in the death of two men, and much damage to the property.

WASHINGTON

Seattle—Surplus coal lands on the Colville Indian Reservation in the State of Washington are to be classified and appraised by a commission, the appointment of which has recently been announced by Secretary Lane. The commission is composed of Bart Moore, ex-mayor of Waco, Tex., chairman; Theodore Bowdeau, of Washington State, and J. R. Sovereign, of Keller, Wash. This work was authorized by Congress.

FOREIGN NEWS

Toronto, Can.—The annual report of the Mines Branch of the Department of Public Works of Alberta for 1913, shows that the 289 coal mines in operation in that province produced 4,306,346 tons of coal, of which 2,374,401 tons were bituminous, 1,763,225 tons lignite, and 168,720 tons anthracite. The increase over the production of 1912 was 859,997 tons. About one million tons were exported to other provinces and the United States. Coke production amounted to 65,167 tons, for which 104,012 tons of coal were used. The increase of output during the past eight years has been approximately 500 per cent.

PERSONALS

Joseph Angelo, international organizer for the United Mine Workers of America, has been sentenced to four years' imprisonment for his part in the Nanaimo coal strike riots of last August.

Dr. S. R. Cates, owner of coal lands near Lubbock, Tex., will lease the land in the near future to operators. The find has attracted much attention because of the fact that two railroads run into Lubbock.

Alfred Burger, formerly superintendent for the George M. Jones Co., at Corning, Ohio, has been transferred to Bellaire, Ohio, as superintendent of the Pultney & Webb mines, also operated by the George M. Jones Co.

H. L. Forstbauer, secretary of the Lorain Coal & Dock Co., of Columbus, Ohio, resigned his position, effective Apr. 1. No successor has been appointed by the directors of the company. Mr. Forstbauer will move to Cleveland.

J. L. McNatt, a coal operator of Aurora, Mo., has been appointed commissioner of the Missouri mining exhibit at San Francisco in 1915. A $42,000 building will house Missouri exhibits at the exposition. Moving pictures of Missouri's industries, including mining, will be made and shown at the exposition.

Secretary B. F. Nigh, of the Michigan-Ohio-Indiana Coal Association, who has headquarters in Columbus, has filed a complaint, comprising 1500 words, with the Interstate Commerce Commission, protesting against charging for spotting of cars, as proposed by railroads. It is urged that the charge for spotting will place an unnecessary hardship upon coal shippers and dealers. The protest is made at the suggestion of the commission which invited an expression of opinion.

Rufeno Rodriguez, a Mexican boy who saved the lives of 165 coal miners at Lehigh, Okla., on Feb. 22, 1912, when the mine caught fire, will receive a Carnegie medal for his heroism. The boy, who was employed at the mine, ran to every section in which men were employed, warning them of the impending danger. All escaped without injury. While Rodriguez was one of several who learned of the fire, he was the only one who exhibited the courage to spread the news. Following the fire, he was placed in the School of Mines of Oklahoma at Wilburton by the United Mine Workers of America, District No. 21, and has received an education there. Decision to give him a medal was made following a report by a district inspector.

OBITUARY

Thomas M. Mitchell, aged 56, committed suicide recently, at his home in Corinth Township, near Marion, Ill. He became wealthy through sales of coal lands in Williamson County to several eastern capitalists.

Philip Kolb, vice-president of the Kolb Coal Co., died at the Deaconess Hospital in St. Louis on Mar. 27, following an operation. He was a resident of Mascoutah, Ill., and had been engaged in the mining business for twenty years, having active charge of the Kolb Coal Co.'s several properties. He is survived by a widow, a son, and a daughter.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC.

of Coal Age, published weekly at New York, N. Y., required by the Act of August 24, 1912.
Editor, Floyd W. Parsons, New York, N. Y.
Business Manager, William Le Baron, New York, N. Y.
Publisher, Hill Publishing Company, New York, N. Y.
Owner, Hill Publishing Co., 505 Pearl St., New York, N. Y.
Owners of 1% or more of Stock Issued.
John A. Hill, 505 Pearl St., New York, N. Y.
Fred R. Low, 505 Pearl St., New York, N. Y.
John McGhie, 505 Pearl St., New York, N. Y.
Fred S. Weatherby, 1600 Beacon St., Boston, Mass.
Frederick A. Halsey, 356 W. 120th St., New York, N. Y.
G. Eugene Sly, 50 Union Sq., New York, N. Y.
Frederick W. Gross, 215 E. 11th St., Erie, Pa.
Alfred E. Kornfeld, 114 E. 71st St., New York, N. Y.
Emma B. Hill, 80 Munn Ave., E. Orange, N. J.

The balance of the stock issued (less than 1% each) is owned by 69 employees, 3 ex-employees, and 14 others who are wives, daughters or relatives of employees.

Known bondholders, mortgagees, and other security holders holding 1 per cent. or more of total amount of bonds, mortgages or other securities. Mortgage on building held by Dime Savings Bank, Brooklyn, N. Y.

C. W. Dibble, Vice-President,
HILL PUBLISHING COMPANY.

Sworn to and subscribed before me this 24th day of March, 1914.

RICHARD L. MURPHY,
Notary Public.
(My commission expires March 30, 1915)

CONSTRUCTION NEWS

Youngstown, Ohio—Youngstown Sheet & Tube Co. will soon begin construction on a $300,000 coke plant, on the site of the old American Bridge Co.'s plant.

Baltimore, Md.—The Baltimore & Ohio R.R. has perfected plans for the installation of telescopic chutes at its new $1,000,000 coal pier at Curtis Bay. The chutes will greatly reduce the breakage of coal, it is claimed.

Central City, Ky.—The numerous coal operators in this section are interested in a project to build a large central power plant on Green river, near here, and to construct an electric interurban line as well, from Central City to Greenville and Drakesboro. Dr. W. H. Netherland, of Louisville, is largely interested, and the General Electric Co., of New York, has sent representatives to look into the matter.

Chattanooga, Tenn.—It is understood that the Durham Coal & Iron Co. has authorized the immediate construction here of byproduct coke ovens, which will be built in blocks of 30 and 60, with a view to adding blocks as required. The present plant will consume about 800 tons of slack coal a day, producing about 5,000,000 cu.ft. of gas. The first block of ovens will cost about $1,000,000. C. E. James, promotor of the Hales Bar power dam, is interested largely.

Whitesburg, Ky.—It is reported that the Illinois Central Railroad Co. has purchased the right-of-way of the new Cincinnati, Licking Valley & Virginia, for which a survey was made last year through Morgan, Magoffin, Johnson, Floyd and Knott counties, and terminating in Letcher county, and will construct the line, in order to give it a road into the coal fields of Eastern Kentucky and also a way into Cincinnati. The road will be about 250 miles in length, two-thirds of which will be through rich coal and timber lands. The Illinois Central is not now a factor in the Eastern Kentucky field.

NEW INCORPORATIONS

Toledo, Ohio—The Home Fuel & Supply Co. has been incorporated with a capital of $10,000 to deal in coal, among other things. The incorporators are D. B. Frisbie, R. W. Taylor, W. J. Kelly, J. D. Rhoades and A. A. Fair.

Barberton, Ohio—Papers have been filed with the secretary of state, reducing the capital stock of the Columbia Fuel Co. from $100,000 to $25,000.

Cedar Grove, W. Va.—Hackett Coal & Coke Co., of this place, has been incorporated for the purpose of mining coal, the capital stock of $75,000. The incorporators are Samuel Hackett, Floyd Hackett, Gertrude Hackett and H. C. Tompkins, of Cedar Grove, W. Va., and J. Edward Settle, of Fayetteville, W. Va.

Harrisburg, Penn.—The first railroad to be chartered since the public service company law went into effect on Jan. 1, requiring certificate of convenience from the Public Service Commission, is the Easton & Western R.R. to construct and operate a railroad four and a half miles long from Easton to Hope's Lock. The capital is $50,000 and the incorporators: George F. Baer, Reading; R. W. DeForest, W. G. Besler and T. B. Koons, New York; E. J. Fox, W. E. Chipman and Horace Leher, Easton. Mr. Baer is president.

Palmer, W. Va.—A charter has been issued to the Old Lick Run Coal & Coke Co. The authorized capitalization is $500,000, and the incorporators are J. A. Ballinger, Mullica Hill, N. J.; L. O. Krupp, Plymouth, Penn.; Burton L. Hill, Wilkes-Barre, Penn.; William T. Turner and M. C. Goddard, Philadelphia, Penn.

INDUSTRIAL NEWS

Paducah, Ky.—The new steam coal tariff of the Illinois Central R.R. Co., affecting the Western Kentucky district and points getting their coal from there, has been issued, effective Apr. 1, increasing the rate on coal to Paducah 5c., to Louisville 5c. and to Memphis 10 cents.

Columbus, Ohio—Application has been made by the Norfolk & Western R.R. for permission to issue $10,000,000 in equipment trust certificates for the purpose of buying additional coal cars for the line. The application was made to the Ohio Public Utilities Commission.

Smithfield, Penn.—A new Coke company is being formed to take over 140 acres of coal in Springfield township, and $150,000 is being subscribed by Smithfield and Uniontown capitalists, headed by H. R. Sackett, of this place. It is expected that the deal for the purchase of the coal will go through in a short time. If the company is organized, the coal will be coked at the Sackett works at Emma siding, along the B. & O. railroad. The Sackett coal is about exhausted.

Frankfort, Ky.—The Illinois Central Railroad Co. has filed with the Kentucky Railroad Commission an application to be freed from the operation of the long and short haul clause of the railroad law to the extent of making a 60c. rate on coal from Nortonville, Isley, Carbondale and St. Charles, Ky., to Hopkinsville, without lowering the rate to Princeton and other intermediate points. The reduction is desired in order to enable the company to compete with L. & N. coal to points between Nortonville and Hopkinsville, between which points a 50-c. rate is in effect. The Hopkinsville Business Men's Association is with the railroad in its request.

Coal Trade Reviews

General Review

Opening prices in anthracite create the customary spring rush, but some doubt prevails over the future. Tension in the soft-coal market entirely relieved by the abrupt change in the labor situation. Demand down to lowest minimum and operations heavily curtailed pending the opening of Lake navigation.

The new coal year is opening up actively on anthracite. There is a heavy movement in the coastwise trade, mines are working up to full capacity, and there is an urgent demand from buyers anxious to acquire all the tonnage possible at the minimum circular of the year. It is a customary April market, but there is a feeling in some quarters that the trade will experience a decided recession by midsummer.

The partial settlement of the bituminous wage scale finds the market flat, with new business down to an irreducible minimum. The movement is almost entirely on contract, spot sales are seldom heard of, and consumers on all sides are showing a notable lack of interest. It is believed that many buyers have been discounting the possibility of only a short suspension for some time by using up accumulated stocks. Contracting for the new period is behind the average, due probably to the insertion of clauses providing for advances proportionate with any increase in the wage scale.

With the adoption of the old scale in the Pittsburgh district, what small business there was, has practically all disappeared. Production has been running considerably ahead of consumption throughout the winter, and it is estimated that only about 50 per cent. operations will be the rule until lake navigation opens. It is claimed by some that consumption is steadily decreasing, and there is considerable coal reported on demurrage at outlying points.

Indications of an early agreement in adjoining states has brought business to a standstill in Ohio, in spite of the fact that there is every indication of serious trouble there. Mines have been working up to nearly full capacity, and there is an enormous tonnage on hand in different parts of the state. An unexpected heavy loading at the Hampton Roads piers has reduced the stocks on track down to about normal; the indications are that the March dumpings have exceeded those for either of the two preceding months of the year.

Considerable uncertainty prevails in the Middlewestern situation. However, the expiration of the old wage scale found prices unchanged from those prevailing for the past several weeks. There has been less anxiety shown over the situation than ever before just preceding a wage agreement. Little or no consignment coal is coming forward, showing that there is no disposition whatever to speculate on the possibility of a protracted suspension. Interest so far is centering entirely on contracts for the new year, but there is little business being done even in this department.

EASTERN MARKET

BOSTON

Hampton Roads coals dull outside of contract business. "Market cargoes" apear at distributing points and concessions are offered to move them. New contracts slowly being closed on the same lines as usual. Water freights dull with practically no inquiry. Anthracite cargoes begin to arrive on April billing.

Bituminous—The Pocahontas and New River market is barren of any new features. Aside from deliveries on contract there is practically no movement at all to this territory. Spot sales are seldom heard and on all sides there is a notable lack of interest. A few cargoes are waiting orders at Boston and Providence and the distributors are finding consumers extremely reluctant to take on supplies at current prices. Moderate concessions have been made to move such lots but the response is anything but favorable. Even the Georges Creek shippers are meeting with difficulty in disposing of cargoes.

An additional amount of contract business has been taken by Hampton Roads shippers for the season of 1914-1915; it is being negotiated on about the same lines as last year and through the customary channels. No effort is spared to secure such business on the part of rival shippers but the $2.85 basis has so far been reasonably well maintained.

The Pennsylvania grades are slow with mining at only what the market will readily absorb. At tidewater they are hardly a factor just now when there is so much pressure to sell Georges Creek, Pocahontas and New River. No shipper takes the chance of sending cargoes of Pennsylvania coal forward on the market; the operators are even shy of sending coal to the loading ports except on firm orders.

Water freights are extremely dull, 70c. being the rate on large tonnage, Hampton Roads to Boston with plenty of space offering. What spot business develops is being taken by shippers who control their own steam colliers.

Anthracite—April cargoes have already begun to arrive, particularly at the more distant points, which helps relieve the dealers whose stocks were getting very low. There seems to be a great plenty of April coal for the requisitions on hand, and predictions are being freely made that by the latter part of May the hard-coal trade will be as slow as the bituminous is now. Circular prices are in general the same as last year except as in the case of broken where the Pennsylvania state tax will this year be charged throughout on all shipments.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.90	2.92@3.02	
New York*	2.50@3.05	2.80@3.20	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.85
Boston†				3.63@3.78
Providence†				3.68@3.83

*F.o.b. †On cars.

NEW YORK

The tentative clearing up of the labor situation has eliminated any uncertainties in the soft-coal trade and the market is down to the lowest point for some time. Usual spring activity prevails in anthracite.

Bituminous—The local soft-coal market continues dull and flat. There was some last-minute demand from consumers who finally decided to stock up in anticipation of a suspension, while most of the operating companies also accumulated limited surpluses, sufficient to take care of current business. This resulted in full-time operations at the mines during the closing days of March, but there was no anxiety observable in the market at any time. Further evidence of depressed conditions is observed in the fact that there was a total absence of the customary speculative business, which ordinarily precedes a wage conference.

The future of the market is full of uncertainties. It was generally conceded that a more or less protracted suspension was desirable in order to clean up the surplus coal, and as indications now are that operations will not be seriously interrupted, a long drawn-out dull period seems inevitable. On the other hand, there are some conservative members of the trade who are of the opinion that the possibility of only a short suspension has already been anticipated by many of the large consumers who cut off current shipments before the first of the month and began using reserve stock. If this be the case, there will not be such a large surplus as was anticipated, and the trade should straighten out more rapidly than was expected.

Contracts are still being negotiated on the same basis as last year, or better, but the business is coming forward slowly. All negotiations of this character embody a clause providing for any increase in the wage scale; this uncertainty, together with the general slowing up in business, and the growing belief that the operators may eventually be compelled to recede from the new high-price level of last year were some of the influences causing the buyers to delay. Little spot business is being negotiated, but the market remains quotable on the same basis as last week, as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

Anthracite—The opening of the new coal year finds anthracite experiencing the customary spring activity, all the more important buyers endeavoring to accumulate as large stocks as possible at the minimum price of the year, which prevails throughout this month. The activity is, of course, centering particularly about the prepared grades. These are all in strong demand, and even under full-time operations the companies will not be able to fill all requisitions on hand for the current month. Pea size is in good supply, while buckwheat and rice are rather short and in strong demand. The cheaper grades of barely are in excess supply.

Apr. 1 being a holiday, production for the week was not up to full rated capacity. We quote the new opening circular prices, and the spot market locally on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$4.60	$4.60	$4.55	$4.55
Egg	4.85	4.85	4.80	4.75@4.80
Stove	4.85	4.85	4.80	4.80
Chestnut	5.10	5.10	5.05	5.05
Pea	3.55	3.45@3.55	3.50	3.35@3.50
Buckwheat	2.80	2.75@2.80	2.50@2.75	2.50@2.80
Rice	2.30	2.30@2.35	2.00@2.30	2.00@2.30
Barley	1.80	1.75@1.80	1.70	1.45@1.70

PHILADELPHIA

Auspicious opening of anthracite trade for current year. Domestic trade good, but steam sizes falling off. No new developments in the bituminous trade. Demand and prices unchanged.

Anthracite—The first of April witnessed the inception of the anthracite trade for the season of 1914 and 1915. Large numbers of orders are being received, and it is felt that there will be no difficulty in taking care of the production for the next few months. While the call is mostly for egg and stove, considerable chestnut is also being moved, and it cannot be said that there is any size that will not be in active demand throughout the month.

Quite a fleet of barges left this port late last week, and during the current week, bound for the New England coast. Most of this coal will go to Boston and vicinity, where it is stated that the dealers are well cleaned out of all sizes. The far Eastern territory, at ports still closed by ice, a fertile field is anticipated as soon as navigation is open; it is understood that the dealers at these points are practically without any supplies, being compeled to eke out what stocks they have with carload lots from the open ports.

The bottom seems to have dropped out of the market for the small sizes. Mild weather is undoubtedly a factor that has much to do with this, coupled with the fact that the mines are operating unrestricted, throwing additional tonnages of the small sizes on the market. Pea coal is selling anywhere from 15 to 25c. off circular by the individual operators, but the large companies do not seem disposed to meet this figure.

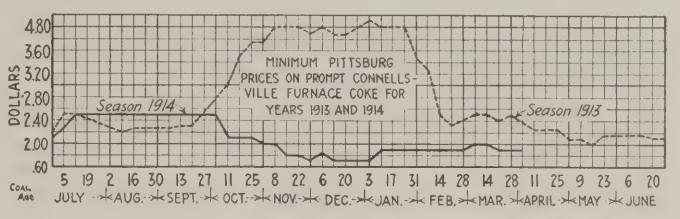
Bituminous—Prices and demand show no material change from last week, with low-grade coals bringing 90c. to $1 at the mines, and the better varieties $1.25 to $1.35. It is evident that the possible trouble in the mining regions has had no appreciable effect on the consumers as yet, and a protracted suspension is apparently not anticipated.

BALTIMORE

Steam coals in better demand in the spot market, largely on sample orders. Slack demand slowing up. Prices steady in the face of threatened labor trouble in the bituminous districts. Contracts engage attention.

The spot market for steam coals shows added strength in demand. In the call for Pennsylvania fuels there are few sales below $1.05 even on the lowest grades. The high-water mark for best fuels is now around $1.35 to $1.40, which is better than for some time past. West Virginia steam coals, in the face of the comparatively poor demand generally, remained quite firm around 95c. to $1.05. The gas product is the weakest feature still and sales were recorded around 85c. Slack demand has slumped again and sales at from 70 to 80c. are noted. That the threat of a strike or suspension in the union fields is not agitating the trade as in some former years is shown by the fact that the price list is quite steady.

Contracting still continues to draw the attention of the trade. There was considerable of purchasing in small lots, apparently for testing purposes. A feature this year is the number of changes being made by consumers in the class of fuels used. This is particularly true of the strictly local situation, this city having been a heavy consumer of a specialized coal. The rapid exhaustion of certain big veins and the rise in price has caused a number of users to try other fuels. This has created much interest to the trade.



Car supply is still worrying the trade. In many instances there are reports of long delays of coal loaded and badly needed for sample purposes on contracts.

CENTRAL STATES

PITTSBURGH, PENN.

Signing of the agreement in the Pittsburgh District will necessitate heavily curtailed operations pending opening of Lake shipping. Coke very dull in sympathy with iron and steel.

Bituminous—There is hardly any coal market as the whole situation has been upset by the reaching of an agreement. The mines of the Pittsburgh district have been operating fairly full, but some of them have maintained operation only by sacrificing prices, and while the regular quotation on mine-run is $1.30 there have been sales down to $1.10. Such cutting is not the result of competitive conditions within the district, but is largely forced by the competition of other districts which have somewhat similar freight rates to various distributing centers. Pittsburgh district sellers insist that they know of much coal being sold from other districts netting $1 a ton or less at mines. The regular circular prices, which are largely nominal, are as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Prospects for at least the early part of the Lake shipping season are poor. It is well known that there are large stocks in the Northwest. The ore market has not opened, there being no inquiry for ore and no prices have been fixed for the season, although frequently prices are named before Jan. 1. The ore movement prior to July 1 promises to be light, and coal movement, which is normally a return haul for ore, must be light also.

Connellsville Coke—The coke market is quiet, reflecting the dullness in the iron and steel trade. A few consumers who were expected to cover for April or second-quarter by this time are holding off in consequence of iron trade conditions. Operators are no longer making a serious effort to secure more than $2 for furnace coke for April or second-quarter, but are altogether indisposed to cut prices. We quote: Prompt furnace, $1.90@2; contract furnace, $2; prompt foundry, $2.40@2.60; contract foundry, $2.40@2.60 per ton at mine.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ending Mar. 21 at 364,080 tons, an increase of 10,675 tons, and shipments at 369,530 tons, a decrease of 7515 tons. Shipments appear to have exceeded production by 5450 tons, against an excess the preceding week of 23,640 tons.

BUFFALO

All branches of coal trade dull except soft slack. Anthracite will pick up early this month, orders being quite liberal. Labor uncertainty continues.

Bituminous—A ready market obtains for slack at a high price. As a result, the buyer is insisting on a supply of this grade, whether on contract or single order while the seller is trying to substitute something else. The result is that most companies are turning down orders in all directions and seeing their mine-run and sizes going begging. There is practically no consumer who really needs any coal except for special use. There has been quite an amount of coal here on track unsold lately which jobbers have been quick to take advantage of.

It will be sometime, whatever happens, before there is anything like a brisk trade again. The consumer as a rule has more coal than he knows what to do with and often will not consider more at any price. There is a claim that even the consumption is running down, especially on account of the failure of iron to pick up. Contracts are well kept up as a rule and there are a good many new ones making, though hardly at prices as high as those of a year ago.

Bituminous remains at $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.25 for slack, with the latter about the only one in demand. Allegheny Valley coal is about 25c. lower, except slack, which sells on a par with Pittsburgh.

Coke—The coke trade continues unchanged, though some ovens are asking an advance of 5c. It will take another week to find whether the higher price holds. General quotations remain on the basis of $4.50 for 72-hr. Connellsville foundry.

Anthracite—There is a good demand for April delivery, with some dealers asking for a car or more on the first of the month, showing that the season has proved colder than they reckoned on and they are in urgent need of more coal, especially of sizes smaller than egg. There is no surplus here yet, but some is expected soon. The warm weather has hastened the apparent time of lake opening, but beyond the 17 cargoes already loaded it is not expected that anything will be done in the lake trade till the season is open.

TORONTO, CAN.

Stocks large and some demurrage coal reported but trade moderately steady in anticipation of possible labor trouble.

Trade has been steady for some weeks although with a falling off latterly in the demand for domestic coal, owing to the setting in of milder weather. The yards are well stocked especially with bituminous, some dealers laying in extra supplies in anticipation of possible labor troubles at the mines. Owing to stocks being in excess of present market requirements there are some 30 cars now held in demurrage. Prices show little change but there is some disposition to shade in bituminous. Quotations stand as follows: Retail anthracite egg, stove and nut, $8.25; pea, $6.75. Bituminous, steam, $5.25; screenings, $4.35; domestic lump, $6; cannel, $7.50. Wholesale f.o.b. cars, three-quarter lump, $3.75@3.85; screenings, $2.90@3.

TOLEDO

Market dullest in the recollection of the oldest operators and dealers. Few contracts. Large quantities of track coal on hand.

The consensus of opinion among the local trade is that Ohio will yet see a strike. In contrast to conditions in the adjoining states, Ohio is confronted with the new mine-run law and operators see no hope of an immediate settlement. This sentiment, however, has had no effect on the market, as buying was never so completely at a standstill as it is now. Contracts for coal are few and far between.

There are great quantities of track coal in Toledo and even the smaller markets in this vicinity report the same condition. One of the roads entering here reported the arrival of 82 cars with no possible market. Prices are so inconsistent that the market is not quotable. Everything is in a waiting condition.

COLUMBUS

Ohio trade in a state of confusion owing to the uncertainty of the future. Some increased demand for stocking purposes and there is apparently sufficient fuel for 60 days. Prices well maintained.

The coal trade is still upset because of the failure of the miners and operators to agree upon a wage scale at the Chicago conference. Uncertainty as to what will take place in the future has caused great conservatism along all lines and "watchful waiting" has become the motto. There was some increase in the demand from steam users during the week but this was not sufficient to cause any great change in market conditions.

Mines in Ohio have been operated close to their full capacity especially in the Pomeroy Bend and eastern Ohio fields. In the Hocking Valley the output is estimated at about 80 per cent of normal and it is still lower in the strictly domestic fields. Large steam users who have not stocked up are relying on their ability to secure West Virginia tonnage in sufficient quantities to keep their plants going. But there is a lot of coal being stored at every point.

The outlook for the lake trade is not bright and that fact is having its effect on the wage negotiations. There is a considerable tonnage on the docks of the upper lake ports and it is doubtful if there will be much lake movement earlier than June 1 even if the wage agreement is signed up. Companies controling their own docks may ship before that date in limited quantities.

The domestic trade is fast waning. Dealers have sufficient stocks to carry them up to the stocking season and they are loath to increase supplies at this time. There is still a small demand for the fancy grades for domestic purposes.

One of the features of the trade is the fact that consumers generally refused to be stampeded over the danger of a prolonged strike. They believe that the trouble will be settled in time for them to make their yearly contracts. Very few contracts are being made at this time although some are being renewed on the same basis as a year ago.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.45@1.35	.....	$1.50@1.40	$1.40@1.35
¾ inch	1.30@1.25	$1.20@1.15	1.35@1.30	1.30@1.25
Nut	1.25@1.20	.....	1.30@1.25	1.25@1.20
Mine-run	1.15@1.10	1.10@1.05	1.15@1.10	1.15@1.10
Nut, pea and slack	0.85@0.80	.....	0.90@0.85	0.75@0.70
Coarse slack	0.75@0.70	1.00@0.95	0.80@0.75	0.65@0.60

DETROIT

Market dull and flat despite the uncertainties in the labor situation. Heavy stocks carried over at the upper lake ports. Anthracite opening up briskly.

Bituminous—The local market still continues weak with slack coal the most active. The uncertainty in labor circles is having an important bearing upon the situation; particularly is this noticeable in the Ohio field where the outlook is more acute. But aside from these uncertainties the market is dull and flat with considerable coal still on track. Heavy stocks are reported at the upper lake ports so that much coal will be diverted from this trade to the detriment of the general business.

Anthracite—The activity which marked the winding up of the coal year in anthracite, served to clean up supplies, and the spring business is opening up briskly. The dealers' bins have been practically cleaned up, and with the maximum discount of the year in effect this month, strenuous efforts will be made to accumulate as large supply as possible at the April figures.

Coke—With a number of the local foundaries closed down indefinitely, the coke market has suffered a severe recession. There have been some shipments refused, with the result that coke is now standing on track accumulating demurrage. Prices are consequently depressed, Connellsville foundry being quoted at $3, Semet Solvay, $3.25, and gas house, $2.75, all f.o.b. ovens.

HAMPTON ROADS

Movement from Hampton Roads improving. Week's shipping fairly heavy with some increase in demand both coastwise and foreign.

Dumpings for the week have been good. The government has taken considerable coal which has been on hand waiting for colliers and this with a fair movement both foreign and coastwise has cut the accumulation in the railroad yards to about normal. In addition to cargo vessels in port during the week there has been a fair number of bunker ships calling here. Several shipments of New River and Pocahontas have moved to the Southern ports and there has also been one or two consignments of high volatile moving South. In addition to coastwise business there has been some large shipments to the following foreign ports: Brindisi, Valparaizo, Canal Zone, Kingston, Havana ,Montevideo, Coronel and Port Spain.

Outside of the coastwise business the inidcations are that the Italian market will take the largest amount of coal moving from Hampton Roads during the current month and while nothing positive can be said at this time it is believed that heavy shipments will also be made to Italy next month While suppliers in general during March have complained of poor movement, railroad figures to date indicate that dumpings for March will run considerably heavier than for either January or February.

LOUISVILLE

Mild weather here has reduced the domestic demand materially, and operators find it difficult to place coal. No stocking movement has begun, and the market is generally quiet.

In spite of the strike talk, retailers in this section have shown no inclination to take advantage of the low prices prevailing to lay in spring and summer stocks and at the same time protect themselves against a shortage later in the season. Moderating weather, with general high temperatures, has resulted in a light domestic demand, and most of the retailers, in consequence, are out of the market, although none of them have much in the way of supplies.

Operators in Kentucky are rather hoping for a strike lasting for 30 to 60 days, in order to reap the benefit of the strengthening effect which it would have on the market. There is no prospect of labor trouble in eastern Kentucky, and in the event of strikes elsewhere, that section would be in a fine position to benefit therefrom.

The steam market in Louisville is fairly strong, largely in consequence of the light production of screenings, rather than because of an active demand. Free offerings of low-grade screenings occasionally give the impression of large supplies, but it does not seem that this is justified. Prices for the better grades are fairly steady around 80 and 85c., with the second grades from 15 to 25c. lower. First-class block hangs at $1.50, with a slow demand.

SOUTHERN AND MIDDLE-WESTERN

NEW ORLEANS

Passing of late cold wave ends domestic season in New Orleans. Further price concessions not expected. Harbor demand light.

Steadied up by the unusual demand for domestic grades during the late cold spell, prices did not reach as low a level as predicted. Further concessions are considered unlikely and in fact the tendency is toward strength as present prices were reached before the heavy consumption of the season-end. As there is no further probability of cold weather here, domestic demand has flattened out entirely. Yards are being cleaned up for new stock.

To add to the general inactivity, shipping has been light for the past week and there has been little demand from the waterfront. No further contracts will be made until the discount season opens. The early opening of the Panama Canal promises to make changes which will affect the demand here. The fact that this will become the starting point of new steamship routes will be an important factor in the amount of coal taken at this port. At present many of the ships leaving here take only as much coal as is necessary to get them to a supply of Pocahontas.

INDIANAPOLIS

Mines active as the end of the wage-contract period approaches. The buying mainly for storage by the large steam users and factories. Uncertainty about suspension interfered somewhat with making of contracts next year.

As Apr. 1 approached and no indication that the operators and miners in the central competitive field would reach a wage agreement, there was a little more coal buying by the big consumers, the railroads and public utilities and this kept the mines busy. The weather has been milder, cutting down the demand for domestic grades, and most consumers think they have bought their last coal for this season. The factory demand has been making gains, probably due mostly to stocking up, to tide over any suspension of work at the mines. There has been little reason for shading of prices, though some of this is reported.

There is difference of opinion among operators as to whether the storage has been as large as in former wage-agreement years. Some mines have not been able to keep up with orders while others could have taken on more; the latter are mostly of the opinion that the amount of storing has not been up to the average. The belief is general that there will be no suspension, whether or not an agreement is reached by Apr. 1, and this has curtailed the storage buying to some extent. It is said there has been less accumulating of coal at the mines or elsewhere, but there is considerable surplus carried in cars.

The retail trade in this city is closing the winter season at the same level of prices as at the beginning.

CHICAGO

Despite the suspension no anxiety is shown among consumers. A little more than normal buying aided in taking up coal that was approaching demurrage. No material increase in prices.

Retailers of domestic coal are in about the same position as steam-coal dealers, being well enough stocked with the ordinary grades to counteract the effects of a short mine suspension. Normal conditions prevail in the anthracite market which is not effected by the situation in bituminous. With the weather warm and consumption light the buying has been slow and dealers are awaiting the Apr. 1 discount.

Contracting has been the principal feature of the smokeless-coal market, the all-rail business being heavier than last year, with about two-thirds of the prospective business already disposed of. Considerable spot coal was marketed in Chicago during the week. Contract shipments have been about completed by the producers. There seems to be no tendency to speculate on the prospects of a mine suspension by larger shipments to Chicago.

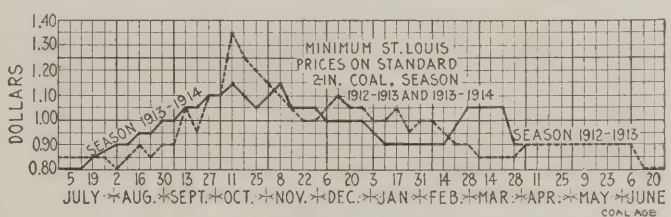
Franklin County operators filled all of their orders during the week and are in a good position to take advantage of a flurry in the event of a strike scare. Their coal is being marketed at $1.50 as the high price and running down to $1.20. The Carterville trade is in a similar position, with a good deal of coal being sold in the spot market. The highest price for domestic sizes is $1.50 with a shading down to $1.15. The steam trade was the feature of the Springfield market with a fair demand for mine-run and steam lump and an improving market for screenings. The Indiana operators are keeping to their own districts and not attempting to ship to Chicago, which is already overcrowded. Prices are being readjusted in the coke market, the byproduct coming in for a reduction of 50c. with the arrival of the discount period.

Prevailing prices at Chicago are:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.07@2.17	$2.40@2.55	$2.12@2.27	
Steam lump	1.97		1.97	
Egg		2.40@2.55		$4.70
Mine-run	1.87	2.20@2.25	1.87	3.30
Screenings	1.67@1.77	1.90@2.05	1.67@1.77	

Coke—Connellsville and Wise County, $5 and $5.25; by-product, egg, stove and nut, $4.50; gas house, $4.25.

ST. LOUIS



Month opens with trade dull and stagnant. Prices low with little coal moving. Anthracite the only active branch.

The last week in the month saw practically no coal moving. The railroads had stored some coal previously, and some steam plants also but the tonnage has been insignificant as compared with previous years. Even screenings, which under normal conditions, are in good demand, were heavy. The opinion prevails in some quarters that there is still a chance for the operators and miners to get together in Illinois. Prices remain the same as for several weeks, and in many instances some coals were lower; regular summer conditions prevailed with demurrage coal on the east side.

The only life in the St. Louis market was occasioned by the future sales of anthracite, for April, May and June, which seem to be good. There is some smokeless being sold, but no coke. Up until the last few days the retail demand for coal was fair. The retailers during the past season had nothing to complain about, business being about normal and prices away below what was expected.

The market at the closing of the month was:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump				$0.90 @ 1.00	$1.15
3-in. lump			$1.35		
6-in. lump	$1.35 @ 1.50		1.50	1.15 @ 1.25	1.35
Lump and egg	1.85 @ 2.15	2.25			1.15
No. 1 nut	1.30 @ 1.45				
Screenings	0.85 @ 0.90			0.65 @ 0.70	0.75 @ 0.80
Mine-run	1.10 @ 1.20			0.80 @ 0.85	
No. 1 washed nut	1.50 @ 1.60	2.25	1.50		
No. 2 washed nut	1.25 @ 1.35		1.25		
No. 3 washed nut	1.25 @ 1.30				
No. 4 washed nut	1.25 @ 1.30				
No. 5 washed nut	0.80 @ 0.85				

KANSAS CITY

Mines working at about summer schedule and business unsatisfactory.

Conditions in the Kansas and Missouri field are unsatisfactory at present, with little prospect for any improvement in demand. A cold wave predicted during the past week failed to make its appearance. This development means probably that no more cold weather is likely in this section. Operators are down practically to a summer basis, working about half time in most cases. Domestic demand is light, and business confined mostly to contracts.

PORTLAND, ORE.

Winter season practically over and coal dealers find business rather quiet. Short spell of cold weather.

Winter is over here, except for an occasional cool spell, but the temperature did not fall sufficiently low to cause any great rush for supplies. Business is quiet, so coal dealers report, and as for the future the demand will come practically altogether from industrial concerns, or regular consumers. Issaquah coal is now offered here to the retail trade at $7.50 per ton delivered to any place within the main part of the city. This coal comes from the new Issaquah mine in Washington, in the vicinity of Seattle, and will probably mean quite a factor in the local retail trade.

The amount of coal imported here the past winter from Australia did not exceed a couple of thousand tons and hence this fuel did not figure much in this market.

PRODUCTION AND TRANSPORTATION STATISTICS

BITUMINOUS COAL MOVEMENT

The following is a summary of the movement of coal and coke over 13 principal railroads during January of the last four years:

Anthracite	1911	1912	1913	1914
Baltimore & Ohio[1]	105,415	175,185	195,667	137,270
Chesapeake & Ohio[1]	2,010	3,155	378	1,043

[1] Includes coal from connecting lines.
[2] Includes company's coal.
[3] Does not include company's coal hauled free.

Note:—The Southern Railway hauled 345,899 short tons of bituminous coal during December, 1913, and 4,215,614 short tons during the 12 months.

PENNSYLVANIA RAILROAD

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for February and the two months of 1913 and 1914, in short tons:

	February		Two Months	
	1914	1913	1914	1913
Anthracite	705,020	988,036	1,620,047	2,002,295
Bituminous	3,556,665	3,857,304	7,674,179	8,067,500
Coke	819,486	1,220,360	1,672,898	2,508,874
Total	6,081,171	6,065,700	10,967,124	12,578,669

U. S. STEEL'S COAL PRODUCTION

The United States Steel Corporation during 1913 mined 6,705,381 tons of coal as against 5,905,153 tons in 1912; this is exclusive of that used in making coke. Coke manufactured in beehive ovens in 1913 totaled 11,062,138 tons as compared with 11,554,840 tons in 1912. Production of byproduct coke in 1913 amounted to 5,601,342 tons as compared with 5,164,547 tons, making the gross production of both beehive and byproduct coke in 1913 at 16,663,480 tons as compared with 16,719,387 tons in 1912.

BALTIMORE & OHIO

The following is statement of coal and coke tonnage moved over this system and affiliated lines during February and the first two months of this year and last year:

	February		Two Months	
	1914	1913	1914	1913
Coal	2,385,343	2,550,417	5,303,077	5,553,821
Coke	265,380	371,355	540,335	810,531
Total	2,650,623	2,921,772	5,843,412	6,364,352

FOREIGN MARKETS

FOREIGN TRADE OPPORTUNITIES

The United States Consular Service reports opportunities in foreign coal markets as follows; complete details regarding different items can be obtained on application to the Bureau of Foreign and Domestic Commerce, Washington, D. C., by giving numbers:

An American consul reports that firms in his district have been using wood as fuel, but the price is rising rapidly and there are prospects for the sale of coal. Copy of the complete report, giving further details and the names of the firms to be addressed regarding this matter, can be obtained from the Bureau of Foreign and Domestic Commerce.—**No. 12,750.**

BELGIUM

Belgium imports and exports for the first two months of this year and last year were as follows:

	Imports		Exports	
	1914	1913	1914	1913
Coal	1,454,386	1,462,908	867,671	815,120
Coke	163,851	222,362	213,176	173,123
Briquettes	80,127	75,694	121,053	81,466

FRANCE

French imports and exports for January of this year and last year were as follows:

	Imports		Exports	
	1914 Tons	1913 Tons	1914 Tons	1913 Tons
Coal	1,521,551	1,351,300	70,677	95,287
Coke	202,274	286,400	11,076	20,842
Briquettes	105,021	78,800	12,750	9,311

British Exports—The following is a comparative statement of British exports for February and the two months of the last three years, in long tons:

	February		2 Months		
	1913	1914	1912	1913	1914
Anthracite	187,057	250,217	447,199	485,365	520,088
Steam	4,046,314	4,186,768	7,941,579	8,464,307	8,418,149
Gas	875,335	883,070	1,730,471	1,776,699	1,768,783
Household	323,350	280,174	264,903	293,587	257,362
Other sorts	323,350	280,174	552,007	620,277	526,265
Total	5,569,917	5,725,877	10,936,159	11,640,235	11,520,647
Coke	98,755	94,595	222,040	205,850	218,851
Manufactured fuel	154,253	154,136	310,183	350,992	324,081
Grand total	5,822,925	5,974,608	11,468,382	12,197,077	12,063,579
Bunker coal	1,539,410	1,615,132		3,297,089	3,346,144

Havana, Cuba—Practically all coal used by Cuba is furnished by the United States, in contrast to other Latin American republics that get the bulk of their supply in England or Australia, depending on the side of the continent on which they are located. Cuba used 123,897 tons of anthracite last year and 2,076,375 tons of bituminous coal. Of the 11,645 tons of coke consumed, the greater portion was furnished by Great Britain.

COAL SECURITIES

Mine No. 48 of the Central Coal and Coke Co., Near Girard, Kansas, and Some Men Who Work in It.

Barsteel Heavy Haulage Locomotive

4 Features of Baldwin-Westinghouse Barsteel Electric Mine Locomotives That Assure Maximum Tonnage with Least Expense

The Cast Steel Bar Frame which gives great strength with least weight; permits easy access to, and excellent ventilation for the motors.

The Vauclain Removable Gib which greatly facilitates the removal of journal boxes and permits inspection or replacement of all wearing parts with a small cost of time and labor.

The Oil and Waste Lubricating System for the motors, with specially designed bearings for long life in service, which has been adopted as a standard after years of investigation.

The Commutating-Pole Motors which insure sparkless commutation at all loads. As a result, the commutator and brushes are long lived and require little attention, brush renewals are seldom required, and carbon and copper dust inside the motor is practically eliminated.

These features are but few of many which have been incorporated in Baldwin-Westinghouse **Barsteel** Electric mine locomotives in order to give the user the greatest possible service. You can obtain them only when you specify Baldwin-Westinghouse.

Address either company for full information.

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED

*Illustrated Article

FOREWORD: *Page* 597

Which? Poem by Berton Braley.

IDEAS AND SUGGESTIONS: *Pages* 598-599

*Small Timber-Framing Plant—A Simple Philosophy of Life—*Blacksmith Stand.

*THE I. & S. C. M. CO.'S PLANT, AT ISSAQUAH, WASH.: *Pages* 600-603

Description of an unusually effective installation for handling and treating the low-grade Pacific Coast fuels. The coal is carefully sized and both hand-picked and washed. L. S. Richards. COAL AGE, Vol. 5.

THE AIR FACTOR IN MINE EXPLOSIONS: *Pages* 603-604

Quotes the statements of the British Explosion in Mines Committee, contained in their recent report, to show the necessity of determining those factors affecting the rate of combustion of coal dust in suspension in mine air, since it is the rate of combustion that determines explosion of the dust. John Verner. COAL AGE, Vol. 5.

*LONGWALL MINING IN KANSAS: *Pages* 605-606

The lower seam in the mineral field south of Pittsburgh has been practically exhausted. The operators are preparing to mine the upper seam by the longwall method. The writer describes some of the conditions encountered and gives, in part, the scale agreed on in this connection. Barry Scobee. COAL AGE, Vol. 5.

DEVELOPMENT IN COAL-LOADING DOCKS: *Page* 606

*A TRIANGULATION SURVEY OF THE FAIRMONT REGION: *Pages* 607-610

A description of one of the largest surveying projects ever undertaken in the coal industry. It involved precise control of a territory 90 lineal miles in length and comprised an area of 250 square miles. A description of both field and office methods employed. A. W. Hesse. COAL AGE, Vol. 5.

*WIRE ROPEWAYS FOR COAL TRANSPORT: *Pages* 611-612

The wire ropeway often is found more adaptable to mining operations than the railway. It is not usually subject to the formation and configuration of the land, and it is both simple of construction and inexpensive of operation. COAL AGE, Vol. 5.

Advertising Is Specialized For You

The Weekly Ad-Talk Page

Advertising puts before you the worthwhile commercial news.

You should therefore be interested in advertising of all kinds and of all kinds of propositions.

But when it comes to your particular business—you are interested only in things which will help you secure better results in your field.

And therein lies the especial value of the selling section of your technical paper—it puts before you the merits of only such propositions as apply directly to your field.

You do not expect fiction or general news in the reading pages—you subscribe for the technical paper solely for the purpose of improving yourself, of gaining knowledge that will mean greater success and profit—and the reading pages are therefore restricted to only that kind of article that will help you in your line of work.

The Selling Section is governed by the same policy.

When you want this information or that information, when you want to find the arguments presented by the different manufacturers, you do not want to see piano announcements or automobile advertisments.

And so in the selling section of COAL AGE you will find the business news of only such apparatus and articles as can be used to good advantage in the coal mining field.

The Selling Section, in fact, is part of your business; it is a business tool which can be used with telling effect.

Sometimes you may be puzzled; your present methods of accomplishing certain results may not be entirely satisfactory to you; the equipment may be wrong—look to the Selling Section of COAL AGE.

It will give you the necessary suggestions on how to secure better results than you are getting, how to solve your puzzling equipment problem; and not only that, but it will tell you where to buy the material necessary to accomplish the desired results.

Remember these three things:

(1) Only good goods can be continuously advertised.

(2) Only reliable products lend themselves to the reason-why kind of copy that is required nowadays to make advertising successful.

(3) Only advertisements of products or machinery which can be used in your business find entrance into the Selling Section of COAL AGE.

COAL AGE

Vol. 5 NEW YORK, APRIL 11, 1914 No. 15

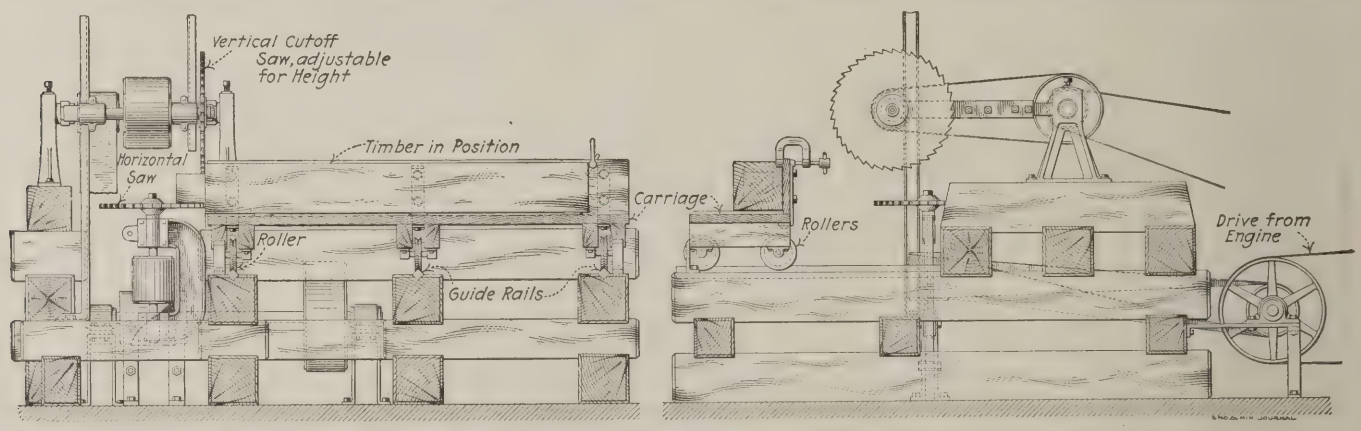
Which?

By Berton Braley

Written expressly for Coal Age.

Shall it be Peace or War? Reason—or Force?
Which is the course?
Shall doubt, dislike,
Avarice, blindness—grow to Wrath and Strife?
Shall weeks and months be rife
With all the bitter conflict of a strike,
Or shall the Masters and the Men, grown wise,
Have done with prejudice and craft and lies,
And seek the way of patience and of Peace,
That Labor wars may cease?

We are so weary of the constant fight,
So sick of labor struggles in the land,
So burdened with the wastage and the blight
Wrought by the minds that WILL NOT understand,
That we cry out to Capital, "Be sane,
Not grim, relentless, with a heart of greed,
But open-minded, willing to concede,
To compromise—and save a world of pain."
And so we pray to Labor, none the less,
"Let us be through with selfish stubbornness,
Which means so much of hardship and distress,
Let us have peace—the peace we've hungered for,
We are so tired of War!"



What is the answer, brethern; shall the mines
Lie idle and the country lack for coal
While want and destitution stand for signs
Of sternest struggle—or shall men control
Their battle spirit and with mutual trust,
Seek only to be just?
Shall it be Peace or War?

Ideas and Suggestions

Small Timber-Framing Plant

By Frank M. Leland*

About two years ago, we found ourselves in the position of a great many medium-sized mines. We needed a large quantity of square sets and had been doing the same as most mines of this size, viz., cutting trees, hauling them in full length and dumping them in our timber yard, paying for them by the linear foot. We kept five or six timber framers working under a shed and they would go out and select timbers to suit, saw them off with a two-man crosscut saw, roll them under the shed, hew one side flat with a broadax and then get out a little gage, mark off the ends and proceed in the usual manner to saw them part way in and frame the ends as required.

The Home-Made Framer, Showing Bed, Carriage and Jaws

By the time they had ground up their tools and filed their saws, filled their pipes and lighted them, gone into the boiler room in winter to warm their fingers and performed a few other functions that every mine manager is familiar with, these hand-framed timbers had cost us a great deal of money. Up to two years ago, we had not required so many and we did not notice the expense so much, but when I found that we required a great many timbers, I began looking around for machinery.

The first thing we considered was a regular timber framing machine, but found on getting prices that one would cost from $2500 to $3000, weigh about 9000 lb., and require a 50-hp. engine and boiler to drive it and then it would only cut the tenons on the ends.

I figured the cost of a building and all the machinery erected, and found it would approximate about $7000, which, for the work we had to do, was too large an investment. So I thought I would buy a slabber and a swinging cut-off saw and rolling the timbers to the cut-off saw, cut them in lengths to suit, and slab them on one side in order to get a starter for hand work. I purchased the slabber, complete with saw and the swinging cut-off saw for $420. We erected it at the smelting plant and cut off and slabbed a lot of timbers, but it proved a disappointment; the timber framers rather resented our taking their work away from them and in the usual well known manner, they made the finished timbers cost about as much as before.

I then began to figure how I could take the machinery and frame the timbers; the drawing illustrates how we did it. I built a frame of 8x8-in. timbers and laid the cut-off saw frame horizontal instead of vertical. I rustled up an old vertical 7x10-in. engine and connected is as shown, using channel irons with slotted holes so that the saw frame would move up and down, cutting any depth desired, or could be lowered clear down and used to square the timbers.

I then rigged up another saw running horizontally. This does not cut at the same time as the vertical saw, hence only power enough is required to drive one saw at a time. The design is not beautiful, it was made without drawings, and figured out as we went along. The guide rails under the table are made from 1½-in. square iron set edgeways; the rollers we turned out of some old matte pans; the pulleys and shafting, we picked up around the place. The machine is strictly homemade, but it is good and strong and it runs perfectly.

Method of Operation

The posts are first sawed on the slabber, they are next squared on the ends by running through the machine, say one hundred of them, the saw is then raised up so as to cut just 2 in. deep. The horizontal saw remains stationary, the stick is shoved through and the cut made on top, the carriage is then shoved on the horizontal saw and a slice taken out of the bottom; it is then pulled back and rolled over one quarter and the operation repeated; it requires four cuts to finish the end.

I have repeatedly timed it and find that it averages 3½ min. to frame both ends of an 8x8-in. post. The slabbing saw takes logs up to 8 ft. in length and when we received it, we made a set of dogs and some perforated plates to hold pins, and bought an inserted tooth saw to replace the thin saw which came with it; it is surpris-

*Mr. Leland whote this article when president of the Empire Copper Co., Mackay, Idaho. He is now general manager of the Balaklala Copper Co., Coram, Calif.

ing how fast we can rattle out the timbers. When we started, all we hoped to make was square-set timbers, but we found that by getting logs 8 ft. long, we could make our lumber for just about one-half its cost when purchased from the saw mills. We found also that we could saw 2x4-in. stuff for ladders, 4x6-in. for flooring for the square sets, in fact, almost anything up to 8 ft. long, and we find that 2x12-in. by 8-ft. lumber is just as good for chutes, etc., as is 16-ft.

We rigged a little wedge saw to use up the scraps and find that our wedges cost us 3/8c., whereas, made by hand, they cost us 6c. We also make ladder rounds 2½ in. square by 16 in. long, ripping them on the small mill. We find many advantages which we did not think of at the start. The principal one is the fact that from every timber we get four slabs, two of which are generally good for lagging and in almost every case we get enough lagging from the timber to pay for the timber itself, since we would have to use 2-in. plank, if we did not have this lagging. Furthermore, the boiler being purposely left naked, warms up one end of the shop and for the other we use live steam in coils of pipe; the fuel costs nothing, since we burn the saw dust. This is quite an item, as it ordinarily takes from 300 to 400 lb. of coal daily to keep the shop warm.

Finally, these machine-framed timbers can be erected in the mine at a lower cost for labor than the hand-framed, since they are all true and fit exactly.—*The Engineering and Mining Journal.*

A Simple Philosophy of Life

Written in a scrawly hand on a piece of paper, since grown grimy, the following lines grace the inside of a closet door:

> In the adage good and old,
> We forevermore are told
> That it's better far to give than to receive.
> So the boost that always lends
> Helpful thoughts to troubled friends
> Is that bread cast on the water we retrieve.

The stanza gains significance with additional facts. The closet just mentioned is a fixture in the hoisting-engine room of a large coal-mining operation. Its contents range from cotton waste and brightly polished oil cans to a change of clothing and a dinner pail. The only man having access to the lock is the hoisting engineer, who, for obvious reasons, we will call "Smith"— and thereby hangs the pith of that which follows.

Smith has admitted, modestly to be sure, that he is the propounder of the above verse.

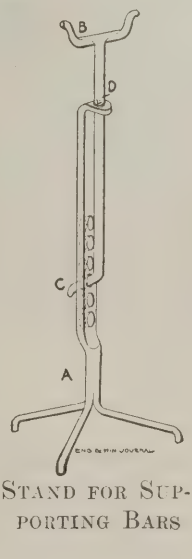
It bears a positive relation to Smith's attitude toward his daily work. He expresses his simple philosophy of life in the language of action. If you watch him operate the hoist, you will note the pleasure on his face as he throws his levers with the precision of a faultless mechanism. His answer to a fellow workman is always of the kind which promotes harmony. He has learned the knack of self-effacement.

A glance at Smith and you can discern a mixture of the milk of human kindness and a thoughtful determination that would guard safely any confidence you might impose in him. Being more or less a child of fancy, he has cultivated the habit of introspection and therefore tries to see himself as others see him.

Smith's daily work includes business flavored with action, a friendly boost or perhaps a josh. And his work has found him out, for his employers recognize him as a leading spirit.

In a word, Smith firmly believes that appearances dominate feelings; to be happy one must *smile.*

If "nothing succeeds like success," how doubly true it is that nothing fails like failure. Most of us take our views of life from the atmosphere in which we live, but all of us are endowed with ambition.



Neither success nor failure are dealt out with a single turn of fortune's wheel. The success we all crave is the result of untiring effort, and the only foundation on which it will thrive is kindness to our fellows.

From an ambitious viewpoint kindness is a paying investment. Don't knock, boost, and your boost will find you out.

In one sense Smith is a gifted man, and though we are not all of his temperament, we can at least apply his remedy for a discouraged spirit. It is equaled by none. Try it—*Smile and be happy.*

Blacksmith Stand

The rest illustrated is of simple design and inexpensive to make; it will be found useful for holding up light work in the machine shop or smithy (*American Machinist,* Jan. 29, 1914). It consists of a standard *A,* which has three feet, and of a rest *B.* The rest is adjusted to the desired height by putting its lower end *C* through one of the holes in *A.* These holes are bored or punched about 1½ in. apart, and should be made at an angle, as shown by the dotted lines, so as to insure a safe hold of the shank when weight is placed upon the rest *B.* The hole in the head of the standard marked *D* through which the shank of the rest slides up and down, must be made large enough to allow for the movement of the shank when the point *C* is being taken out, or being put through any of the holes in the standard *A.*

Stand for Supporting Bars

Owing to the improved methods, seams of coal have been worked in Britain at a depth of 3000 ft., and in one mine in Lancashire, 3700 ft., which means a natural temperature of over 90. The method of ventilation has been improved, and Sir W. E. Garforth believes those who are now studying will perfect in years to come a small fan for each coal face, in order that the miners may obtain an increased velocity of air —utilizing the fan in much the same way we all use fans on a hot summer's day.

A new system of signaling has been instituted at the Windsor colliery, in South Wales. They are endeavoring to abolish all electric signaling, and have devised a scheme of signaling with blast hooters, which have been put on every main-haulage engine on the east side of the colliery. The hooters are attached to a compressed-air column, and this is said to operate successfully. The pulling of a wire which runs along the roadway gives the signal to the engineman. It is said there is absolutely no danger of sparking with the new system.

The I. & S. C. M. Co.'s Plant at Issaquah, Wash.

By L. S. Richards*

SYNOPSIS—Description of an unusually effective installation for handling and treating the low-grade Pacific Coast fuels. The coal is carefully sized and both hand picked and washed. A new method of screening, termed a "flexible hanger shaking screen" was installed; although common to the anthracite fields this is the initial installation of this apparatus on the Pacific Coast.

The Issaquah & Superior Coal Mining Co., of Seattle, have recently completed a plant at Issaquah, Wash., for the preparation of lignite coal which is of especial interest because it is the most modern and complete of its kind on the Pacific Coast. The design of the entire plant was made and the machinery furnished by the Link-Belt Co., of Chicago, and the plant was erected and put in operation under the supervision of their engineers.

General View of Tipple and Washery

Tipple Arrangement

The coal is received from the mine in two-ton cars, being handled from the mouth of the drift in trains of 30 or 40 cars by an electric locomotive over a covered trestle about 700 ft. long. The cars are passed singly by gravity, over a track scale to a power-driven revolving tipple, a car stop being located between the scale and the tipple which enables the operator to regulate the cars going into it.

The revolving tipple consists of a structural-steel framework carrying a pair of rails for receiving the cars. This framework is supported at the ends by cast-steel rings which are carried by a pair of roller shafts on which the tipple revolves. The power for operating is received through one of these shafts, which is constantly revolving. The working of the tipple is controlled by means of a lever system through which the operator lifts the rings slightly out of contact with the driving rollers upon the completion of a revolution. This lever system is so arranged that the tipple is automatically stopped without the slightest jar.

The empty is forced through the tipple by the oncoming car and passes, by gravity, to a kickback which reverses its direction and switches it to the empty track, where it is stopped by a track brake. Here it is picked up by an inclined car haul and elevated to a height sufficient to allow it to pass by gravity back to the mouth of the drift.

Screens and Picking Table

The tipple discharges the coal into a hopper so arranged that the coal is eased down into it with practically no fall. This hopper is provided with a flop gate so that when rock is dumped it can be passed to the rock bin, located directly below it. The coal is fed uniformly from this hopper by a reciprocating feeder to a pair of shaking screens, the upper screen having 4-in. round perforations and the lower 2½ in. These screens separate the coal into 4-in. lump, 2½x4-in. egg, and 2½-in. slack.

The lump and egg coal are separated only for convenience in picking, each passing to an independent picking table, of which there are two. These tables discharge onto one loading boom which delivers the coal to the railroad cars. The tables are of the flat-top apron type and are of ample width so that the coal is spread out thinly, although the apron moves at only 50 ft. per min. The pans form a perfect circle around the head wheel which permits of the discharge chute being set high up to eliminate the fall of the coal at this point without allowing any leakage of the fine coal, since the chute may be set close to the pans.

The loading boom is of the corrugated apron type, which offers a maximum resistance to the sliding of the coal. It is provided with small diameter wheels at the discharge end, thus minimizing the drop of the coal into the car. The raising and lowering of the loading boom is accomplished by a worm-gear winch, power-driven and controlled by a set of bevel friction gears.

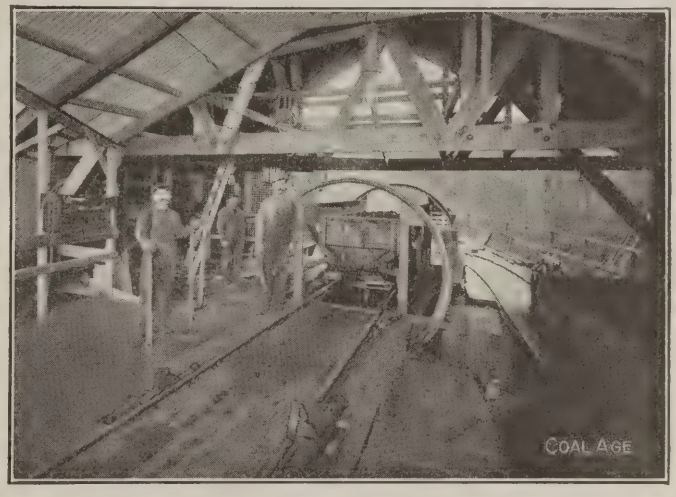
The rock and refuse, which are picked from the lump

*Engineer, with the Link-Belt Co., Chicago, Ill.

Draining and Sizing Screens for Washed Coal

Interior of Washery, Showing Link-Belt Jigs

and egg coal, are passed, by means of chutes, to a double-strand flight conveyor, located below the picking floor which discharges into the rock bin. The pieces of coal which have rock or clay attached to them are passed by the pickers to a single-strand flight conveyor alongside the rock conveyor. This delivers it to a spring relief crusher, which crushes it to 2½ in. and under.



A Flexible Hanger Shaking Screen

The slack coal through 2½ in. from the lower shaking screen passes to a gravity-discharge conveyor which distributes it over a 500-ton raw-coal storage bin. This conveyor is arranged so that the return run passes underneath the bin and the coal is reclaimed by being fed into this run through slide gates, and elevated to a 100-ton raw-coal bin in the washery. The coal and rock from the crusher are also fed into this run of the conveyor and carried to the washery. The slack coal in discharging into the washery bin, passes over a flexible hanger shaking screen with ¾-in. round perforations from which it is delivered to two compartments, one for ¾-in. slack and one for ¾x2½-in. nut, each of 50 tons capacity.

This flexible hanger shaking screen is somewhat of a novelty in this part of the country, although extensively used in the anthracite fields of Pennsylvania. The sides are of 3x6-in. pine timbers and the connecting-rods 3x6-in. ash, rigidly attached to the side timbers. These connecting-rods are dressed down in the middle portion to a section of about 3x3 in. The hangers are 1x6-in. ash boards rigidly attached to the screen and to the supporting timbers. The screen is run at a more rapid rate than the ordinary shaking screen, and this together with the sharp action given by the spring in the hangers and connecting-rods, makes this apparatus most efficient in screening fine coal. It is more effective, and there is less breakage than with a revolving screen.

System of Washing

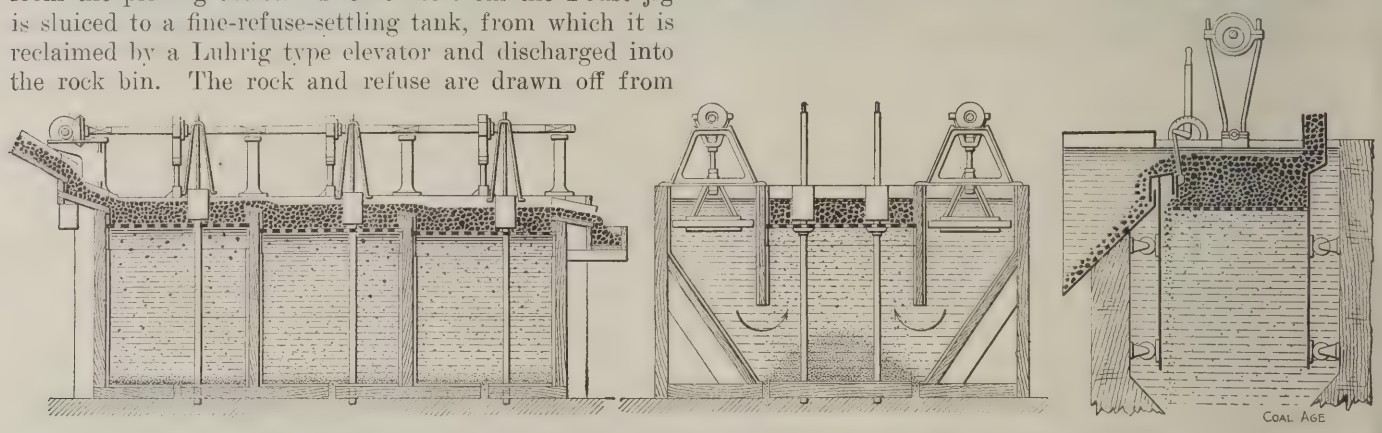
The coal is fed from the bottom of these bins through vertical slide gates to the washing jigs, the slack going to a Link-Belt three-compartment Foust jig, and the nut to a Shannon jig. The washed coal from each of these jigs passes to an independent settling tank and from there into a Luhrig type elevator. The nut coal is delivered

Revolving Tipple and Car Stop

to a shaking screen with ¾-in. round perforations where it is resized and sprayed with fresh water and delivered to a single-strand flight conveyor. This conveyor distributes it to the washed-coal bins. The undersize coal, together with the spray water from this screen is sluiced to the Foust jigs where it is rewashed with the slack coal. The washed slack from the Luhrig elevator discharges onto a pair of shaking screens where it is sprayed with fresh water and graded into pea through ¾ in. and over

Egg- and Lump-Coal Picking Tables

Distributing Conveyors for Washed Fine Coal



¼ in. and buckwheat through ¼ in. and over ⅛ in. The buckwheat is distributed to the bins by means of gates in the shaking screen and the pea coal passes to a single-strand flight conveyor which distributes it to the bins. These washed-coal shaking screens are all of the flexible hanger type, as described above.

The refuse from the Shannon jig passes into a Luhrig type elevator and is discharged into the rock conveyor from the picking tables. The refuse from the Foust jig is sluiced to a fine-refuse-settling tank, from which it is reclaimed by a Luhrig type elevator and discharged into the rock bin. The rock and refuse are drawn off from the rock bin through two undercut gates in the bottom and loaded into a gable-bottom refuse car of two tons capacity. This car is hauled up an inclined trestle by a wire rope operated by a friction drum and by means of a special tripping device it is dumped at any desired point along the trestle.

The washed-coal bins are provided with horizontal slide gates and hinged chutes for delivering coal to the railroad cars. The chutes are so arranged that when not in use they may be drawn up into a horizontal position and clear of the drip from the gates. The overflow water from all the tanks passes to a pump box from which it is drawn by a double-suction centrifugal pump supplying water to the jigs. The fresh water is supplied by a two-stage centrifugal pump from a near-by creek.

Machinery Equipment

The machinery is driven by 220-volt, three-phase, 60-cycle induction motors, there being ten all together throughout the plant. The power is supplied by the Puget Sound Electric Co. from their plant about 15 miles distant; it comes in over high-tension lines, and is

Two Types of Jigs (Foust and Shannon) Used in Washing Coal

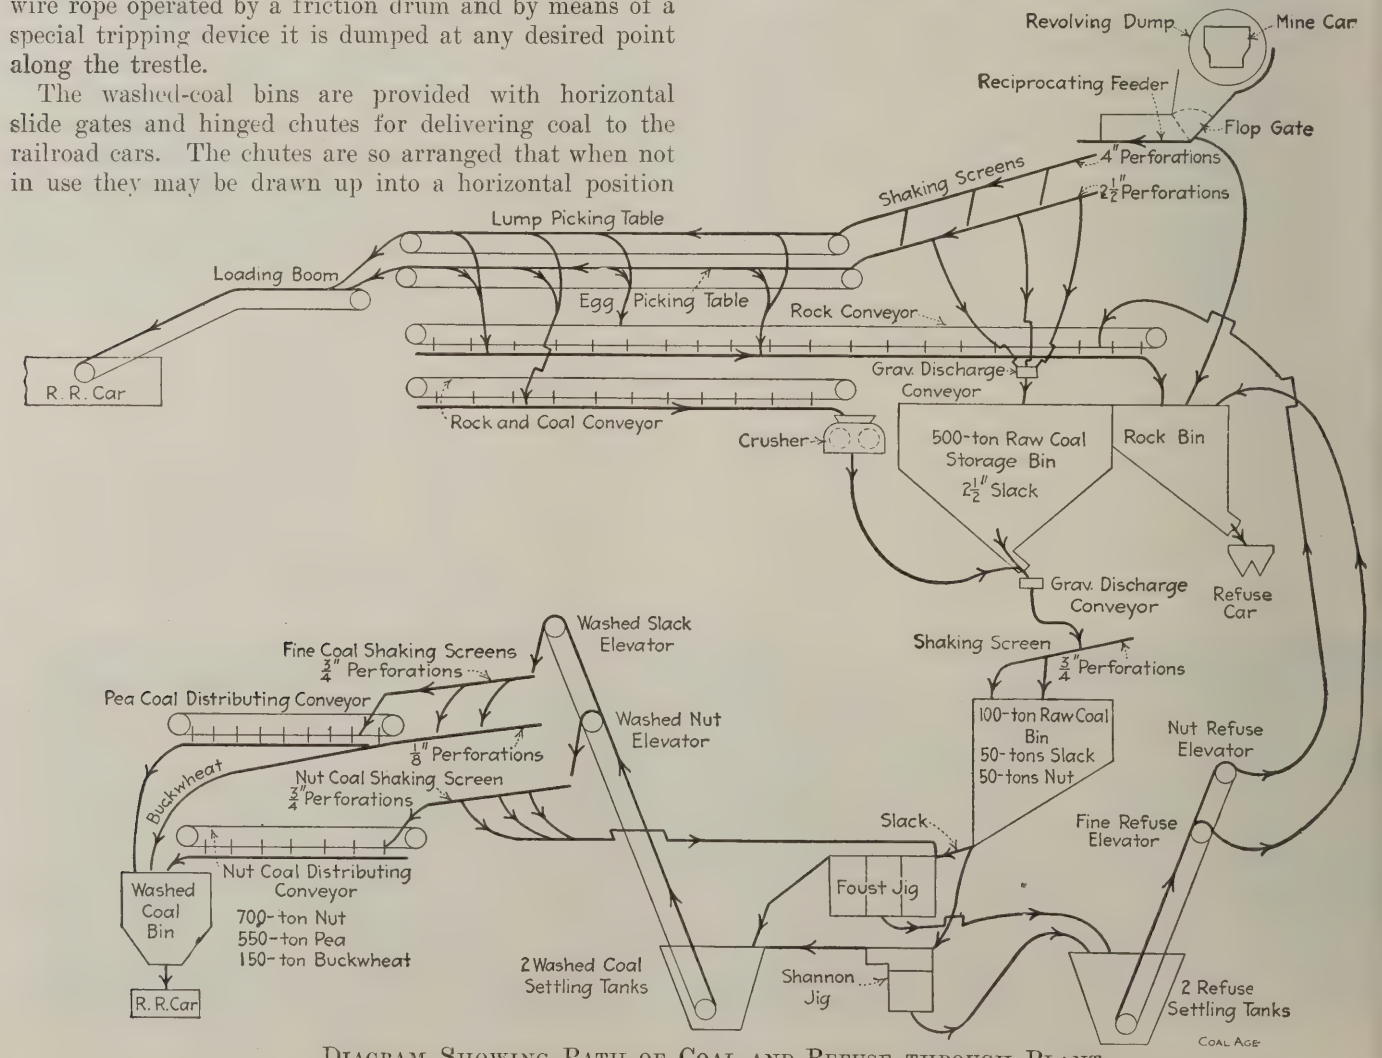


Diagram Showing Path of Coal and Refuse through Plant

transformed at the plant. The machinery supports, tanks, bins and building structure are of No. 1 Washington fir throughout, and the utmost care has been taken in framing to make a thoroughly workmanlike job. The roofing and siding are galvanized corrugated iron.

The coal is loaded out on two tracks, the lump and nut on one, and the pea and buckwheat on the other. There is also an arrangement of conveyors whereby nut can be stored in the pea-coal bins if desired and loaded out on the pea track. The nut-coal storage capacity is 700 tons, the pea coal 550, and the buckwheat 150 tons. The lump coal is loaded direct to the cars as previously explained. The plant will handle cars from the mine at the rate of 200 tons per hour, and the washery will handle the 2½-in. slack at the rate of 90 tons per hour.

This plant has now been in operation about four months and Issaquah has already become famous for the high-grade quality of the prepared coal which it is supplying to the trade. The plant has more than fulfilled the highest expectations of the engineers in charge and promises to revolutionize the coal industry on the Pacific Coast in some respects.

The Air Factor in Mine Explosions

By John Verner*

SYNOPSIS—Quotes the statements of the British Explosions in Mines committee, contained in their recent report, to show the necessity of determining those factors affecting the rate of combustion of coal dust in suspension in mine air, since it is the rate of combustion that determines explosion of the dust. The compression and disturbance of the mine air do not necessarily cause explosion of dust in contact with flame. The counter current a strong factor. Two experiments suggested, to be made in the Experimental Mine, at Bruceton.

The following important statement appears in the fourth report of the British Explosions in Mines committee:

> In the combustion of gaseous mixtures, there is no well defined border line between inflammation and explosion, the two terms being employed merely to indicate differences in the rapidity of combustion. But in the burning of mixtures of coal dust and air, it appears possible, and indeed necessary, to draw a line of distinction between inflammation and explosive combustion.
>
> Briefly, our view is that during an inflammation of coal dust (at all events, that of bituminous coals) the flame is propagated, largely, by the burning of gases distilled from the dust; whereas, during explosive combustion, the portion of each dust particle that aids in propagating the flame is burned as a whole, both the volatile matter and the fixed carbon being consumed.

In view of this statement, it becomes a very important matter to find the factor that determines the *rate* of combustion and to discover the process by which explosive combustion is produced. The position of the British committee, in this respect, is not clearly defined. The report states further:

> When inflammation occurs and the flame proceeds along the gallery, the expansion of the gaseous products of combustion causes a movement of a column of air which is pushed forward in front of the flame. The opposition to this movement may be approximately calculated, for a smooth gallery, since it depends on the inertia of the air to be moved, or the velocity of the air pushed forward and the size of the tube. But in the roadway of a mine this opposition may be enormously increased by the irregularities and obstructions, which cause waves and eddies in the air. A cloud of dust so compressed burns with greater rapidity than in still air. The effect on the advancing flame is thus cumulative.

Compression and Disturbance of Air Do Not Determine Explosion

This would permit the conclusion that the greater the compression and disturbance of the mine air, in the presence of flame that may come in contact with the raised dust, the more probable the occurrence of an explosion. But this does not seem to be the case, judging from the facts. The recent explosion in the Dawson mine, New Mexico, Oct. 22, 1913, was caused by the firing of a single shot. The occurrence of this great disaster, in which some 261 lives were sacrificed, shows that the dust was readily inflammable. For a long time prior to the explosion, all the shots prepared in this mine each day were fired at one time by electricity, after the men had left the mine, and no explosion resulted under this system. The practice of firing all the shots simultaneously has also been in use in some of the Utah mines for years; and, up to the present time, the results have been entirely satisfactory. The same appears to be true of the Oklahoma mines, where simultaneous firing has been the practice for some time.

It is admitted that explosions may occur under this method of simultaneous firing; but the fact that they have not occurred where this supposedly highly dangerous practice has been adopted, indicates forcibly that widespread concussion, causing a general suspension of the dust in the air, in every part of the mine, and the general compression of the dust-laden air, and giving ample opportunity for the contact of flame with the raised dust, are factors not sufficient of themselves to cause the explosive combustion of the dust.

Since the rate of combustion, other conditions being the same, depends on the amount of available air supply, explosive combustion, by which the several dust particles aiding in propagating the flame must be burned as a whole, requires a larger air supply than mere inflammation, which requires but a partial combustion of the dust particles. The report of the British committee states: "The expansion of the gaseous products of combustion causes a movement of a column of air, which is pushed forward in front of the flame." This is true, but it is also evident that the complete combustion of the dust, considered by the committee as necessary to cause explosive effects, cannot be obtained by driving the air and fuel supply continuously ahead and away from the flame.

Effect of the Counter Current

My view is that explosive combustion of coal dust in a mine is produced initially and reproduced during the explosion's progress with the aid of a more or less pow-

*Late mine inspector, Chariton, Iowa.

erful dust-laden air draft that is especially active along the mine floor, moving in a direction opposite to the advance of the explosion. Evidence of the probable existence of this draft or "counter current," as I have termed it, in previous articles, in Coal Age, may be readily found in the comment of the British committee on the effects of the sudden rise of pressure caused by explosive combustion in the Altofts gallery. "This sudden rise of pressure," the committee says, "about 50 ft. from the open end of the gallery, sends an impulse back toward the closed end where the pressure was previously comparatively low. That is to say, the impulse is traveling in an opposite direction to that of the inflammation."

A cursory analysis of the cause and effect of this reverse "impulse" shows that the low-pressure area near the closed end of the gallery and the contraction of the gaseous products of combustion determined the direction of movement; and the suddenly increased pressure was due to the resulting explosive combustion; while the dissipation of pressure in the workings toward the closed end of the gallery created another low-pressure zone, which, in turn, caused the rearward movement of the dust-laden air that had been driven ahead of the flame and compressed by the expansive force. The pressure curves prepared from the manometer records taken in the Altofts experiments and given in Coal Age, Jan. 31, p. 207, show clearly that the sudden rise of pressure was followed by a correspondingly sudden decline, permitting the conclusion that the greater and quicker the reverse impulse sets in, the greater its magnitude and force.

In view of this fact, it is my opinion that as soon as the subsidence or contraction period begins after each explosive combustion stage, a dust-laden air draft starts to move toward the flame (this draft, naturally, being strongest along the bottom of the entry, and continues to move in an opposite direction to that of the flame, thus providing air and fuel for its propagation, until explosive combustion again takes place, when the draft movement is momentarily stopped, only to begin again as soon as the resultant fall of pressure occurs.

The Air Factor vs. Dust Factor

The recent discussion in Coal Age, Vol. 3, p. 3, *et seq.*, regarding Reducing Ventilation When Firing, shows the existence of a belief among mining men that the presence of strong draft is a material aid in starting a dust explosion. On the other hand, it is asserted that even an unusually strong air current directed against the flame of a blownout shot has little or no influence in the enlargement and propagation of the flame. Some hold the view that the presence of the dust is the all-important factor, while others believe that the amount of available air supply, rather than the available dust, measures the magnitude of an explosion.

These conflicting views regarding the value and influence of the air and dust factors in mine explosions, show the necessity of definitely determining, as far as may be possible, which side of the controversy is right. This is all the more essential, because the establishment of the true facts in the case will undoubtedly hasten the final solution of the dust-explosion problem. In order that progress in this direction may be made and knowing that Doctor Holmes, of the Federal Bureau of Mines, invites suggestions that may prove helpful, I take the liberty of offering the following as an experimental test to be made in the Bruceton mine.

A Suggestion for the Bureau of Mines

In order to determine whether or not extensive inflammation and explosive combustion of suspended dust can occur under conditions restricting the power of the "reverse impulse" to induce a strong draft of dust-laden air in an opposite direction to that of the flame, I would suggest that means, similar to those used at Altofts and described in the Fourth Report of the British Explosions in Mines committee, be adopted, in the Bruceton mine, to produce the simultaneous suspension of coal dust along the entire length of the main entry, from its mouth to the face; and that two strong doors, made as nearly air tight as possible and well braced, be located in the air course, inby of and near the junction of the diagonal entry and the air course. Shale dust should then be spread along the sides and on the floor of the air course from these doors to the face of the entry. All the crosscuts, but the one at the face, are to be stopped.

Just prior to making this experiment, the doors mentioned should be closed and locked in such a manner that considerable force will be required to open them, either in an outward or inward direction. In addition to the coal dust placed on the swinging shelves in the main entry, dust is to be spread on the floor and side shelves and in front of the cannon. The cannon is then to be placed at the mouth of the main entry, its muzzle pointing into the mine. The powder charge may be the usual one, 2½ to 3 lb. of powder. The firing of the cannot must be simultaneous with the upsetting of the dust-laden swinging shelves along the entry.

Should this test be made and extensive inflammation or explosive combustion not be produced, I would suggest that another experiment be then made, under the same conditions, except that a stout door be erected at the mouth of the entry and that the cannon be placed just inside of the closed door and fired into the mine, as before. Should this test, also, fail to cause an explosion, that fact would demonstrate quite conclusively, to my mind, that a large dust cloud may be subjected to concussion, compression and the impact of flame without explosive combustion resulting therefrom. The absence of draft facilities will, I believe, prevent the comparatively unrestricted dust-carrying air movement in an opposite direction to that of the flame that supplies the air and fuel necessary to enlarge, renew, and extend inflammation.

Should these tests result in explosions, that fact will not affect their value in any way, for it has been demonstrated at the different experimental stations, that a change in the conditions surrounding the making of tests brings a change in the results; and it may reasonably be expected that, in any event, the suggested experiments, made under unusual and untried conditions, will bring out new facts and useful information.

It has been rightly said that the process by which explosive combustion of the dust is effected must be definitely known, in order to determine what means should be adopted for the prevention and limitation of explosions. The correct answer to the question, How does coal dust explode, has been sought for many years, but has not, as yet, been found. I believe there is more than a possibility that this answer may be supplied by making the experiments suggested above.

Longwall Mining in Kansas

By Barry Scobee*

SYNOPSIS—The lower seam in the Mineral field, south of Pittsburgh, has been practically exhausted. The operators are preparing to mine the upper seam by the longwall method. The writer describes some of the conditions encountered, and gives, in part, the scale agreed on in this connection.

Several important coal operators and the officials of District No. 14, U. M. W. A., recently agreed on a wage scale and terms for mining by the longwall method. This is something new in the district and even yet opinion is divided as to whether the room-and-pillar process would not be better. The longwall method, however, is recommended more substantially.

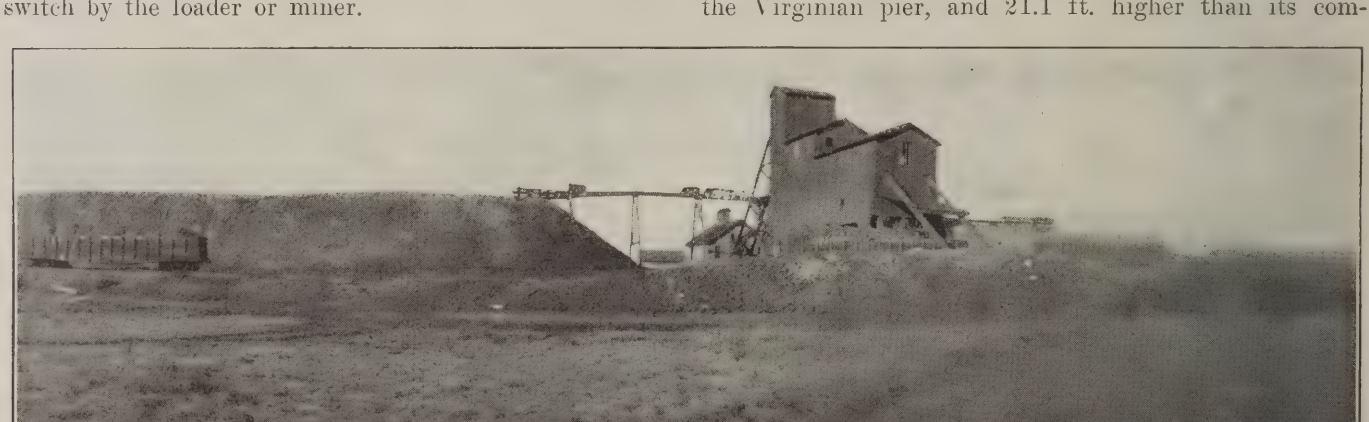
A New Mine, Clemens No. 4, North of Pittsburg, Kan.

Another Recent Development, Mine No. 19 of Western Coal and Mining Co.

The wage agreement was reached at Mineral, a town of 1500 people on the western edge of the coal field. This is an old field and practically all of the deep mines have been exhausted. The formerly important Missouri, Kansas and Texas shaft No. 8 is an example. The men have been quitting all winter, as they worked out their rooms.

There is, however, a shallower seam than the one these mines have taken out. It lies at an average depth of about 60 ft., while the old seam is nearly 200 ft. down. The upper seam is between 26 and 30 in. thick and is known to be six or seven miles wide. The length is a matter of speculation. The coal has no faults, is of good quality, and thus far, untouched. The current opinion is that it will profit the owners as much as the deep seam; and that it will be "the making of Mineral" if it is worked, for the town has been losing population by the miners going to the field north of Pittsburg.

J. H. Hibbens, of Parsons, representing the Missouri, Kansas & Texas; John Mayer, of Kansas City, a big operator in the district; William Barrett, on behalf of the operators; and George Richardson, arbitrator for the operators, met with the district officials and spent several days in arranging the plans. These men represented parties who are interested in the Mineral field; and Mr. Mayer and the Missouri, Kansas & Texas have idle machinery now which they will use when the top seam is opened. The miners also have homes in Mineral which they must leave if it is not opened, so that everything is favorable. Mr. Mayer has stated that he will open the top seam in the immediate future.



This field, owing to the lower seam being worked out, is being deserted. The towns of Arma, Edison, Ringo, Franklin and Capaldo have sprung up in the field north

*809 N. Walnut St., Pittsburg, Kan.

of Pittsburg and absorbed miners leaving the south end. Within the past year or less the following mines have been opened in the north end: Wear, 1; Central Coal & Coke Co., 2; Western Fuel & Mining Co., 2; Sheridan Coal Mining Co., 2; Clemens, 2; and Pittsburg-Cherokee Coal Mining Co., 1. These mines are about 200 ft. deep and the coal is 36 to 40 in. thick. Most of the mines are dry and shotfiring accidents are common.

Following is the scale, in part, as arranged in the conference, for longwall mining, or, at least, for taking out the upper seam:

Loading price is 60c. a ton of 2000 lb., the coal to be free from all slate, dirt, bone, sulphur, blackjack and other impurities, and to be delivered to the working switch by the loader or miner.

An Old Kansas Mine of Missouri, Kansas and Texas Co., near Mineral, Kan.

The cutting price is 30c. per ton of coal undercut and loaded, and it will be divided 16c. to runner and 14c. to helper.

The following prices for brushing apply: For roadway 4 ft. 6 in. above the rail, per yd. $1.56. Higher brushing in proportion. Where bottom-room brushing in rooms is required, it is to be paid for at the rate of 30c. per yd. for first 6 in., and 4c. for each additional inch.

Development in Coal-Loading Docks

An increase of about 20 per cent. in the tonnage of American railways furnished by the products of mines during the last five years has required the provision of elaborate terminals of special designs to handle the various classes of this low-grade traffic. Only six coal unloading plants classed as mechanical were in operation in Atlantic ports up to 1910, all of these being in New York harbor. One of the six was a belt-conveyor outfit, hoisting the coal from a track hopper to a height sufficient to allow it to be dumped into boats. The other five were all car-dumping machines located at a proper height to dump directly into boats, the road cars being pulled up in most cases by a barney. The remaining 50 docks located at the four Atlantic ports which load bituminous coal on ocean-going vessels were of the gravity type, the road cars being pushed or pulled to the top of a trestle on the pier from which the coal is dumped into boats.

In spite of the fact that more coal from the West Virginia fields is hauled to the Northwest since the acquisition of the Hocking Valley by the Chesapeake & Ohio, and in the face of increased competition for the West Virginia seaboard coal traffic, which followed the completion of the Virginian and the Carolina, Clinchfield & Ohio, the Norfolk & Western has more than doubled its traffic in bituminous coal during the last five years, and the tonnage delivered to vessels at this company's terminal at Lambert's Point in the Norfolk harbor during 1913 was more than 46 per cent. of the total tonnage handled in this harbor. This heavy traffic made advisable the construction of a new loading dock which is not as long as several of those already in service in the New York harbor, but it has more spouts than any of the gravity or simpler mechanical devices and the same number as the combination dock of the Virginian. It is 22.3 ft. higher than the Virginian pier, and 21.1 ft. higher than its companion gravity pier No. 3, at Lambert's Point, which formerly had the maximum capacity and the greatest height on the seaboard. The self-propelled pier cars are similar to those used on the Virginian docks, and have some common features with those used on the Canadian Pacific unloading dock at Fort William, but are of much greater capacity than either of the other designs.

By the replacing of one of the old gravity docks with this new combination mechanical gravity plant, the total rated capacity of the Norfolk & Western terminal was increased from 3150 tons per hour to 7875 tons per hour. The maximum capacity of a coal-loading dock must be greatly in excess of the average output on account of the necessity for loading large cargoes rapidly in order not to delay the vessels. In general, the output of the coal piers on the Atlantic coast averages about 30 per cent. of their maximum capacities, but the new pier at Norfolk could have loaded all the coal shipped from Lambert's Point in 1913 by working at its maximum rated capacity for only 13 hours per week. While the rating of 90 tons per minute for this pier is unusually high, it has been shown during the three months that the new pier has been in operation that it is not only capable of developing this capacity, but it has actually exceeded the rate for one dumper already, and probably will considerably exceed the total rate when both dumpers are put in service. —*Railway Gazette.*

Seams liable to spontaneous ignition should be worked by a method which facilitates the stopping-off of a district so that when a fire occurs the portion affected may be shut off without interfering with the rest of the mine. The panel system of working is best suited to such a seam.

A Triangulation Survey of the Fairmont Region

By A. W. Hesse*

SYNOPSIS—A description of one of the largest surveying projects ever undertaken in the coal industry. It involved precise control of a territory 90 lineal miles in length and comprising an area of 250 square miles. A description of both field and office methods employed.

In mapping immense tracts of land, before any of the ordinary surveys with transit and tape are made, it is necessary to secure control of the territory by primary, and perhaps secondary, triangulation surveys, if a high degree of accuracy is desired.

All the work of the United States Geological Survey is based on this system in obtaining the data for the construction of the geological and topographical maps and folios. In order to get the proper relation of points in various parts of the United States, astronomy is employed and determinations of latitude and longitude, in relation to Greenwich, are made at these points. Then they are connected by the primary triangulation survey. The astronomic determinations, being very accurately made, serve as a check on the primary triangulation survey made between these points. Then the secondary survey stations are located at shorter distances apart within the primary survey triangles, and are checked on the latter. The transit and tape surveys are then checked on the more accurate points of the secondary triangulation survey stations without running over excessive distances. Not much over two miles should be run without being "tied in."

Methods of Triangulating

This is the system employed in the fabrication of the surveys of the Consolidation Coal Co., mentioned in my article in Coal Age of Feb. 21, 1914, except that the astronomic determinations were omitted and the U. S. G. S. stations were used for checking the coal company's surveys.

Triangulation consists in surveying by triangles, the side of one forming the side of an adjacent triangle, as shown by *A* in the accompanying Fig. 1, in which the side *BC*, of the triangle *ABC*, is also the side of the triangle *BCD* and the side *CD*, of the triangle *BCD*, is also the side of the adjacent triangle *CDE*. Therefore, if the side of a triangle and the interior angles are known, the other two sides can be computed.

The first step then is to locate the points forming the adjoining triangles, so that clear sights can be obtained from one to the other. Next a base line is established, serving as a side of a triangle at each end of the system (and if the survey is long, an interior or intermediate base line), so located that they can be accurately measured. Then, in the accompanying figure, assuming *AB* and *DE* are measured and the interior angles known, when the other sides are calculated there will obviously be one common to each origin somewhere between, which will determine whether the work has been performed correctly. Or when the side *DE* is calculated, starting from *AB*, the result must be the same as obtained by actual measurement.

The maps shown in Figs. 2 and 3 are the triangulation survey made in the Fairmont Region for the Fairmont Coal Co. These surveys were started back in 1901 by H. V. Hesse, then chief engineer of the Fairmont Coal Co., and it was under his supervision that the bulk of the work was completed. Extensions to the main survey were made from time to time until the whole territory was controlled in 1909.

The properties now covered by this work are owned or controlled by the Consolidation Coal Co. In straight lines, the surveys extend over a distance of 90 miles, covering an area of about 250 square miles and requiring about 230 hubs or stations. These stations usually consist of a short bar or heavy rail, driven into the ground about three feet and the top center-punched. As each station was established it was described in reference to nearby trees or other available objects of the most substantial nature.

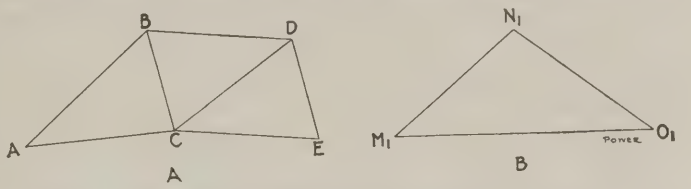


Fig. 1. Showing Series of Connected Triangles

The true meridian formed the basis of all the courses or bearings of this system and was established at Mine 56, near Watson. When this had been carried to the Government stations, it was checked against the bearings of the sides forming the angle at each station.

Base Lines

Measurements of the base lines were made while the transit readings of the angles were being taken. The first two base lines measured are located at Beechwood and Ehlen, about 25 miles apart. The description of the measurement of one base practically describes all of the six lines measured.

The first step in the determination of the length of a base line is to standardize the tape; that is, find at what temperature and pull it is U. S. standard measure. The tape manufacturer can furnish this information or it can be compared with the steel tape duly certified by the Bureau of Weights and Measures, at Washington. The tape used on this work was standard at eight pounds pull and 62 deg. F., and was 300 ft. long.

There are certain variable factors which also enter into the measurement of a base. These are errors, due to difference in temperature and pull and difference in sags caused by the variation in pulls. Consequently, corrections must be made for the same.

In Merriman and Brooks' "Handbook for Surveyors," page 87, are shown the formulas we used, which are as follows:

*Assistant chief engineer, the Consolidation Coal Co., Fairmont, W. Va.

$$temperature = +e(T - t)l$$

$$pull = +s(P - p)l$$

$$sag = -\tfrac{1}{24}\left(\frac{wl}{nP}\right)^2 l$$

e = Coefficient of expansion;
s = Coefficient of stretch;
p = Standard pull;
P = Pull of measurement;
t = Standard temperature;
T = Temperature of measurement;
n = Number of equal spaces in l;
w = Weight in pounds per lineal foot of tape;
l = Observed distance;
L = Mean adjusted distance;

Knowing the standard pull for the tape, the coefficient of expansion is determined by marking off accurately about 200 ft. on the floor of a large room, at the same time noting the temperature. This latter is then raised or lowered and the distance again measured and the operation repeated several times, the pull always being the same in each case. The change of length in each measurement is accurately observed and divided by the 200 ft.; this result is then divided by the difference in temperatures, in degrees, of the two readings. The result gives the coefficient of expansion. The several results are, of course, averaged and the mean adopted. The value obtained for the tape used was $e = 0.0000063$.

The next factor required, for use in the correction for pull, is the coefficient of stretch. This is necessary since the tape is used under different tension and the relative change in length for one pound pull must be determined. The operation is the same as that described for the coefficient of expansion, except in this case the temperature is maintained the same while the tension is varied. Then the coefficient of stretch is the difference in lengths divided by the total length, and that result divided by the difference in tension in pounds. In the coal company's determinations these pulls varied from 8 to 12; 8 to 16; 8 to 20; 12 to 16; 12 to 20, and 16 to 20 lb. The average result of these operations gave as the coefficient of stretch, $s = 0.000013645$.

Field Work

As previously mentioned, the base line formed one side of a triangle, the stations being substantial hubs. The base line was first laid out in divisions of about the length of the tape, in this case 300 ft., and stout stakes set at such division points. These were all on line between the ends of the base. On each division stake was placed a sheet of tin on which a fine mark was made at right angles to the line of measurement. After the stakes were set, elevations were obtained on the tops, and more stakes were set dividing each division into equal subdivisions of 50 ft. This usually made n, in the given formula, equal to six. The subdivision stakes were likewise placed on line and small nails driven into the tops to keep the tape in position while measuring.

The Ehlen base line consisted of four divisions, each of which contained six subdivisions, except the fourth, which contained five of 49 ft. each. The entire line was measured five times; six measurements were made of each division three times and eight measurements of each division made twice, making a total number of 136 measurements, of which 120 were used in calculating the line. The accompanying field notes will illustrate how these readings were taken and recorded for one division.

MEASUREMENT OF EHLEN BASE

12-11-01

Party { Kinkley, Smort, Jones, Hames } Division IV n = 5 3 p.m.

Pull	Temp.	Distance	
8 lb.	50°	245-12.45 = 243.963	
10 lb.	49½°	245-12.62 = 243.948	
12 lb.	49¼°	245-12.50 = 243.958	Day clear
8 lb.	48¾°	245-12.38 = 243.968	
10 lb.	49°	245-12.58 = 243.952	No wind
12 lb.	49°	245-12.60 = 243.950	

Spring balances were used at each end of the tape, one end of which was held stationary over the stake while the other was pulled until the proper strain was obtained when the reading was taken. In the above case, the 245-ft. graduation was a fraction more than 12 in. over the division length, the difference being read by an engineer's scale, graduated to fiftieths of an inch, making it possible to read to hundredths.

In a book, kept specially for the purpose, these measurements were rearranged and each division worked out by itself, as shown by the accompanying notes.

73¼	16	243.881	0.0173	0.0266	0.0083	243.917

Mean observed distance = = 243.926
n = 5 h = 0.377 ft.
Mean adjusted distance = 243.9141
Final horizontal distance = 243.9138

These notes give some idea of the variations in measurements caused by a difference in temperature and pull. It will be noted that the average of the observed distances is 243.926 ft. Taking this as l and substituting in the formulas for corrections heretofore given, they reduce to

$$correction\ for\ temperature = +0.0015367\ (T - 62)$$

$$correction\ for\ pull = +0.0033284\ (P - 8)$$

$$correction\ for\ sag = -\frac{2.12595}{P^2}$$

Where the pull equals 8 lb., the correction for pull reduces to zero and the algebraic sum of the corrections and observed distance gives the adjusted distance. After all the adjusted distances were worked out, the average of the results was taken as the final adjusted distance, in this case being 243.9141 ft. The difference in elevation between the hubs of this division was $h = 0.377$ ft. Therefore, taking the square root of the difference of the squares of the mean adjusted distance and the difference of elevation, we get the final horizontal distance, 243.9138

ft. ($\sqrt{L^2 - h^2}$). Thus each division of the base was worked up and the sum of the distances gave the final length of the base line.

All of these calculations were worked out by naturals in duplicate to avoid the slightest possible error. Copying and recopying were always checked and marks indicating that results were correct had to show this fact.

Angle Observations

The observations of the angles of all the triangles are illustrated at B in the accompanying Fig. 1 and in the notes. In the triangle $M_1O_1N_1$, the readings on angle O_1 are here given:

Aug. 26, 1901 — Party { Molt, Jones, Charles, Johnson, German.

4	334° 15′ 30″	29° 01′ 15″	

Mean 29° 01′ 18.13″. Weight 2

In these readings each series was read on the A vernier, while in most cases later the B vernier was read when the telescope was reversed, thus eliminating errors due to angular distance between the verniers and to any eccentricity of the graduated limb.

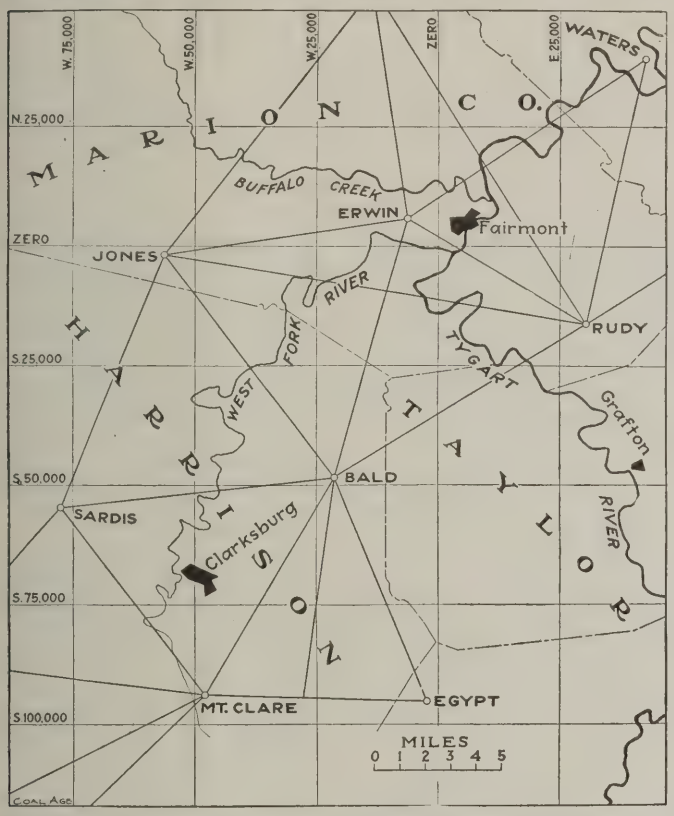

Fig. 2. Primary Triangulation Survey; Fairmont-Clarksburg Region

The instrument used had vernier graduations to read 20 sec. direct, making it possible to estimate to 5 sec. When readings were started the vernier was set by naked eye to the starting point, then read with a magnifying glass and recorded. These readings are shown opposite A, as found in each particular case. In the first two series, the backsight was taken on M_1 and the angle turned to N_1, where the vernier was clamped. After the reading was taken the spindle was unclamped and the backsight again taken on M_1 without resetting to the original starting point, but each angle being added to the one previously read, thus making cumulative readings. Subtracting A from each of the following readings and dividing by the number opposite to the left, gives the reading recorded on the right. In the first two series A is subtracted from the readings which follow, while in the last two each reading is subtracted from A and divided by the number opposite.

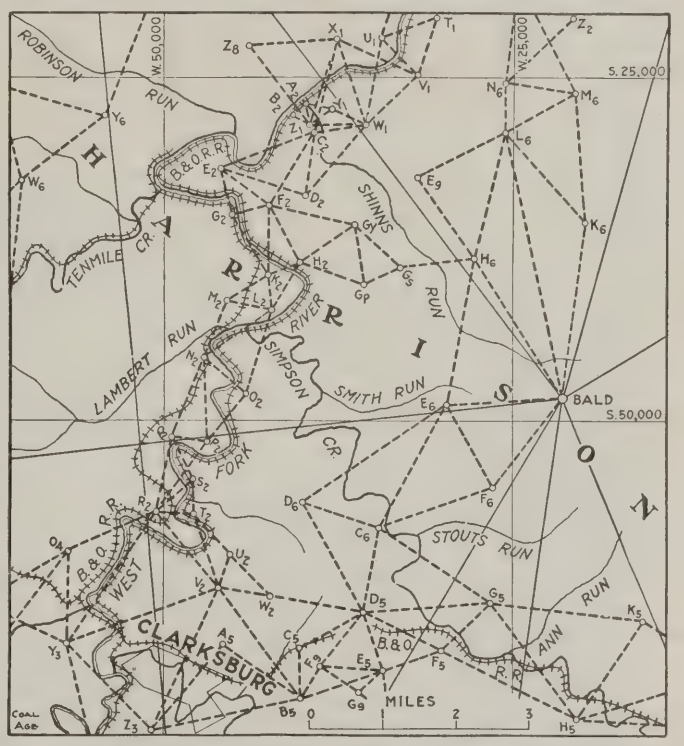

Fig. 3. Showing Triangulation Survey in Vicinity of Clarksburg, W. Va.

The "mean" result is the average of the four average results to the right. The weight 2 designates the condition under which the readings were taken. Weights were used from 1 to 5, inclusive. Number 1 represented excellent conditions, while number 5 represented the worst. These weights were used in distributing the error of closure when the triangle was adjusted. This may be shown by the triangle in which the angle O_1 formed a part:

	$M_1 - N_1 - O_1$			Corrected
$M_1\ N_1\ O_1$	128° 39′ 39.06″	+ 1.74″	=	128° 39′ 40.80″
$N_1\ O_1\ M_1$	29° 01′ 18.13″	+ 1.16″	=	29° 01′ 19.29″
$O_1\ M_1\ N_1$	22° 18′ 58.75	+ 1.16″	=	22° 18′ 59.91″
	179° 59′ 55.94″	+ 4.06″	=	180° 00′ 00.00″

Here, the error of closure was —4.06 sec., and the weight on the angles N_1, O_1 and M_1 were 3, 2 and 2, respectively. Therefore, N_1 took three-sevenths of the error, while O_1 and M_1 each took two-sevenths of the error to make the sum of the angles equal 180 deg. In only the most extenuating cases were errors of closure

allowed to stand, which exceeded 5 sec., this being the set limit.

After the adjustment of the angles came the calculation of the distances or sides of the triangles. The well known trigonometric formula: "The sides of a triangle are proportionate to the sines of the angles opposite," was used. Thus in the given triangle $M_1N_1O_1$, say the side M_1N_1 had been previously calculated, then:

$$\frac{sine \angle O_1}{sine \angle N_1} = \frac{M_1N_1}{M_1O_1}$$

which, by transposition, becomes

$$M_1O_1 = \frac{M_1N_1}{sine \angle O_1} \times sine \angle M_1$$

Also

$$N_1O_1 = \frac{M_1N_1}{sine \angle O} \times sine \angle M_1$$

Then one division serves for both equations. These calculations were performed by naturals, the sines of the angles being carried to ten decimal places in order to determine the ninth. In the division of M_1N_1 by the sine of $\angle O_1$, the result was carried to five places to determine the fourth, and likewise, the results of the multiplications were adopted to four decimal places.

Computing the Distances

In the calculations of the sides of these triangles, the base line at Beechwood formed the side of the first triangle at that end and the base line at Ehlen formed the side of the first triangle at that end. Then somewhere between there was one side which had to be calculated from adjoining triangles. When the work from each way met, the difference between the calculated lengths amounted to 24 ten-thousandths of a foot (0.0024 ft.). Thus the surveys were checked all through the system.

The next step consisted in obtaining courses between the various stations. As previously stated, the true meridian had been established near Watson and transferred to a side of one of the triangles from which all the other sides were calculated by means of angles between the sides. One method was by addition and the other by subtraction, and the results checked one against the other. Thus, say the azimuth of the side M_1N_1 of the triangle $M_1N_1O_1$ is:

	Addition		Subtraction	
	M_1N_1 = 129° 13′ 50.05″	Reverse	129° 13′ 50.05″ =	M_1N_1
Add	M_1 = 22° 18′ 59.91″	Get	309° 13′ 50.05″ =	N_1M_1
		Subtract	128° 39′ 40.80″ =	N_1
Reverse	M_1O_1 = 151° 32′ 49.96″			
And get	O_1M_1 = 331° 32′ 49.96″	Reverse	180° 34′ 09.25″ =	N_1O_1
Add	O_1 = 29° 01′ 19.29″	Get	360° 34′ 09.25″ =	O_1N_1
		Subtract	29° 01′ 19.29″ =	O_1
Reverse	O_1N_1 = 360° 34′ 09.25″			
Get	N_1O_1 = 180° 34′ 09.25″	Reverse	331° 32′ 49.96″ =	O_1M_1
Add	N_1 = 128° 39′ 40.80″	Get	151° 32′ 49.96″ =	M_1O_1
		Subtract	22° 18′ 59.91″ =	M_1
Reverse	N_1M_1 = 309° 13′ 50.05″			
Get	M_1N_1 = 129° 13′ 50.05″		129° 13′ 50.05″ =	M_1N_1

After the azimuths and distances of the side of each triangle were calculated, the quadrants or courses were easily obtained from the azimuths and the latitude and longitude differences were computed by naturals. In these calculations also, were the sines and cosines carried out to nine decimal places. Having obtained these differences, the zero point of the coördinate system was placed at Mine No. 56, near Watson, and total latitudes and departures were worked up for all the stations from this point.

The values on each station were checked by working in both directions around the triangle. For instance, in the triangles ABC and BCD, previously given, the point A being taken as zero, say B is north 2000 ft. and east 1000 ft. from A, therefore C must be south 1950 ft., and east 1000 ft. from B by calculation from the course and distance between them, if C is north 50 and east 2000 from A. Likewise, d must receive values from b and c that coincide, and all the way through the system, the values on the stations received from the different points must check. At some places, quadrilaterals were used and the same line would be calculated from different sources.

Latitudes and Departures

After all the coördinate values were placed in the record book, together with the other data of the survey, such as azimuths, quadrants, etc., shown on a regular traverse sheet (see Coal Age, Feb. 21, 1914), the elevations on the stations were calculated from the vertical angles taken between stations and the previously calculated distances. The sights on the rod were taken on the top and the correction made for the 8-ft. difference Set-ups were made on each station, thus checking one reading and calculation against the other.

Say from A to B the reading was plus 2° 50′, rod 8 ft., and the reading from B to A was minus 2° 19′, rod 8 ft., and the distance between the points 1000 ft. The height of instrument at A was 4 ft. and at B it was 3.50 ft. Then from A to B we get plus 49.05 — 8 ft. (rod) plus 4 ft. (instrument) equal to plus 45.05 ft. From B to A, we get minus 40.43 ft. minus 8 ft. plus 3.50 ft. equal to minus 44.93 ft. In places where it was difficult to get these verticals to correspond, precise levels were run to the stations and checked back on the bench mark. The elevations on the triangulation stations served as checks on the elevations carried by transit and tape surveys. The calculation of vertical distances was performed by means of naturals and logarithms carried to seven decimal places.

This triangulation survey now forms the framework of all other surveys in the field. The results and benefits derived from this work have already proven invaluable in many ways.

The Consumption of Water in Anthracite Mines

The desert of Sahara, where they occasionally kill and cut open a camel in order to get the water which it contains, is not the only place where water is a valuable salable commodity. Right at our doors, in the anthracite mines of Pennsylvania, the operators pay out nearly $600,000 a year for pure, fresh water. This is necessary, after pumping over 1,000,000,000 tons, or approximately 300,000,000,000 gal. of water a year out of the mines.

Mine water is plentifully charged with sulphur, and the disastrous effect of the sulphur upon iron necessitates the frequent renewal of the hundreds of miles of pipe in the mines. A pipe line laid new early in April has been known to be ruined by July.

One company bought 1,316,369,963 gal. of water last year for which it paid $109,494.76, and consumed nearly 100,000,000 gal. at one colliery. The total quantity of fresh water bought by the anthracite coal operators last year is calculated to be 7,115,573,324 gal. and the cost $591,863.56.

Wire Ropeways for Coal Transport

SYNOPSIS—The wire ropeway often is found more adaptable to mining operations than the railway. It is not usually subject to the formation and configuration of the land; and it is both simple of construction and inexpensive of operation.

It is not always possible to arrange matters so that the railway siding is immediately adjacent to the most convenient loading point of a colliery, and in some cases the question of transport between a colliery and the main line railroad, or shipping point, becomes a matter of serious difficulty. It is of interest therefore to examine the alternative method of transmission by wire ropeways, which has been developed to a very considerable extent in Germany and elsewhere, and we are indebted to Messrs. A. W. Mackensen, of Schoeningen, for details of some of the plants of this type which they have constructed.

FIG. 1. WIRE ROPEWAYS. NOTE THE PROTECTION BRIDGE ERECTED OVER THE ROAD CROSSING TO INSURE PUBLIC SAFETY

ADVANTAGES

It is claimed that with modern methods of construction the results obtained with suitably erected wire ropeways are so favorable that, nowadays, if two points are to be connected, the wire ropeway may be as readily taken into consideration as an ordinary railway. The most important advantage of a wire ropeway, as compared with a railway, is that the former is dependent neither upon the configuration or formation of the ground over which it has to pass. It can cross roads and other obstructions at the required height without being a hindrance to the traffic below, as cables can be suspended from points 1000 yd. or more apart, deep valleys and rivers can be negotiated. A wire ropeway is also suitable for a steep mountain side. Moreover, a railway often has to be laid in curves, owing to the natural formation of the ground or to the necessity of avoiding private property, public roads, etc., while the difficulty of making a straight wire ropeway for any of these reasons is much less. Consequently, the wire ropeway is often shorter than the equivalent railway, leading not only to a lower cost but less operating expense. The latter point is also secured by the fact that the wire ropeway works entirely automatically except at the end stations, and even there the loading and unloading of the cars can be accomplished with a very small amount of labor because of the easy handling of the cars and the small loads carried in each unit. The wire ropeway is not influenced by weather as its working cannot be interrupted by snow, frost, floods, etc., and the construction or moving of such a line does not involve much time or expense. In case of difference of level, a saving of power can often be effected by balancing the

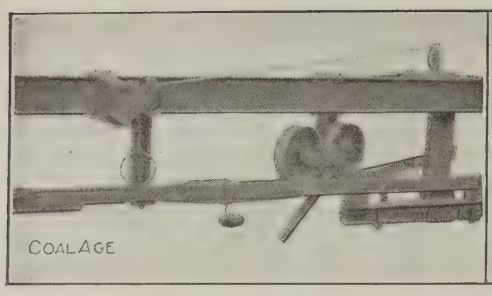

FIG. 2. THE MACKENSEN SYSTEM OF SIMPLIFIED SPECIAL SWITCH

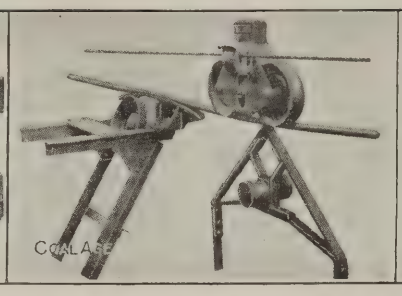

FIG. 3. A SPECIAL SAFETY CROSSING SYSTEM

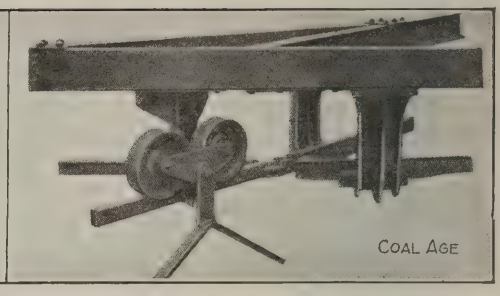

FIG. 4. A ROPEWAY CAR PASSING A SUPPORT

weight of the cars moving in one direction against that of those moving in the opposite direction on the return journey. As the wire ropeway can make such a good showing as compared with railways, it is evident that it is even more advantageously employed as compared with horse haulage.

DISADVANTAGES

A wire ropeway cannot, however, be compared with machines which are manufactured on a large scale and are then put on the spot where they have to work, because every ropeway must be planned differently in each individual case in order to suit the special conditions. The single parts cannot, as a rule, be calculated theoretically but can only properly be estimated on the basis of experience. The cars and other accessories must be able

FIG. 5. A PORTION OF A WIRE ROPEWAY ABOUT FIVE MILES LONG

to stand rough handling, and not only must the wire ropeway be free from danger of breaking at any point but it should also be kept permanently in good condition.

CONSTRUCTION FEATURES

The carrying ropes are generally of a closed construction and if only light loads are to be carried, or if the cost of construction is to be as low as possible, round wires are used. For traction ropes, cables of a special construction are adopted which go round large pulleys at the end stations and are always kept in tension by means of weights. If very heavy loads are to be conveyed, the weight is duplicated so as to be carried by four or more wheels, that is to say, by suspending a load from two single carriages, or by means of a special double trolley in which two single trolleys are combined by a connecting beam. An automatic coupling device is constructed on the principle that the clamps which hold the traction rope on both sides are pressed together by the weight of the car in such a manner that the frictional power is several times the weight carried. As a means of transmission, a wedge is used, which moves the clamps exactly parallel to themselves so that, as the rope is never pressed obliquely at any time, it attains its longest possible life. The pressing power can be exactly calculated and is maintained from the moment when the rope is gripped by the clamps until it is released. The proper working is not upset by wear on the rope or clamps, and a car can change from one line to another even if the traction ropes have differing diameters. It is not necessary to detach the car from the traction rope in taking curves as the cars will take these automatically.

The tilting of the cars at the station is usually accomplished by hand, but it is also easy to provide automatic unloading. This is specially useful for the purpose of building up heaps of material such as clinkers, coal, etc.

ILLUSTRATIONS

Fig. 5 shows a portion of a wire ropeway about five miles long, for transporting coal and clay. The capacity per hour is 140 cars of coal, containing 21 cu.ft., and 60 cars of clay of 14 cu.ft. Fig. 1 shows another wire ropeway for transporting coal and taking back mining timber, the feature of the photograph being a protection bridge erected over a road crossing and showing the simplicity with which safety to the public is secured. Figs. 2, 3 and 4 show, respectively, the Mackensen system of simplified special switch, a special safety crossing system, and a ropeway car passing a support. A good many other examples could be given of the application of the wire-ropeway system for coal transport, but, these are sufficient to show the importance of its various applications.

Immigration and Emigration

The Department of Labor reports the arrival and departure of aliens in the United States for the year ended June 30, 1913, and for the six months ended Jan. 1, 1914, as follows:

	Year			Six Months		
	Arrivals	Departures	Net*	Arrivals	Departures	Net*
July	78,101	24,673	+ 53,428	138,244	26,434	+111,810

* Indicates the net change in population from alien immigration and emigration movement.

High Records in Illinois

The mines of the Superior Coal Co., located at Gillespie and Benld, produced on Monday, Mar. 9, 1914, 13,431 tons of coal, as follows:

	Tons
Mine No. 1	4393
Mine No. 2	4430
Mine No. 3	4608

There was no special preparation for this record hoist, as the same mines hoisted 12,288 tons on the Saturday preceding, and made an average hoist for that week of 12,277 tons per day. Mine No. 3 hoisted in four hours, Monday afternoon, 2525 tons; which would, at the same rate, produce over 5000 tons in an eight-hour shift. The best single-day's hoist, made at No. 3, is 4748 tons.

The mines of the Superior Coal Co. ranked, in the Coal Report of Illinois, for the year ended June 30, 1913, as follows: No. 3 was second in the state, producing 837,834 tons, employing 675 men, working 216 days and making an average daily hoist of 3879 tons.

No. 2 was third, producing 828,288 tons, employing 665 men, working 215 days and made an average daily hoist of 3853 tons.

No. 1 was sixth, producing 681,852 tons, employing 659 men, working 212 days, and making an average daily hoist of 3216 tons.

In the Coal Report of Illinois, for the year ended June 30, 1913, there were 33 mines that had an annual production of more than 400,000 tons and 61 mines that produced more than 300,000 tons. The Coal Report of Illinois, for the year ended June 30, 1903, showed that four mines had a production of more than 400,000 tons and 15 a production of more than 300,000 tons.

This is a splendid increase in the number of large producing mines and the tendency is to a still greater producing capacity. In this connection, the following comparison shows an interesting growth:

	1903	1913
Shipping mines in operation	353	371
Total number of employees	49,814	79,497
Total tonnage	34,955,400	61,846,204
Mined by machines (tons)	7,646,777	30,228,520
Fatal accidents	156	175
Nonfatal accidents (30 days lost time)	410	1025
Death rate per 1000 men	3.13	2.20
Death rate per million tons of coal	4.46	2.83

Since the foregoing was written, we have been informed that the No. 2 and No. 3 mines of the Superior Coal Co., have each made a record hoist of more than 5000 tons of coal in an eight-hour day. Saturday, Mar. 14, No. 2 mine hoisted 5023 tons; and Thursday No. 3 tried for the 5000-ton mark and failed. They were able to hoist 4854 tons, but on Friday, Mar. 20, No. 3 jumped into the 5000-ton class and hoisted 5116 tons, which is at the rate of 639.5 tons per hour, or more than 10 tons a minute. In making the record at the No. 2 mine, 1562 mine cars were brought to the surface and it required 108 railroad cars to haul the coal away from the mine.

The mines last named, Nos. 2 and 3, are each shaft mines to the No. 6 seam and are 340 ft. deep; the coal is 7 ft. 6 in. in thickness and is mined by machines.

The Clam-Shell Mine Car

A new mine car has been designed by N. H. Mannakee, a mining engineer of Williamson, Mingo County, W. Va. It reduces the labor of dumping at tipples, head houses and bins. The cars need not even be uncoupled when dumped, and if discharged onto a moving apron, they would empty their load without any breakage. In any event, their manner of dumping is such that they are far less destructive to coal than the old end-gate car.

The Mannakee Mine Car Which Opens Like a Steam-Shovel Bucket

For work in a low seam, the car will carry a larger capacity than the ordinary steel or wood cars of the same height above the rail and the same outside dimensions in plan. This results from the fact that by the curvature of the axles, the car body is kept closer to the rail. These axles support the car and keep it true to radius.

The goosenecks or side arms which lift the jaws of

the bucket are raised slowly by the pushing or pulling of the car past curved guide bars on the side of the track. These bars are so shaped or bent that when the car is opened full they keep it in this condition for a distance about equal to the length of the car. The guides then curve downward to allow the shells to come together gently as the car passes onward.

Theoretically, the gooseneck should be lifted an amount equal to about one-half the size of the largest lump of coal to be discharged. In practice, probably a lift of 15 in. would be enough. This would provide an opening in the bottom of 30 in., and in the inventor's experience, he has found this opening sufficient.

It can be readily seen that a car with much greater capacity could be obtained by raising the sides. The bill of material, weights, etc., for a car for use in a low seam, follow:

BILL OF MATERIAL OF MANNAKEE CAR

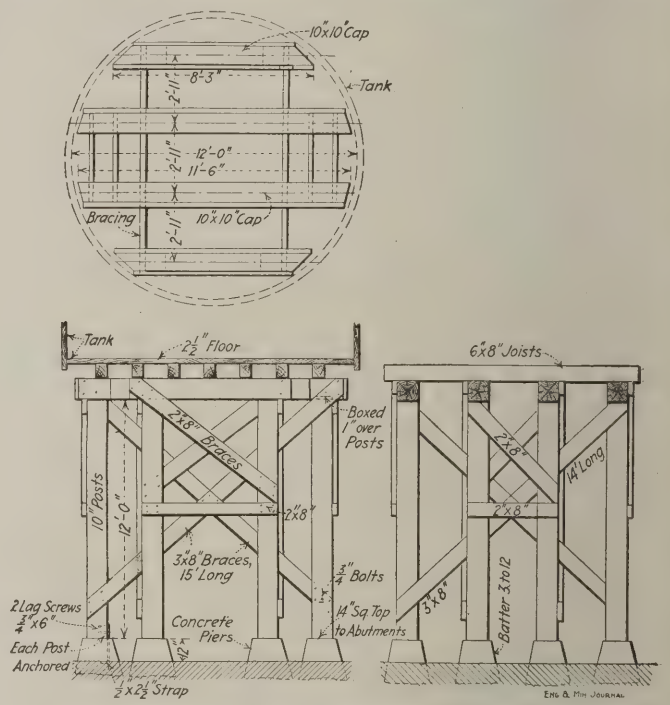
Pieces	Size	Weight	Description
2	2¼" sq.x57"	166	Axles
4	14" diam.	372	Wheels
4	¾"x16"x5"	18	Boxes
2	3"x5"x⅜"	473	Frame angles
2	Castings	400	End supports
2	¾"x48"x13"	125	Bottom bumper plate
4	⅝"x42"x2¼"x2¼"	82.6	Angles at ends
2	4"x1½"x18"	120	Side arms
1	2"x126"	112	Round shaft
1	2"x120"	30	Pipe
4	3/16"x4 sq. 7x7.65	135	Sheet steel ends
2	3/16"x9.25x7.65	500	Sheet steel side
72	½"	20	Rivets
65		140	Bolts
	Total	2683.6	

Capacity of the car level full = 133,159 cu.in. = 49.54 bushels allowing 2.688 cu.in. per bushel. Weight of coal estimated at 2.05 + net tons.

West Virginia Miners Outdig Canal Laborers

In the last three years the excavation incident to the mining of coal in West Virginia has been greater than the excavation required in eleven years to dig the Panama Canal.

When the engineers of the Panama Canal, in 1903, began their work, they made a careful survey and found that approximately 195,323,000 cu.yd. of excavation was necessary. This was regarded as a stupendous undertaking and was commonly spoken of as the largest excavation job the world has ever seen. Laborers were imported to the Canal Zone, and column after column was written showing how marvelously these laborers were "making the dirt fly" under the direction of the most expert engineers the world has ever seen.



But the 195,323,000 cu.yd., the original estimate, were not all that the Panama Canal laborers were to dig after they had started. On account of the slides in Culebra cut, another hundred million cubic yards were to be added to their work. This made 295,323,000 cu.yd., which were dug in eleven years.

Under conditions far more difficult, the coal miners of West Virginia were to do an amount of excavating in the same eleven years that would make the digging incident to the Panama Canal look like child's play. The work of these West Virginia miners has never been heralded to the world as the last word in excavation efficiency. As a matter of fact, the general public has paid little attention to it. But in the eleven years, while the much heralded work at the Panama Canal was producing 295,323,000 cu.yd. of earth—and all of the excavating was being done on the surface—the coal miners of West Virginia were getting out of the bowels of the earth 542,949,446 cu.yd. of coal. This was almost twice the amount of excavation of the Panama Canal, and it was done under far more difficult conditions.

Substructure of Wooden Water Tank

By William Wallace*

A necessary adjunct to every iron-range boiler plant is the water tank. The flat topography usually eliminates the possibility of setting the tank on high ground to gain head, and for that reason it is usually put near the boiler house. The latest tanks are of the elliptical-bottom steel

Posts, Stringers and Bracing to Carry Wooden Tank

type, raised to considerable height on a steel structure, but wooden tanks supported on a wooden substructure in the manner of railway tanks are still common. Such a substructure of standard type is illustrated herewith. It is built of sawed timber set on concrete piers and usually painted. The tank supported in this case is 12x12 ft.—*Engineering and Mining Journal.*

BY THE WAY

Those things we never had we can never lose.

It is easier to follow foolish precedents than to think.

Things sweetest to the taste often prove sourest in the stomach.

Exhaustive observation is an element of every great achievement.

Adjourning sine die seems to be the most popular indoor sport in the coal industry today.

Exclusive praise must not be given to the horse that wins the race—some belongs to the man that keeps the stable.

*Mining engineer, New York.

Who's Who in Coal Mining

Frederick William Whiteside was born at Chicago, Ill., Nov. 2, 1875. On his mother's side, Mr. Whiteside was a direct descendant of Captain Amasa Hungerford, of the Revolutionary Vermont troops, the Hungerford family having landed upon American soil in 1632.

Mr. Whiteside's education was obtained in the public schools of Denver, Colo., and at the University of Colorado, from which latter institution he graduated.

His first work on leaving the university was as assistant engineer with the Denver Union Water Co., and later in the same capacity with the Denver & Rio Grande R.R. Co. He then became division engineer of the El Paso & Rock Island R.R. Co., which position he left to take up his first work in coal mining as assistant engineer, with the Colorado Fuel & Iron Company.

F. W. Whiteside

But railroad work once again attracted Mr. Whiteside and he became chief engineer for the New Mexico Midland R.R. Co. However, he soon returned to the coal industry, becoming chief engineer of the Southern Fuel Co.

Mr. Whiteside is now chief engineer of the Victor-American Fuel Co. as well as other enterprises, such as marble, telegraph and railroad companies, besides being retained in a consulting capacity by the Keystone Fuel Co. He is Secretary-Treasurer of the Rocky Mountain Coal Mining Institute, and a member of both the Colorado Electric Club and the University of Colorado Club, of Denver. Mr. Whiteside has been a frequent contributor to the technical press of the country, and occasionally lectures at the educational institutions in Colorado.

Harry Mortimer Kanarr was born Aug. 31, 1876, near Deckers Point, Indiana County, Penn. Mr. Kanarr's early education was obtained in the public schools, which was followed up by a special mathematical course in the State Normal School at Indiana, Penn., and supplemented by home studies.

His first practical training was obtained under his father, and consisted mostly of land and property surveying. In October, 1902, however, we find him out on his own initiative, being employed as a transitman under Walter F. Arms, chief engineer of the Rochester & Pittsburgh Coal & Iron Co. His first work for this concern was in charge of the construction at the Ernest Mines, near Indiana.

Exactly one year later he was transferred to Iselin as

H. M. Kanarr

assistant to Robt. H. Wilson, chief engineer in charge of the construction of that plant. January, 1905, found him again transferred to Punxsutawney, where he became division engineer under Geo. D. Bartholomew, a few months later becoming Mr. Bartholomew's assistant. In May, 1907, he was appointed chief engineer in responsible charge of all the work formerly handled by all three of his previous employers.

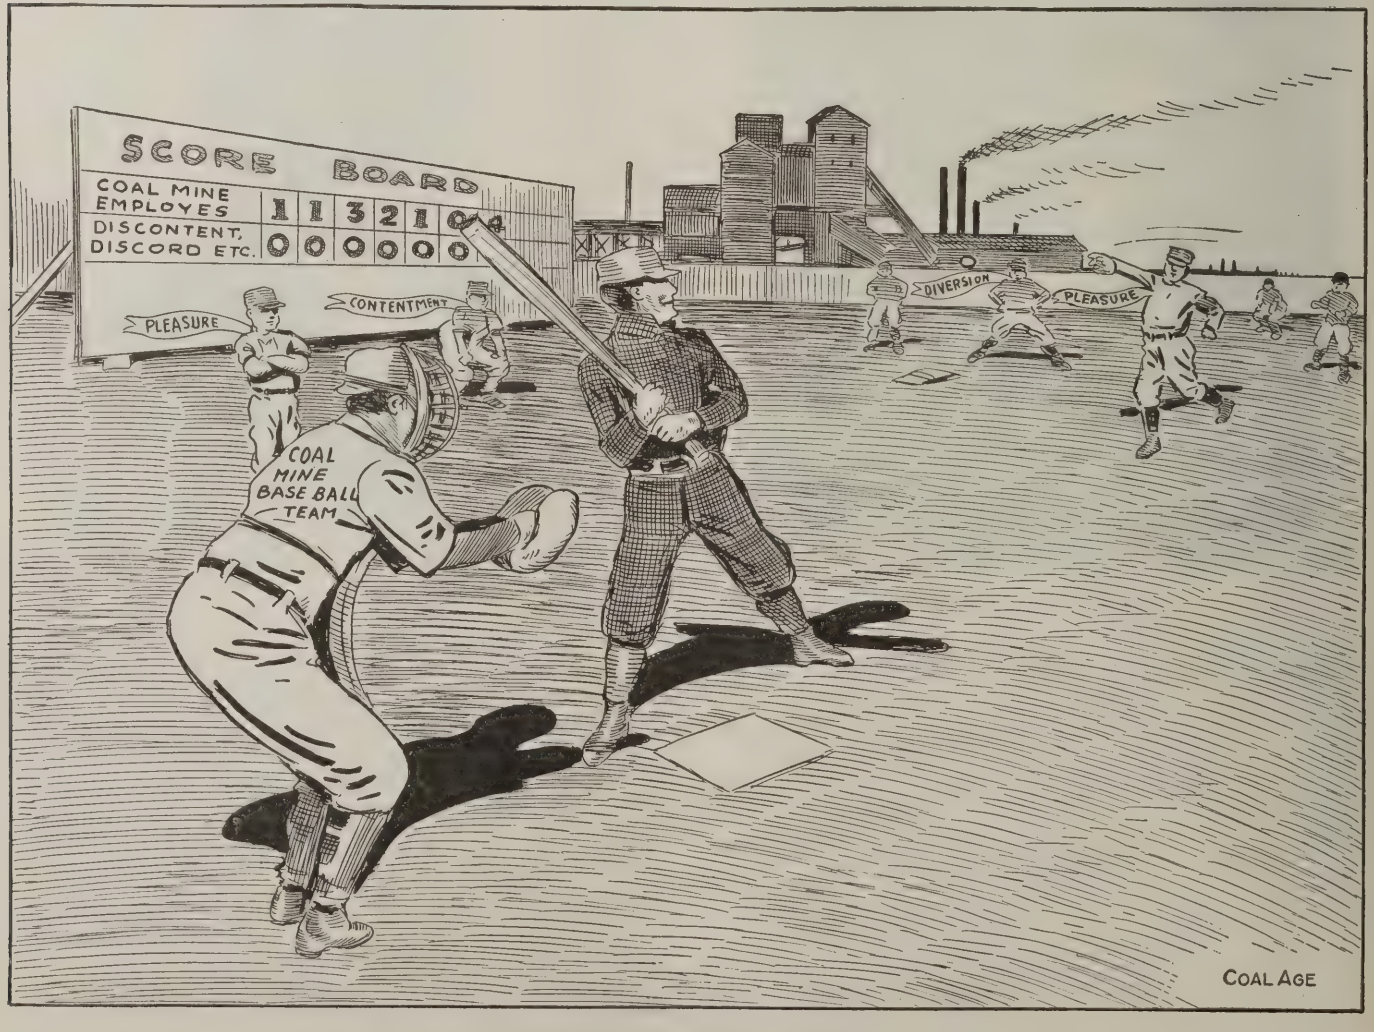
Mr. Kanarr is now chief engineer of the Rochester & Pittsburgh Coal & Iron Co., the Jefferson & Clearfield Coal & Iron Co., the Cowanshannock Coal & Coke Co., the Reynoldsville & Falls Creek R.R. Co., and at the present time, he is also serving as secretary-treasurer of the Hudson Coal Mining Co.

The Labor Situation in Ohio

Walter R. Woodford, president of the Eastern Ohio Operators' Association, is preparing a suit to be filed as soon as possible to test the validity of the Ohio screen-coal bill. There is a question as to whether this case can be brought before the law becomes effective on May 20. In the meantime, the operators of Ohio are waiting for developments.

George Savage, secretary of the United Mine Workers of Ohio, has announced that steps will be taken immediately toward bringing about a joint conference with Ohio operators.

Every mine in Ohio closed Tuesday night of last week; Wednesday, eight-hour day meetings were held in all of the principal coal mining centers. President John Moore, of the United Mine Workers of Ohio, addressed a mass meeting in Bridgeport. He prefaced his remarks by calling upon the miners to remain loyal to the organization and admonished them against socialists and the Industrial Workers of the World. The latter organization at the present time is attempting to rouse miners of the No. 8 district.



A Split in the Union Ranks

At Roseville, the local union passed resolutions calling upon John P. White, president; Frank J. Hayes, vice-president; and W. O. Green, secretary-treasurer of the United Mine Workers of America, together with the members of the policy committee of the union, to resign. The Roseville union charged that the negotiations and policy of the officials were not satisfactory nor to the best interest of the men. The resolution was forwarded to all of the unions in Ohio with a request that similar action be taken.

This movement and the defection of miners are so serious that Mr. Green will address the Crooksville, Ohio, union Tuesday. He will ask for explanations. A circular mailed out from the headquarters in Indianapolis, Saturday, exhorts the miners to remain loyal and advises them to support the officers in the referendum being taken on the policy adopted by the committee.

The failure to win the mine-run wage scale throughout the state has caused the miners to attempt to make local settlements. None of the companies has shown any intention of weakening. The miners have not succeeded in getting conferences in the sub-districts and it looks as if nothing will be done except as a state organization.

Miners are not all of one opinion, but the majority of them are convinced that the mines will generally remain closed until the mine-run law has been tested in the courts. They do not expect to have work until late in the summer in most instances.

The Real Base Ball Team

Editorials

The Present Industrial Idleness

To judge by the dailies of our various cities, the country is now menaced with an army of unemployed, larger and more desperate than we have known for years.

Our newly appointed Federal Industrial Commission has been seriously enough impressed by the facts as reported, to feel justified in ordering an immediate investigation, looking toward action by the Federal Government, to relieve unemployment. Frank P. Walsh, chairman of the commission, is quoted as saying: "Groups numbering from 100 to 1000 stand outside our great industrial plants each morning at six o'clock, hoping the foremen will pull them out of line and put them to work. They are thankful if they get only a few hours' work.

"Poorly nourished and thinly clad, these men gather each morning and then drift away to the cheap saloons or cheap lodging houses to wait for any other chance.

"None can see this spectacle without realizing that it is something society cannot afford to tolerate. An employer never thinks of laying off his bookkeeper or clerk after employing him three or four hours in a day or three or four days in a week.

"The problem of continuous employment for laborers is more difficult, but it is a problem that must be solved if we are to check the increase in our great army of hopeless, homeless men. If nothing else will avail, it may be necessary to urge insurance against nonemployment."

Now would be a good time for some of you mine owners to invite the reporters from some of these same dailies to inspect your diggings; especially the fellows who always refer to you in graphic sneers. In spite of the fact that the coal trade has been extremely dull this winter, our coal-mining camps are not infested by hungry bands seeking employment and such spectacles as Mr. Walsh describes are almost unbelievable to coal miners in America.

A Smell Is a Smell

Kipling has stirred up a very lively discussion in England by publishing the following lines: "I suggest, subject to correction, that there are only two elemental smells of universal appeal—the smell of burning fuel and the smell of melting grease. In other words, the smell of what man cooks his food over and what he cooks his food in."

If Kipling ever visited a mine, his smeller must have been off duty, or else he forgot the experience before he wrote the above lines. And even at that, we insist that his wits must have been wool-gathering when he sat down to write. Before man can start a fire to cook food, he must have the fuel and the food, and while he is digging these up, the real elemental smell comes into being. You can trace it back to Genesis; "In the sweat of thy face shalt thou eat bread, till thou return unto the ground."

At a coal mine, equipped with a modern bath and change house, this elemental smell may not penetrate the camp, but it is generally within striking distance, nevertheless. At the less favored camps, it is more than liable to come out to meet you, as you enter a house, and around some of the rooming houses, there is danger of its standing guard and driving away the uninitiated and faint-hearted.

We are not casting any aspersion toward our coal miners; they probably bathe oftener than any other class of workingmen; but a smell is smell for all that.

Chickens as Gas Detectors

Experiments seem to prove that chickens are not suitable for use as detectors of gaseous atmospheres in mine-rescue work. In combating a mine fire at a colliery in the Raniganj coal field in India, a chicken was carried in by two members of the fire-fighting squad. On returning to the pit bottom the chicken was all right, but both men fell to the ground in a collapsed state.

Another instance of the use of chickens was at the rescue operations at the Kendwagih colliery, where it was noticed that the chickens were quite unaffected by the mine atmosphere while the men were knocked over.

One reason for the experiments with chickens is due to the fact that many mining men believe that mice and canaries are too delicate indicators of danger. Such authorities contend that the margin of safety with mice and canaries is too large, for these latter, when used as detectors, keel over at a time when men are still unaffected and can continue quite a while in their rescue operations.

What is desired is some animal or bird that is only slightly more susceptible to poisonous atmospheres than man. At the same time, of course, it must be remembered that in rescue work, the man is actively engaged in expending physical effort, while the animal is usually at rest.

Don't Destroy Your Records

The press dispatches from Houghton, Mich., of Mar. 4, reported that the books of the mining companies were brought into court to disprove miners' statements as to starvation earnings they received during the years 1908 and 1911.

The companies were thus able to exhibit to the court the original entries, down to the last penny, showing the actual earnings of all of the men who had testified, and the evidence thus presented, disproved most of the miners' contentions.

Here, then, is another illustration of the importance of preserving old records. Year by year, as the books of any company begin to accumulate, the temptation to destroy old files becomes more and more persistent and occasionally a good-sized bonfire follows. But, unfortunately, something more troublesome than musty files often rises up from the bonfire ashes.

The popular idea, that if a bank president or a corporation auditor testifies that the books of his firm were destroyed, he admits that he is trying to hide someone's guilt, is far from correct, in many instances, as some who read these lines could probably testify. But knowing a thing yourself and being able to convince others of the truth of your information, are quite different matters.

We recall a laughable but highly satisfactory turn to testimony being taken before an arbitration board, during a miners' strike, some years ago. The president of the miners' union had been ranting in quite approved manner about the terrible iniquities of the company stores in the district and the unreasonableness of expecting the men to do all of their trading in these stores, when competing merchants offered so much more for one's money.

This miner's president lived at one of the mining villages where there was one of these commissaries and some six or eight independent stores, so he surely spoke with full knowledge. Imagine the surprise of all present when counsel for the operators produced the books from the terrible company store in the very village where the miners' president lived, and proved that this very president was buying voluntarily from this "robbisary" and buying in such quantities that he must have depended upon it for most of his supplies.

Of course the miners' counsel was able to explain such conduct (to his own satisfaction at least). He stated that the goods handled by the company store were fresher than similar goods handled by competitive stores and his client, the miners' president, was able to stand the premium demanded.

Schools

This is an age of schools. No one nowadays who looks for success expects to get it without training his employees. We except mining men from this rule. They are imparting a knowledge of mine management, but they are only seeking to develop the men who are striving for first honors.

We were recently reviewing a book on the art of firing a boiler. Like all real mining men, we had not yet realized that there was a true art in heaving and spreading coal and raking the grate bars. But there is. When we begin to try to teach our employees how to perform their duties, we shall learn what a lot there is that we do not know about the fundamentals of our work and it will be hard indeed to tell who are most educated by the school, the teachers or the taught.

We have our miners, our car trimmers, our locomotive engineers, our dumpers, our shotfirers, our stationary engineers and our firemen to teach. Then there must be schools for our store clerks and office men. Have we realized that the sales forces of an insurance company, a cash-registry corporation or a telephone exchange has gone through a course to train them to please the public and help you with your problems?

Why do we take any kind of callow youth to sell groceries and let him stir up dissension by his indifference to customers and drive trade away by his uncleanly appearance? Why are we indifferent to his lack of knowledge as to values and the needs of the trade? Many a company has aroused all the women folk at their mines to open enmity because the store was not run as if their trade depended on the way in which their pleasures were met.

The time will come when our young miners will come from the village school primed with the facts of first aid and self-preservation and having at least a smattering of the rules of the art of mining. A half century ago, perhaps 25 per cent. of the people could neither read nor write. Ten years from today, everyone will have a certain amount of vocational training. What that time will bring forth in the way of efficiency, we do not dare to guess, but we shall look back then with surprise at the crude attempts at industry which now fill us with admiration.

Everywhere comes the cry, "It can't be done—these men are not bookkeepers, surveyors, track-layers or chemists." Thus systems, simple in character, requiring a week's study perhaps, from those who should carry them out are declared impossible, because the men who must perform them are not sufficiently trained, or lack the necessary desire for efficiency. When men are properly taught, they will themselves originate systems of procedure requiring more skill than we venture now to propose to them.

The Union and the Republic

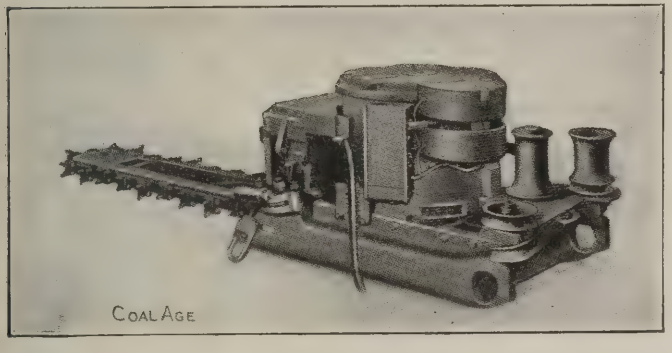
Our attitude toward the Miners' Union cannot justly be different from our attitude toward the government under which we live, for in one the laboring man is the only voter, in the other it is his vote which determines the issue. After all, there is little difference between the people represented in the labor unions and in Congress. To despair of the workingmen's councils is to question the safety and the future of the republic.

When we see the conservatism and justice of the masses voting as citizens, how can we doubt their essential fairness and honesty voting as members of a union? Logic and patience will assure industrial peace, just as those qualities will preserve the national existence free from internecine strife.

He who doubts that the union will ultimately realize its responsibility has lost his hold on our past history and the basic facts of our democratic government. By the exercise of industrial statesmanship, we shall at length arrive at a time when the unions will eject from their counsels, as they have largely from their leadership, those mere trouble-makers and mercenaries who threaten alike the operator and the union, and wreck at once the fortunes of the operator and the happiness of the operative.

By giving the labor leader a recognized position and the dignity which goes with it, we assure ourselves that he will respect his responsibilities and will work to advance sanity in labor agitation, honesty in the making of agreements and safety in mine operation.

There are parts of the country where already the union men are learning that to be tribunes of the people does not demand loud-mouthed oratory and class hatred, but qualities of restraint and character such as are demanded of those whose duty it is to direct the destiny of the nation. In such places the leaders go hand in hand with the operator in promoting the common good, and only part when their interests conflict, and then not in anger, but with the object of advancing their legitimate interests. A little reason and an infinity of patience will soon result in bringing union and operator into peaceful agreement.



Alternating-Current Coal Cutter

To meet the demand of operators located near transmission lines of large central power plants producing alternating current, a new alternating-current short-wall coal cutter has been placed upon the market by the Morgan-Gardner Electric Company.

The motor is very efficient, having great mechanical strength and ample overload capacity. The small number of parts assure continuous operation with practically no attention. This motor is exceptionally well ventilated. The star-delta control is used, which is the most simple, satisfactory control for induction motors of this capacity.

The stator can be quickly removed from the motor body. The stator core disks are waterproofed and riveted together under hydraulic pressure. The stator coils are form-wound and impregnated with a moisture- and oil-resisting compound that will stand a high degree of temperature. These coils are laid in open slots and easily accessible.

The rotor is fireproof, the bars being imbedded in a special moisture- and heat-resisting cement. The short-

A Short-Wall Coal Cutter Actuated by Alternating Current

circuiting rings are cast solid with the bars, leaving nothing on the rotor to work loose. The rotor shaft is exceptionally heavy with removable heat-treated chrome-nickel-steel pinion.

The three self-aligning ball bearings are of ample proportions to insure cool running and long life, the air gap is always uniform and the motor cannot strike the stator. These dirt-proof bearings are grease lubricated, eliminating all danger of oil trouble.

The construction of the rest of this machine is identical with the well known short-wall type of direct-current machine, embodying such features as single-reduction spur-gear drive to chain-drive sprocket, safety-break washer protecting feed-cable mechanism from overload, means for sumping without use of extra equipment. All parts are inclosed in a heavy rugged frame, yet easily accessible. The cutter arm is of cast steel and the cutting chains are for heavy duty and of single- or double-bit type.

A special feature is the simplicity and safety in handling these machines. A quick-acting positive clutch and the safety-break washer protect the feed cable from overload. The current is controlled by a simple knife switch within easy reach of the operator. By the drag-line control the operator can instantly start or stop the feed of the machine. All operations, unloading, sumping, cutting, loading and transportation are done by power.

A self-propelling steel truck with friction drive, reverse-drive gearing and removable automatic cable reel are used for transportation.

Saline County Mine Safety Association

The organization of the Saline County Mine Safety Association was perfected on Mar. 19, at a meeting held in the office of the O'Gara Coal Co., in Harrisburg. The following constitution and bylaws is given in full as an example for use by other similar organizations.

NAME—This organization shall be known as the Saline County Mine Safety Association.

OBJECT—The object of this association shall be, through its membership, to learn and to teach the most approved first-aid-to-the-injured and mine-rescue methods; to put this knowledge to practical use through organized teams and classes of instruction whenever occasion offers; to endeavor to increase the membership by getting others to take up the work; to bind closer together those who have taken training by holding frequent local meetings for study and practice, and annual state meetings with like associations for the purpose of comparison and inspiration; and to give to its members an opportunity to study mining, mine safety, first aid, etc., through coöperation with the State Rescue Commission, the Illinois Miners' and Mechanics' Institutes, the State Mining Board, and the United States Bureau of Mines.

CONSTITUTION

ARTICLE I—Section 1. All persons who have taken, or desire to take, the course prescribed for First Aid or Mine Rescue by the State Mine Rescue Commission, or who have been enrolled in the instruction classes of the Illinois Miners' and Mechanics' Institutes, are eligible for membership in this association.

ARTICLE II—Section 1. The officers of this association shall be a president, vice-president, secretary and treasurer, who shall be elected by a majority vote of the members present at the annual business meeting of the association.

Section 2. The government of this association shall be by a board of directors, who shall be elected in the same manner and at the same time as the officers. This board shall consist of sixteen men, of whom the four officers of the association shall be members ex-officio.

ARTICLE III—Section 1. The dues of this association shall be fixed by the by-laws.

ARTICLE IV—Section 1. The president shall preside at all meetings of the association and of the board of directors; shall sign all official documents and bills when satisfied of their correctness; shall appoint a custodian of the association's property; shall appoint a committee to audit the books semi-annually; shall appoint such first-aid and mine-rescue instructors and teachers in mining, as are needed; and shall at all times endeavor to build up the association and increase its usefulness. All appointments by the president shall be made subject to the advice and approval of the board of directors and of the coöperating state department.

Section 2. The vice-president shall, in the necessary absence of the president, assume all the duties and responsibilities of that officer.

Section 3. The secretary shall keep true minutes of all the transactions of the association; shall receive all admission fees, dues and donations; shall give a receipt for all money received, and shall keep a correct account of the same and turn all money over to the treasurer, taking his receipt for the same; and shall sign all bills approved for payment.

Section 4. The treasurer shall receive and care for all money of the association, and pay all bills when they are properly signed by the president and the secretary, taking a receipt for all money paid out; and shall keep a set of books showing all money received and paid out.

BY-LAWS

ARTICLE I—Section 1. The association shall meet at 7:00 o'clock the first Wednesday evening of each month except during June, July, August and September.

Section 2. Special meetings may be called at any time by the president.

Section 3. The officers shall be elected on the regular meeting night in the month of October, and this meeting shall be called the annual business meeting of the association.

ARTICLE II. The dues of the association shall be One Dollar per year, payable in advance.

ARTICLE III—Section 1. The order of business for the annual meeting, and for the meetings of the board of directors, shall be: 1. Roll call. 2. Reading of minutes. 3. Applications for membership. 4. Reports of officers and committees. 5. Communications. 6. Unfinished business. 7. New business. 8. Election of officers. 9. Adjournment.

Section 2. Roberts' Rules of Order shall apply at all business meetings.

Following the adoption of the constitution, committees were appointed to perfect the arrangements for the first aid contest to be held at Harrisburg on May 2. The following committees were appointed: Invitation, Wm. Johnson, chairman; Finance, Ed. Joyce, chairman; Grounds, D. B. McGeehee, chairman; Prizes, Wm. Johnson, chairman; Entertainment, O. M. Karraker, chairman; Programme, Oscar Cartlidge, chairman.

During the evening the meeting was addressed by Oscar Cartlidge, superintendent of the Illinois State Mine Rescue Commission, on the purposes and aims of the first-aid movement, it being the intention of the local association to cooperate with the State Commission in this work. He promised the hearty support of the commission under his management, and is arranging to have periodical examinations of the students in first-aid work, for the purpose of granting certificates to those men who demonstrate their proficiency in the work. R. Y. Williams, director of the Illinois Miners' and Mechanics' Institutes, addressed the meeting on the purposes and aims of these institutes, and introduced the instructor, E. C. Lee, who is in charge of the schools just opened in Harrisburg and Herrin under the direction of the institutes. The latter discussed in detail the scope of the work to be covered by the schools, and the method of instruction, extending an invitation to all present to join the classes.

Referendum of United Mine Workers

In an official circular, President John P. White, Vice-President Frank J. Hayes and Secretary-Treasurer William Green, recount the unsuccessful attempts of the scale committee to secure an agreement with the operators at the Philadelphia meeting, which commenced Feb. 10, and also at the Chicago meeting, which opened session Mar. 17. They say that the policy committee then met to define the course to be pursued and "deemed it unwise to engage in a national strike at this time for the enforcement of" their "demands."

They call for a referendum vote on Apr. 14, authorizing:

The representatives of the United Mine Workers of America in subdistricts, districts and groups of districts to negotiate * * * * wage agreements with coal operators * * * * who will agree to the prices now being paid under the present contract for pick and machine mining, day labor, yardage and dead work or the equivalent of the tonnage and mining prices where any district, subdistrict or groups of districts, either by reason of an act of the legislature or by agreement may change their method of mining from screen coal to mine run.

The proposal to be submitted to referendum permits the local determination of inequalities as to prices and conditions, *requires* the continuance at work of the men pending a settlement of these minor matters where the operators agree to the prices, hours of labor and conditions of employment now in effect, *permits* the working of the men where the scale is being changed from a screen-coal to a mine-run basis while a settlement is being reached and provides that the contracts when made shall be in force for a period of two years, to end Mar. 31, 1916.

The circular states:

The nonunion operators desire a strike in the organized fields so that they can obtain contracts. We were reliably informed that representatives of the nonunion operators of Kentucky, West Virginia, Pennsylvania and elsewhere, were in both Philadelphia and Chicago while the joint conferences were in session, doing all within their power to bring about a disagreement and a strike. And so, in view of the slack work generally, we are unwilling to play into the hands of the unorganized operations by going on strike, throwing the union mines idle and thus allowing the nonunion fields to fill the markets with their coal.

The reports of the election must be sent to the international secretary not later than Tuesday, Apr. 21.

The joint scale committee of miners and operators of central Pennsylvania, which was in session for two weeks in Philadelphia trying to make a scale, adjourned on Saturday, Apr. 5, and will meet again after the decision by referendum is reached. The operators were unwilling to continue in session with the miners because the latter were not empowered to make a final settlement. There is some hope that the meeting will be able to reconvene about Apr. 24. Meanwhile the mines will continue to work as orders are received, but as business is not brisk, there is no prospect of steady work. The miners and operators in central Pennsylvania agree that the miners should have the same tonnage rate as in the two years past. The miners, however, want car pushing abolished. This the operators are unwilling to concede without a reduction in the contract rate.

Anthracite Section of American Institute of Mining Engineers

At a meeting of the anthracite section of the American Institute of Mining Engineers, R. V. Norris, of Wilkes Barre, was elected president, and four vice-presidents were also elected, each of whom is to have general direction of the section's activities in one of the coal fields. W. J. Richards, vice-president and general manager of the Philadelphia & Reading Coal & Iron Co., is to have general direction for the Southern coal field, Edwin Ludlow, vice-president and general manager of the Lehigh Coal & Navigation Co., for the Middle coal field, Arthur Storrs, mining and consulting engineer, for the Lackawanna Valley, and C. F. Huber, vice-president and general manager of the Lehigh & Wilkes Barre Coal Co., for the Wyoming Valley. Charles Enzian, mining engineer and the Government representative of the United States Bureau of Mines in the anthracite fields, was elected secretary-treasurer.

An executive committee was formed, consisting of Frank Hill, a coal operator, R. A. Quin, vice-president and general manager of the Susquehanna Coal Co., R. J. Foster, vice-president International Correspondence Schools, A. B. Jessup, vice-president and general manager of the G. B. Markle Co., D. Bunting, chief engineer of the Lehigh & Wilkes Barre Coal Co., and J. M. Humphrey, mining engineer of the Lehigh Valley Coal Co.

A request from the president of State College was read at this meeting, asking that three delegates be appointed by the society to vote at the annual election for trustee.

Douglas Bunting was elected chairman of the committee to select the subject for discussion at the next meeting. The committee selected "The Limits of Mining under Heavy Wash," and J. M. Humphrey will also read a special paper on strippings. The meeting will be held on Saturday evening, May 9, at 7:30 in the Auditorium of the Lehigh & Wilkes-Barre office building at Wilkes-Barre, Pa.

Discussion By Readers

Straightforwardness in Mine Inspection

I was much impressed with the frank and manly statements quoted in the brief review of Mine Inspector McGregor's report, COAL AGE, Mar. 21, p. 474. I think these brief statements are the clearest and most direct that I have ever observed as coming from a mine inspector.

While commending Mr. McGregor on the straightforward, frank manner in which he states facts and truths that every mining man knows but that few have the courage to assert, I must also give COAL AGE due credit for giving to these statements a wider publicity than they would otherwise have and which they truly deserve. By this means, the statements are brought home to the men who should profit most by the opinions so frankly stated. There is too often a tendency to restrict the publication of frank and honest statements relating to actual facts and existing conditions. These must be known and appreciated in order to properly stimulate the many worthy efforts that are now being made on such an extended scale to increase safety in the mines.

It is a matter of common observation that mine inspectors' reports are too often stereotyped forms, consisting of printed blanks filled in with figures and supplemented by perfunctory statements that reveal little or nothing of the real knowledge and conviction of the man making the report. The public have a right to know the honest, candid opinions and conclusions of the men entrusted with the work of inspection and who are best qualified to place the blame for existing dangerous conditions or accidents where it properly belongs. Such candid reports would represent a consensus of opinions of qualified men that could be used as a basis on which to devise means for greater safety.

The Court of Public Opinion is far more powerful than the law itself to eradicate evil, lessen danger and reduce the accident list. The "hush" policy is wrong in principle, as it obstructs the formation of correct public opinion. Only by a frank, open statement of facts, in the technical press, can the misrepresentation and exaggerated statements of the secular journals be corrected. It is such misstatements and wrong viewpoints that often go far toward undoing the work that has been accomplished in the interest of safety. Every state mine official is the paid servant of the people, and loyalty to the trust confided to him should always compel a frank, conscientious statement of his honest convictions.

That the general reticence of mine inspectors is always the result of restrictions placed upon them by their superiors in state office is hardly conceivable. It has been my good fortune to know intimately a number of miners and mining men who have risen from the ranks to the position of mine inspector. While these men, in a subordinate position, were frank and outspoken in reference to the existence of a wrong or dangerous condition, in most cases they have shut up like clams when they have risen to the position of mine inspector. Let us hope that this mistaken policy will be abandoned by many in the future and that more will follow the path dictated by their honest convictions.

Houston, Penn.

The Certificate Law

Letter No. 26—I have been pleased to note that the question of an interstate certificate law, which I suggested for consideration in COAL AGE, some time since, has been discussed so thoroughly. The discussion has proved most interesting, and I am pleased to note that the majority of the writers seem to favor the proposed interchange of certificates between states.

I cannot agree with the suggestion that the practice would be "harmful;" on the contrary, I consider it would be an inspiring incentive to every man desiring to extend his knowledge and experience beyond the narrow limits to which he is confined in his own state. As well might a sea captain be required to have a navigator's license to sail every sea and navigate every coast line as for a capable mine foreman holding a state certificate, to be required to pass examination before he can hold the same position in another state.

In respect to physical conditions in coal mining, state lines have no existence; and conditions are more or less alike in the various coal-mining districts. Flat and pitching seams, gaseous and nongaseous mines, are quite generally distributed; and methods of working, mining machinery and equipment, and mining laws are very much the same everywhere. The various nationalities of the miners present the same difficulties in one place as in another.

If these facts are generally conceded there would seem to be no tangible reason why coal-mining states should hesitate to make provision for an interstate certificate law. Not only would this open a wider field to students of mining, as suggested; but operators would benefit by such a law, since it would afford them a wider territory from which to select men of intelligence and ability.

The province of Alberta, Canada, has recently passed a law, authorizing the issuing of a certificate of competency to all applicants who hold a similar certificate granted in another country, provided the examining board in Alberta certifies that the standard of training and examination required by the foreign certificate is equivalent to that required in their own province. (COAL AGE, Apr. 4, p. 584.) Certificates of competency granted in England are good in all her territorial possessions, notwithstanding her supposed insularism.

A little reflection forces upon us the conviction that the restrictions and limitations of our mining laws are, in this respect, an obstacle to progress and the gaining of wider experience. Men who have proved their ability and success in coal mining and who already possess a certificate of competency of the required standard should

not be classed in the same category with the student whose experience is yet to be gained and whose ability is yet to be proved.

The spirit of a law making state-line limitations possible, in the matter of the recognition of industrial experience and ability, is, to say the least, unreasonable and un-American. It is to be hoped that this discussion will be the means of enlisting the interest of lawmakers and that an enactment may be secured that will broaden the field to mining men.

Working Coal under Watery Strata

Letter No. 6—The inquiry of George McPhail, COAL AGE, Jan. 3, p. 30, in regard to working a coal seam under a watery strata, and the later discussion by readers, has been of more than ordinary interest to me. I have just completed the sinking of a shaft here at Lehigh, Mont., under conditions very similar to those described by Mr. McPhail, with the exception that the coal seam here is 13 ft. in thickness, instead of 3 or 4 ft., as he states.

The information given regarding the geological cross-section of the country, and which would be of great assistance in intelligently answering this inquiry, as remarked by the editor at the time, was lacking. It would be feasible to assume that the shafts to be sunk are located in a basin, at or near the bottom of a synclinal trough. Taking these to be the existing conditions, geologically, I offer the following as my opinion and answer to the several queries submitted.

I believe that if the sandstone is broken, large quantities of water would flow into the mine, as the resulting caves would expose a much greater surface through which the water would find an easy channel into the workings. I also believe that a coal seam or mine of this kind would encounter large inflows of water wherever any displacement has occurred in the overlying strata, producing faults or large joints, which frequently cut across the bedding planes of coal seams. The inflow would be greater or less than the inflow into the shaft, according to the relative position of the break with respect to the shaft, the porosity and fissures in the sandstone. As will be noted from the statement of Mr. McPhail, the shaft did not affect the supply of water from the drillhole located only 50 ft. away. It seems evident that the whole of the formation of water-bearing sandstone, in this case, is practically one large reservoir, which will have to be drained in order to reduce the inflow of water into the mine, and I am of the opinion that, as the head of water in this basin is lowered, there will be a relative reduction in the inflow of water into the shaft and workings.

In answer to the second question, I consider that, in a mine located under the conditions described, the management should make arrangements and be prepared to handle large inflows of water, in case of emergency. Large sumps should be provided and equipped with uptodate pumping machinery. A good, efficient pumping system I always consider a valuable asset and investment for any company operating under these conditions.

Replying to the third question, I am of the opinion that the hoisting shaft, which is to be sunk, will encounter just as large a quantity of water as the air shaft sunk previously and possibly more if it has a larger area, unless the water has been drained in the meantime, in this basin, which is not probable, as the main hoisting shaft is generally sunk as soon as possible, so that it can be used in the development of the mine and for a second opening and ventilating purposes.

In reference to leaving about 50 per cent. of the coal in place, in order to prevent breaking the sandrock, I believe that a system of working could be adopted, in a thin seam of coal 3 or 4 ft. thick, that would make it unnecessary to lose any large percentage of the coal.

I consider that the safest method of working to adopt would be to open up the mine on a pillar-and-stall system, and then systematically flush the excavated area. In a thin seam of this kind there would be a large amount of material available for stowing in the workings, as the haulageways, roadways and airways would have to be brushed to a sufficient height, say 7 ft. This would produce quite a large amount of material and reduce in proportion the amount of material required to flush the workings. This system, when practicable, is the safest method to install that I know of, and is being used with success in quite a large number of mining districts today.

On the Continent, in Upper Silesia, over a hundred collieries have installed the hydraulic-packing or flushing system, in seams varying from 4 to 40 ft. in thickness, and have reduced the subsidence, which formerly varied from 30 to 70 per cent. down to a range of from 0.3 to 7.8 per cent. of the total thickness of the seams. In Essen, Germany, the Krupp firm is successfully extracting, from underneath their railway works, railways and large public buildings, 8 seams of coal, varying from 20 in. to 5½ ft., in thickness. They are enabled to do this with impunity, owing to the completeness with which the workings are filled with flushed material. Another method of working I would suggest, is to open up the workings on a pillar-and-stall, panel system, the entire panel to be surrounded by substantial pillars, which should have as few openings as practically possible and a minimum area. When the stalls are completed, in a panel, all the pillars should be withdrawn as rapidly as possible, precautions being taken to have good permanent stoppings built in all openings possible, surrounding the excavated area; and preparations made, in openings necessary for transportation and ventilation, so that in case of an inflow of water they may be quickly closed, thereby sealing up the excavated territory.

By experimenting with one or two panels of this kind, the action of the roof, and the effect it would have on the watery zone overlying the seam, would be practically demonstrated to the management, without their leaving in a large percentage of the coal seam. Then, if the expected or unexpected happened, they would be in a position to combat it successfully. They would also be prepared to adopt a system that would be suitable to the conditions which presented themselves. However, in conclusion I wish to state that the successful working of any coal property where adverse conditions present themselves will depend to a great extent upon the practical knowledge and judgment of the officials in charge.

J. W. POWELL, Supt.,
The Cottonwood Coal Co.

Windham, Mont.

Standardization of Mine-Track Gages

I noted with interest the request for a general discussion of the question of the standardization of track gages in mine haulage, COAL AGE, Mar. 21, p. 494. This is a many-sided question. It would be a simple matter to standardize track gages in mines, provided all coal seams were of the same thickness and other conditions relating to roof, coal and floor and the area to be worked were the same in all mines.

It is a well known fact that conditions in mines must largely govern the adoption of a fixed track gage. In the working of a 5-ft. seam, it would not be practicable to use the same track gage that would be adopted for similar conditions in a 7-ft. seam. In each case, the mine cars are built in proportions that are adapted to the special requirements, with a view to making the work of moving the cars as easy as possible for both men and animals. For this reason, in a 5-ft. vein, the track gage may vary, under ordinary conditions, from 18 to 36 in.; while, in a 7-ft. vein, a track gage varying from 36 to 44 in. would probably be used.

There are, besides, other conditions common to mining that determine the proper track gage. For instance, a tender roof would hardly permit the use of a 40-in. gage, even in a 7-ft. seam of coal. To reduce the cost of maintaining roadways they must be driven narrow, under a tender roof. Then, as the mining law generally requires a sufficient clearance for men and animals at the side of the track, it is necessary to use a comparatively narrow gage. At the same time, under these conditions, due regard must be had for the proper proportionment of the cars.

In general, in the operation of a large mine covering a wide area and requiring a large daily output of coal, the capacity of the mine car is an important factor. While, in a large number of mines, cars having a capacity of from 35 to 45 bu. are in use, in other mines this capacity will often have to be increased to 50 and 60 bu., in order to meet the requirements of a large daily output, especially in mines having an extended area of workings. Cars having so large a capacity require track gages varying from 44 to 48 in.

When considering the question of standardization of mine-track gages, therefore, it is necessary to take into account all of these conditions and many others that are of equal importance with those mentioned.

Oliphant Furnace, Penn.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

The use of the "relative potential" value, in all calculations to determine the natural division of air between two or more airways, is one of the most important considerations in the saving of time and labor and avoiding unnecessary multiplicity of figures, which increases the opportunities for error and yields less accurate results. An example or two will serve to make this fact plain.

EXAMPLES IN NATURAL DIVISION

Example—An air current of 100,000 cu.ft. per min. is divided at the foot of the downcast shaft, between the following four air courses or splits, thereby providing two separate ventilation districts on each side of the shaft:

Split A,	8 × 12 ft., 6000 ft. long
Split B,	6 × 20 ft., 12,000 ft. long
Split C,	6 × 12 ft., 8000 ft. long
Split D,	4 × 6 ft., 1000 ft. long

All the splits are open to the free passage of the air, no regulators being used. (a) Find the natural division of the main air current or the quantity of air passing in each split. (b) What is the pressure due to this circulation? (c) What is the horsepower on the air?

Solution—(a) The first step is to calculate the relative pressure potential for each of the four air splits. The area, perimeter and length of each airway are as follows:

Split A,	$a = 96$ *sq.ft.*;	$o = 40$ *ft.*;	$l = 6{,}000$
Split B,	$a = 120$ *sq.ft.*;	$o = 52$ *ft.*;	$l = 12{,}000$
Split C,	$a = 72$ *sq.ft.*;	$o = 36$ *ft.*;	$l = 8{,}000$
Split D,	$a = 24$ *sq.ft.*;	$o = 20$ *ft.*;	$l = 1{,}000$

Instead of using these full values as when finding the true potential value of an airway, the lowest relative values for the areas, perimeters and lengths are used. These relative values are obtained by canceling the common factors in the areas, perimeters and lengths, separately, which gives

Split A,	$a = 4$;	$o = 10$;	$l = 6$
Split B,	$a = 5$;	$o = 13$;	$l = 12$
Split C,	$a = 3$;	$o = 9$;	$l = 8$
Split D,	$a = 1$;	$o = 5$,	$l = 1$

The relative split potentials are then found as follows:

Split A, $4\sqrt{\frac{4}{6 \times 10}} = 4\sqrt{\frac{1}{15}} = 4\sqrt{0.06666} = 0.258$

Split B, $5\sqrt{\frac{5}{12 \times 13}} = 5\sqrt{\frac{5}{156}} = 5\sqrt{0.03205} = 0.179$

Split C, $3\sqrt{\frac{3}{8 \times 9}} = 3\sqrt{\frac{1}{24}} = 3\sqrt{0.04166} = 0.204$

Split D, $1\sqrt{\frac{1}{1 \times 5}} = \sqrt{\frac{1}{5}} = \sqrt{0.2} = 0.447$

Sum of relative potentials..... 1.088

The Coal Age Pocket Book

Since the quantity of air passing in each split, in natural division is proportional to the corresponding potential, the quantity ratio is equal to the potential ratio, which is true also for the sum of the quantities and the sum of the potentials. Thus, the ratio of the quantity (q) passing in any split, to the total quantity (Q) in circulation, is equal to the ratio of the corresponding split pressure potential (X_p), to the sum of all the split potentials (ΣX_p).

$$\frac{q}{Q} = \frac{X_p}{\Sigma X_p}; \text{ which gives } q = \frac{X_p}{\Sigma X_p} Q$$

Therefore, substituting the relative potential values just found in this formula gives the following:

Split A, $q_a = \frac{0.258}{1.088} \times 100{,}000 = 23{,}710$ *cu.ft. per min.*

Split B, $q_b = \frac{0.179}{1.088} \times 100{,}000 = 16{,}450$ *cu.ft. per min.*

Split C, $q_c = \frac{0.204}{1.088} \times 100{,}000 = 18{,}750$ *cu.ft. per min.*

Split D, $q_d = \frac{0.447}{1.088} \times 100{,}000 = 41{,}090$ *cu.ft. per min.*

Total quantity..... 100,000 *cu.ft. per min.*

(b) Since the pressure is the same for all the splits, it can be calculated from any one of the given splits, by substituting the values for that split in the formula

$$p = \frac{k\,l\,o\,q^2}{a^3}$$

Thus, taking split A,

$$p = \frac{0.00000002 \times 6000 \times 40 \times 23{,}710^2}{96 \times 96 \times 96} = 3.05 \text{ } lb.\ per\ sq.ft.$$

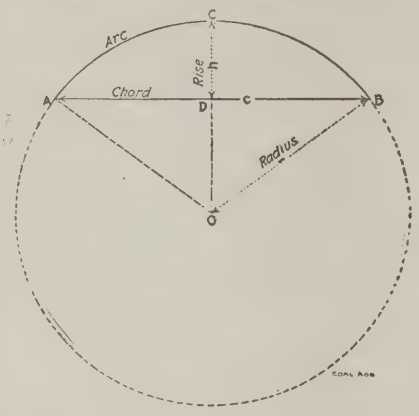
(c) The horsepower on the air in the main entry, or the horsepower producing this circulation is, then,

$$H = \frac{Q\,p}{33{,}000} = \frac{100{,}000 \times 3.05}{33{,}000} = 9.24 \text{ } hp.$$

General Split Potential—The potential value for the combined splits must be calculated from the total quantity of air in circulation and the resulting pressure, using the formula

$$X^3_u = \frac{Q^2}{p}; \text{ or } X_u = \sqrt[3]{\frac{Q^2}{p}}$$

Example—What is the general power potential for all the splits combined, in the example given above, where 100,000 cu.ft. of air was circulated under a pressure of 3.05 lb. per sq.ft.?



Solution—The general power potential for these combined splits is

Mine power potential, $X_u = \sqrt[3]{\frac{Q^2}{p}} = \sqrt[3]{\frac{100{,}000^2}{3.05}} = 1875$

Inquiries of General Interest

Study Question--The Circle

Referring to the inquiry in reference to finding the area of a segment of a circle when the length of the chord and the rise of the arc are known, COAL AGE, Mar. 21, p. 500, I wish to submit the following simple solution that does not entail the use of trionometry. The formula is taken from Des Ingenieurs Taschenbuch, 18th edition, Berlin, 1902, p. 34.

THE SEGMENT OF A CIRCLE

Referring to the accompanying figure, in which the length of the chord subtending the arc is c and its rise h, the radius of the circle being r, the length of the arc is first found by the formula.

$$arc = \sqrt{c^2 + 16/3\,(h^2)}$$

Then, making $c = 12$; $h = 3$, and substituting these values in the formula we have

$$arc = \sqrt{12^2 + 16/3\,(3^2)} = 13.86$$

The area of the sector $ACBO$ is next found by multiplying the length of the arc ACB by one-half the radius of the circle. The radius of the circle being the hypotenuse of the right triangle ODB, its length is found as follows:

$$r^2 = (c/2)^2 + (r - h)^2$$

$$r = \frac{(c/2)^2 + h^2}{2h} = \frac{6^2 + 3^2}{2 \times 3} = 7.5\ ft.$$

The area of the sector $ACBO$ is then $13.86 \times 7.5/2 = 51.975$ sq.ft. Subtracting from this the area of the triangle ABO, which is $c/2\ (r - h) = 6 \times 4.5 = 27$ sq.ft., the area of the segment $ACBD$ is $51.975 - 27 = 24.975$ sq.ft., approximately.

V. SRAJN,
Mining Engineer.

Hymera, Ind.

I noticed a request from "Reader," COAL AGE, Mar. 21, p. 500, for a formula for finding the area of a segment of a circle from the length of its chord and the rise of the arc, without the use of trigonometry. The following simple rule may be of use in the solution of this question:

RULE—*Add together one-fourth of the square of the chord and two-fifths of the square of the rise of the arc. Multiply the square root of this sum by four-thirds of the rise of the arc.*

Calling the chord subtending the arc c and the rise of the arc h, this rule is expressed by the formula:

$$area\ of\ segment = 4/3\ h\ \sqrt{c^2/4 + 2/5\ (h^2)}$$

Then substituting the values $c = 12$; $h = 3$,

$$area\ of\ segment = \frac{4 \times 3}{3}\sqrt{\frac{12^2}{4} + \frac{2}{5}(3^2)}$$

$$= 4\sqrt{\tfrac{144}{4} + \tfrac{18}{5}} = 4\sqrt{39.6} = 25.17\ sq.ft.$$

Cobalt, Canada. JOHN MCPHEE.

Both of the solutions given above obtain more or less approximate results. To show the degree of approximation that can be obtained by the solution, COAL AGE, Mar. 21, p. 500, we will calculate the successive values for h_1 h_2, h_3, etc., according to the method there explained, using Formula 3, for that purpose, which is

$$h_1 = r\ (1 - \sqrt{1 - h/2\,r})$$

In this formula, $r = 7.5$ ft. and $h = 3$ ft.; but the values h_1, h_2, h_3, etc., are each in turn substituted for h, to obtain the next succeeding value, as follows:

$$h_1 = 7.5\ (1 - \sqrt{1 - 3/15}) = 0.792$$

Again, substituting this value of h_1 for h, in the same formula, gives

$$h_2 = 7.5\ (1 - \sqrt{1 - 0.0792/15}) = 0.201$$

Likewise, substituting this value of h_2 for h, in the same formula, gives

$$h_3 = 7.5\ (1 - \sqrt{1 - 0.201/15}) = 0.0504$$

Similarly, substituting consecutively the values for h_3, h_4, etc., the following values are obtained: $h_4 = 0.01261$; $h_5 = 0.003154$, nearly; $h_6 = 0.0007885$, nearly.

The length of a subarc or unit division can be calculated from any one of these values and such unit length multiplied by the corresponding number of subdivisions, to obtain the length of the full arc ACB. It is evident that if the work is carefully performed, the greater the number of subdivisions, the closer the result will approximate the true length of arc.

In any case, the length of arc is calculated by the formula

$$arc = 2^{n+1}\sqrt{2\,r\,h_n}$$

Multiplying the length of the arc ACB, as thus calculated, by one-half the radius of the circle will give the area of the sector $ACBO$: and, finally, subtracting the area of the triangle ABO (27 sq.ft.) from the area of this sector, will give the required area of the segment $ACBD$.

The lengths of the arc $A\,C\,B$, as calculated from the respective values of h_3, h_4, h_5 and h_6, previously given, are as follows: 13.912; 13.918; 13.920; 13.920 ft., and the corresponding areas of the segment $ACBD$, as calculated in the manner previously described, are 25.17; 25.19; 25.20; 25.20 sq.ft. The last two values are, thus, practically identical and may be taken as being the closest possible approximation.

Examination Questions

Miscellaneous Questions

(Answered by Request)

Ques.—What is the total weight of an open tank 9 ft. long, 4 ft. wide and 2 ft. high, made of ¾-in. boiler plate; allowing 8 per cent. additional weight for the flanges and assuming that 1 sq.ft. of boiler plate 1 in. thick weighs 45 lb.?

Ans.—The perimeter of the tank, or the measurement around the sides and ends is 2 (9 + 4) = 26 ft. The superficial surface of the sides and ends is then 2 × 26 = 52 sq.ft. To this must be added the area of the bottom of the tank, 4 × 9 = 36 sq.ft.; making the entire superficial surface of the tank 52 + 36 = 88 sq.ft. For a ¾-in. boiler plate, the corresponding weight of the iron in the tank is ¾ (45 × 88) = 2970 lb. Allowing 8 per cent. additional weight for the flanges makes the total weight of this tank 2970 × 1.08 = 3207.6 lb.

Ques.—(a) The course of the main entry of a mine is N 17° W; what is the course of a cross-entry turned to the right of the main entry, at an angle of 90 deg.? (b) What is the course of the rooms turned off this cross-entry, at an angle of 67° 30′, to the right?

Ans.—(a) The course of the main entry lying in the northwest quadrant and the cross-entry being turned to the right, its course is 90 — 17 = N 73° E.

(b) The rooms being turned 67° 30′ to the right of the cross-entry, their course is found by adding this angle to the azimuth of the cross-entry, which gives for the azimuth of the rooms, 73° + 67° 30′ = 140° 30′. Since this azimuth lies in the southeast quadrant, the corresponding bearing or course of the rooms is 180° — 140° 30′ = S 39° 30′ E.

Ques.—Assuming a ventilating fan running at constant speed and having a constant manometric efficiency, in which case would this fan circulate the largest quantity of air: 1. When operating on four airways, each 4x5 ft. in section and 800 ft. long. 2. When operating on a single airway 8x10 ft. in section and 1600 ft. long?

Ans.—The four airways, 4x5 ft., 800 ft. long, have the same sectional area (80 sq.ft.) and the same rubbing surface (57,600 sq.ft.) as the single airway 8x10 ft., 1600 ft. long. The potentials of these airways and that of the circulation are, therefore, the same in each case; and the fan, running at the same speed, will have the same manometric efficiency and produce the same quantity of air, in each case.

Ques.—A mine sump is 62 ft. long, 11 ft. wide and 9 ft. deep and full of water. How long will it take a 6-in. pump to empty this sump, at a piston speed of 100 ft. per min., the efficiency of the pump being 80 per cent.?

Ans.—The sectional area of a 6-in. plunger or piston is 0.7854 × 6^2 = 28.2744 sq.in. At a speed of 100 ft per min., the piston displacement of this pump is 28.2744 × 100 ÷ 144 = 19.635 cu ft. per min. Assuming an efficiency of the water end of the pump as 80 per cent., the pump will discharge 19.635 × 0.80 = 15.708 cu.ft. of water per min.

The capacity of the sump is 62 × 11 × 9 = 6138 cu.ft. The time required for the pump to empty the sump is 6138 ÷ 15.708 = 390+ min., or 6 hr. 30 min.

Ques.—(a) Define the term "potential," as applied to electricity in mines. (b) Define the term "difference of potential," as applied to electricity. (c) Define the terms "low voltage," "medium voltage" and "high voltage," stating to what class of work each of these terms is applicable, for use in mines.

Ans.—(a) In electrical work, the term "potential" is commonly used as synonymous with voltage and refers to the *pressure* of the current, as measured by the voltage.

(b) The expression "difference of potential," in electricity, refers to the *drop of pressure* between two points of the circuit. This is referred to, also, as the *"line drop."* It is the loss due to the transmission of the current between two points, as, for example, from the generator to the machine to be operated.

(c) Where the conditions of the supply of electricity are such that the difference of potential between any two points in the circuit cannot exceed 300 volts, the Bituminous Mine Law of Pennsylvania (Art. II) would class the current as one of "low voltage." Where the conditions are such that the said difference of potential exceeds 300 volts, but cannot exceed 650 volts, the same law classes the current as one of "medium voltage." Where the conditions of supply are such that the difference of potential exceeds 650 volts, the current is classed by the same law, as one of "high voltage."

Owing to the danger of contact of men and animals with live wires, *low-voltage* currents are preferable in all mine work underground, except where it is necessary to reduce to a minimum the size of wire conductors or cost of copper, for the transmission of power to the working face. *Medium-voltage* currents are better adapted for the operation of most machinery on the surface, as, for example, air compressors, hoisting and haulage engines and fan motors. Medium voltage is also best adapted for transmission of electrical power underground; but, in all cases, conductors carrying such voltage should be insulated and otherwise safeguarded. *High-voltage* currents are chiefly used for long-distance transmission of power, on the surface and, in rare cases, underground.

In the transmission of electrical power, the size of wire or cost of copper is reduced to a minimum by the use of an alternating current of high voltage; but direct current is almost always employed for the operation of motors for haulage, coal cutting, hoisting or wherever a high-starting torque is required. In the use of electrical power, therefore, at a considerable distance from the generator, it is more economical to use a medium- or high-voltage, alternating current for transmission to the point where the power is required; and transform and "step down" this current, at that point, so as to obtain a direct current of low voltage for use in the machine.

Coal and Coke News

Washington, D. C.

The Committee on Mines and Mining in the House of Representatives has begun a new inquiry into certain phases of the Colorado strike situation by calling before it John D. Rockefeller, Jr., and questioning him concerning the Rockefeller interests in the Colorado region. Mr. Rockefeller in testifying on Monday, Apr. 6, said that he was one of his father's representatives in care of his investments in the Colorado Fuel & Iron Co., in which J. D. Rockefeller, Sr., held about 40 per cent. of the common and preferred stock and about 50 per cent. in all of the bonds.

Mr. Rockefeller, Jr., did not know much about the holdings of other stockholders but he described the relationship between L. M. Bowers and the Rockefeller interests by saying that "he came to us and asked us if we had any interests in which he could be of service in the West, and knowing him to be of great value as a business man we asked him to investigate some investments we had in the far West at the time. This he did. Then he said he was to live in Denver, and we were glad to have him care for our interests there. He was first treasurer of the company and afterward made chairman of the board and this was done by the board itself without any knowledge on our part. I mention this to show you that he has been retained by the board because his long continued relationship with the company has been of great value to the enterprise."

When asked whether he was a dummy director, Mr. Rockefeller said that his practice was to get the best men that could be had and then stand by them. He himself had rarely attended the directors' meetings. When questioned with respect to the labor conditions in Colorado he said he had been impressed with the extensive welfare work that had been done by the Colorado Fuel & Iron Co. and offered to file the correspondence with the concern during the time the trouble culminating in the recent strike was in progress.

Mr. Rockefeller rejected the idea that he had only a passing interest in the situation in Colorado and asserted that he thought Mr. Bowers was the best man to handle the situation. He had not gone to Colorado himself because he preferred, as previously stated, to leave practical details in the hands of skilled men who were capable of dealing thoroughly with them, holding such men responsible for the results actually secured.

The hearing is to be continued with other witnesses concerning the circumstances under which existing conditions in the mining regions developed.

Amendments to the Mining Law

Senator Walsh Chairman of the Committee on Mines and Mining has offered a bill amending section 2348 of the Revised Statutes so as to read as follows:

Sec. 2348. Any person, or any corporation organized under the laws of the United States, or of any state, or municipality, or municipal subdivision of any state, as above provided, who have opened and improved, or shall hereafter open and improve, any coal mine or mines upon the public lands, and shall be in actual possession of the same, shall be entitled to a preference right of entry under the preceding section, of the mines so opened and improved.

It is believed that this bill or one to the same general effect will be acted upon by the Committee.

Senator Walsh has also offered a bill for the amendment of section 2347, Revised Statutes so as to make it read as follows:

Sec. 2347. Every person above the age of twenty-one years, who is a citizen of the United States, or who has declared his intention to become such, or any corporation organized under the laws of the United States, or of any state, or municipality, or municipal subdivision of any state, shall, upon application to the register of the proper land office, have the right to enter, by legal subdivision, any quantity of vacant coal lands of the United States not otherwise appropriated or reserved by competent authority, not exceeding 1280 acres, upon payment to the receiver of not less than $10 per acre for such lands, where the same shall be situated more than fifteen miles from any completed railroad, and not less than $20 per acre for such lands as shall be within fifteen miles of such road.

In addition to this he proposes to change section 2350 so as to authorize only one entry by the same person or corporation.

Harrisburg, Penn.

Further testimony to show that additional competition in the transportation of anthracite coal from the Schuylkill region would not be commercially feasible was given on Mar. 31, by A. T. Dice, general manager and vice-president of the Philadelphia & Reading Ry. Co., at the resumption of hearings for the defense in the Government's anti-trust suit against the Reading system and other anthracite interests.

It was brought out that surveys made in 1906 showed the construction of a railroad across the Broad Top Mountain to supersede the Mahanoy Plane would cost $7,500,000. The same construction, if undertaken now, it was asserted, would involve an expenditure of $9,000,000.

The old question of the abandonment of the Schuylkill Canal was brought up by the Government attorneys who endeavored to obtain from Mr. Dice an admission that the canal had been "designedly abandoned." Mr. Dice said that he knew of no canal that is now commercially successful. The Reading, he said, discontinued the use of the Schuylkill Canal because, although actual transportation of coal via the canal might be cheaper than by rail, the difficulties of loading and unloading and the distance of the canal from the collieries and coal yards, more than compensated any advantage, and made the canal route, as a whole, the more costly.

The decline, and finally the almost total elimination of the Schuylkill Canal as a factor in the transportation of anthracite coal, were explained by Edwin F. Smith, formerly superintendent of that property, as being due solely to economic causes. Although he said the users of coal preferred to receive it by rail, and that this preference ended the canal's career, he denied that the canal ever had been competitive with the Reading Railway. Mr. Coudert at last brought his cross-examination of Mr. Smith to the point where the latter admitted that every one else might call it competition, but still he would not.

Although the Pennsylvania Railroad is not a party to the suit, Robert H. Large, general coal freight agent of that company, testified as a witness for the defense. He said it is not the policy of his company to enter into joint rates with other carriers along whose lines bituminous coal is produced. He defended the right of the company, in the absence of compulsion by the Interstate Commerce Commission to endeavor to conserve its bituminous trade. Joint rates on anthracite coal, he maintained, inured to the public benefit.

Admission that the Reading Coal & Iron Co. is favored above other shippers of anthracite by the Reading Railway in the matter of extension of credit for freight charges was made on Apr. 3, by W. G. White, comptroller of the railway company.

Mr. White conceded, under cross examination, that the Reading Coal & Iron Co., gave no bonds, a privilege extended to only one or two shippers. He could recall no others which were given credit to the extent of as much as $100,000 for 60 to 90 days. Mr. Coudert, counsel, for the Government, read into the records accounts of the railway company showing an indebtedness of recent years running as high as $1,500,000 on the part of the Coal and Iron Co.

PENNSYLVANIA

Anthracite

Duryea—Suit has been entered against the Pennsylvania Coal Co., by A. B. Brown, who asks $5000 damages to his property caused by mine water. He claims that in the year 1908 the coal company sunk a bore hole near his property and has since pumped out a large quantity of water which at times overflows a small water course and enters upon his property causing culm, refuse, etc., to be deposited thereon.

Locust Gap—In a fire at Alaska Shaft early on Apr. 1, Thomas Graham and William McCoy, fire bosses were badly burned. A large number of men formed a fire-fighting force. The blaze grew rapidly but was finally gotten under control.

Cranberry—The mine workers at the collieries of A. Pardee & Co. threatened, on Apr. 2, to strike unless about 40 of the men back in their union dues paid up within the next week. "Button" troubles have recently occurred at a number of the mines in this vicinity, but there have been no strikes to enforce payment of dues.

Bituminous

Charleroi—The Charleroi mine of the Carnegie Coal Co. resumed work Apr. 2 with approximately 500 men. This number will be increased as miners become available.

Washington—Despite the counsel of the Official Board of District No. 5 of the United Mine Workers there were on Apr. 3 over 20,000 mine workers idle in Washington County. Of these all but about 800 quit because they did not wish to continue work until the wage scale was decided.

Connellsville—A considerable section of the state road just south of Poplar Grove in Connellsville Township recently collapsed into an abandoned mine.

Butler—Because the Erie Coal & Coke Co. refused to accede to their demands for an eight hour day 250 miners employed at Ferris went on strike recently. This and other mines in the Hilliards district have been working under union scale and conditions except as to hours of labor for the past three years.

WEST VIRGINIA

Wheeling—Since the strike of the Ohio coal miners was declared a migration of foreigners from the idle fields has been in progress. It is believed that the majority of the foreigners in the 5th Ohio Sub-District will be gone by the last of the month if the strike is not settled by that time.

The effects of this coal strike are declared to be wide spread affecting many lines of business other than mines. The railroads are hard hit and a conservative figure by a railroad official is that a million dollars a month will only about approximate the loss to the roads. There is also the loss to the employees through slack work which is considerable.

Colliers—Thirteen demands are presented by the striking miners of the Pittsburgh & West Virginia Coal Co. for consideration by the Board of Arbitration which Governor Hatfield proposes to name. Among the most important of these are recognition of the Union and an eight-hour day.

KENTUCKY

Louisville—The conference of Western Kentucky coal operators and miners was brought to an abrupt conclusion by the operators' ultimatum that no concessions involving an increased cost of production would be considered. Further negotiations will be carried on through the Joint Scale Committee. Meanwhile the 6000 miners affected will continue working under the 1912 agreement.

Lexington—The College of Mining of the State University has announced details of its short course in coal mining, which started Apr. 1 and will continue to May 27. Instruction will be given in the following work: Study of different mining systems, laying out for mining, and methods for thin and thick, flat and pitching seams; blasting, covering various explosives and the evils of improper blasting; machine mining; supporting excavations, including the principles of timbering; ventilation, with a study of the different methods and of coursing, splitting and regulating the current; the use of anemometers, water gages and other mine equipment; and mine rescue work.

Madisonville—About 150 miners employed by the Kingdom Coal Co. went out on strike Mar. 31, on the refusal of the company to grant wage increases and other demands made by the men. This mine was recently unionized, as far as the greater number of the men were concerned. It is reported that a number of them were discharged for this reason, and that this is one of the causes of the strike.

OHIO

Bridgeport—The miners of Belmont and Jefferson counties, 15,000 of whom are on strike, are apparently preparing for a struggle which may last six months or longer. Thousands are seeking temporary employment to tide them over the strike period.

East Liverpool—The Island Run coal mine which has been operated for a number of years by the Tri-State Ry. Co. recently discontinued operations. This mine has been the main source of fuel for the street car company for a number of years and employed from 40 to 50 men working in two shifts of 8 hr. each.

Columbus—Figures have been prepared by a number of Hocking Valley and Pomeroy Bend operators showing the real difference in cost of mining under the screen system and the mine-run system. These figures will likely play an important part in the negotiations for the renewal of the mining scale after the question of the constitutionality of the mine-run law is decided. They show that under present conditions the cost of mining in the thin vein district of Pennsylvania would be $0.6464, and in the thick vein district, $0.5611. In the meantime miners are trying to show that $0.71 3-7 would be an equitable basis for coal mined in the Hocking Valley, No. 8, and Cambridge fields of Ohio. On a machine mining basis the thin vein district of Pennsylvania would pay $0.4461 for cutting, drilling, timbering and loading and the rate in the thick vein district would be $0.3892. The rates which are being discussed in the Hocking Valley are $0.4928; in No. 8, $0.4517, and in Cambridge, $0.4140. These figures tend to show that Ohio is being discriminated against in many ways.

Coshocton—Harry Daly recently made a discovery of a four-foot bed of cannel coal on the Stockum farm located about two miles east of Coshocton. Arrangements are being made to open a mine in the territory.

INDIANA

Indianapolis—A circular sent out from the International Headquarters at Indianapolis and made public Apr. 3, calls for a referendum vote on Apr. 14 upon the decision of the miners' representatives at the conference recently held in Chicago to withdraw wage demands and recommending that such questions as working conditions which the miners feel are in need of adjustment should be taken up with operators locally, the miners meantime to remain at work. If this decision is ratified it will mean industrial peace, if not, a more or less extended strike.

Terre Haute—Mine workers of district No. 11 met here Apr. 6, as an adjourned session of the biennial convention, to decide on the demands of miners, to be presented to a joint convention of miners and operators Apr. 9. There will be no formal suspension of work in the mines.

Brazil—At a meeting of the joint boards of operators and miners in the block coal fields, it was agreed to work the mines pending the settlement of wage and other differences. The operators are reported to have considerable coal on hand.

Sullivan—A suit to test the question of whether a landowner conveys oil and gas rights when he sells the coal under his land has been filed in the Circuit Court here by the Sullivan Gas & Oil Co. which has leased land, to drill for oil and gas but owners of the coal under the land have also begun drilling for oil.

Vincennes—The Indian Creek Coal Mining Co., operating the largest mine in Indiana, claims the hoisting record of the state, having in eight hours hauled to the surface 3104 tons, beating the mine's previous record by one ton.

ILLINOIS

Harrisburg—The route for the Miners' Examining Board of Illinois for the month of April is as follows: Spring Valley, Apr. 2; Canton, Apr. 3; Peoria, Apr. 4; Danville, Apr. 9; Pana, Apr. 14; Springfield, Apr. 15 and 16; Staunton, Apr. 17; Breese, Apr. 23; Belleville, Apr. 24; Eldorado, Apr. 26; Duquoin, Apr. 29; Herrin, Apr. 30.

Ottawa—Twelve hundred men are idle as a result of closing down the coal mines at La Salle, Peru, Oglesby, Jonesville, and Cedar Point. This shut down was caused by an over-stocked market, many big consumers fearing a strike having stored many tons of coal.

Peoria—The Illinois coal operators on Apr. 3 refused to grant the demands made by the miners and presented a counter-petition to the latter containing clauses which not only lower the present scale of wages, but which provide for easier working conditions as a means of decreasing the cost of production.

Chicago—Five hundred English, Welsh, Irish and Scotch miners who had been employed for some time in Illinois and Indiana coal fields left Chicago Apr. 2 on a special train for Halifax, Nova Scotia, where they will embark for their old homes. They are taking advantage of a shut down in the mines to visit relatives across the sea.

MISSOURI

Midway—A 14-ft. bed of coal was recently discovered on the Newlin lease of the American Zinc, Lead & Smelting Co. The coal was first encountered at a depth of 28 ft. and continued to a depth of 42 ft. It is said to be one of the biggest deposits ever found in the Joplin district.

OKLAHOMA

Coalgate—Old No. 3 mine recently made a record by hoisting 819 tons of coal in one day. This is the most that has been taken out of that mine in years. Long ago, however, it had a record of over 1000 tons.

TEXAS

Wichita Falls—It is planned to have a demonstration in this city on Apr. 21 protesting against the treatment given "Mother Jones" during the Colorado coal strike. It is affirmed that 10,000 or more men from the north of Texas and Oklahoma will be in town for this occasion.

MONTANA

Red Lodge—The Northwestern Improvement Co. has made arrangements to proceed with the work of developing the big body of coal under the west bench, and active operations will be commenced in June. This new field will be developed by shafting and tunneling, and beds Nos. 2 and 3 will be tapped. It is anticipated that development of the mine, and placing it in a position for production, will probably consume a period of about three years.

FOREIGN NEWS

London, England—On Apr. 2 all of the coal miners in Yorkshire, numbering 17,000, had left the mines when the last of the notices to quit work had expired. The men demand the introduction of a minimum wage scale. Stocks of coal at the pitheads are only sufficient to last about one week, at the expiration of which time those industries depending on Yorkshire collieries for fuel will be seriously hampered.

PERSONALS

Thomas L. Lewis recently stated unequivocally that he would not again be a candidate for any office in the United Mine Workers of America. He would not give any explanation for his decision.

Roger Martin, superintendent of the Vulcan Coal Co. recently returned home from the Hospital in Roanoke, Va., where he underwent an operation for an abscess in the side. He is now able to attend to his work.

E. B. Coolidge, who has been coal and coke agent for the Wheeling & Lake Erie R.R. Co. has been transferred to Chicago with the position of general western agent. His former headquarters were at Cleveland.

B. F. Robertson, for many years connected with the mercantile department of the Consolidation Coal Co., and lately general manager of stores, for that concern has resigned. He has not announced his plans for the future.

Joseph Yannis, vice-president of the United Mine Workers District No. 1, was recently held up by two masked highwaymen near his home in Wilkes-Barre and robbed. The highwaymen, however, only secured $11 in cash and a gold watch.

I. P. Mullen and E. L. Halbert, superintendent and mine foreman at the Royal works of W. J. Rainey, were recently arrested on charges of violating a mine law which specifies that bore holes shall be kept 3 ft. ahead of the coal in narrow mine workings.

Gordon B. Late, recently purchased the entire interest of the Irvington-Late Coal Co. and will conduct the business under the name of the Gordon B. Late Coal Co. This firm now has 800 acres of Kittanning coal located on the Hardman branch of the Baltimore & Ohio R.R. in Preston County, W. Va.

Arthur Nealee, of Pittsburgh, will be general manager and superintendent for the recently organized Montour Coal Co. which has leased what are known as the Illinois Colliery Co. mines located at Springfield, Auburn, Virden, and Girard in Illinois. Provided the wage question is settled satisfactorily these mines will be operated at an early date.

Matt. Yurkonis was recently granted a verdict in the Brooklyn Federal Court of New York for $50,000 against the Delaware, Lackawanna & Western R.R. Co. for personal injuries received on July 6, 1911. His injuries were received in a combined explosion of gas and powder in a mine at Luzerne, Penn. This is one of the largest verdicts ever rendered a miner for personal injuries.

Edward Devoy, one of the best known coal men in the Middle West, announced his retirement as president of the Devoy & Kuhn Coal & Coke Co. on Apr. 1, to engage in business for himself, under his own name, with offices in the Equitable Building, St. Louis. Mr. Devoy organized the Devoy & Feurborn Coal Co. in 1885, but was active in coal trade circles for many years previous to that. That company was succeeded by Devoy & Kuhn.

RECENT COAL AND COKE PATENTS

Boiler Cleaner. E. H. Reiter, Elgin, Ill. 1,085,357, Jan. 27, 1914. Filed Nov. 20, 1912. Serial No. 732,526.

Derrick for Mines. J. E. Jones, Carneyville, Wyo. 1,085,208, Jan. 27, 1914. Filed Jan. 29, 1913. Serial No. 745,017.

Gas Producer. P. G. Schmidt, Olympia, Wash. 1,086,229 Feb. 10, 1914. Filed Feb. 15, 1913. Serial No. 748,757.

Mechanical Stoker. G. B. Rait, Minneapolis, Minn. 1,085,630, Feb. 3, 1914. Filed May 15, 1912. Serial No. 697,428.

Automatic Boiler Cleaner. A. A. Olson, Riverside, Ill. 1,086,307, Feb. 3, 1914. Filed Nov. 15, 1912. Serial No. 731,471.

Coal Handling Apparatus. F. F. Joseph, Chicago, Ill. 1,086,536, Feb. 10, 1914. Filed Jan. 6, 1913. Serial No. 740,271.

Fuel Saver. J. T. McKee, St. Johns, New Brunswick, Can. 1,086,834, Feb. 10, 1914. Filed Dec. 23, 1912. Serial No. 738,342.

Steam Boiler Furnace. G. S. Gallagher, New York, N. Y. 1,085,859, Feb. 3, 1914. Filed Aug. 13, 1910. Serial No. 577,006.

Stoker for Underfeed Furnace Grates. F. E. Davis, Morgan Park, Ill. 1,085,248, Jan. 27, 1914. Filed Sept. 4, 1912. Serial No. 718,545.

Emergency Plug for Boiler Tubes. A. T. Anderson, Camden, N. J. 1,085,519, Jan. 27, 1914. Filed Feb. 10, 1913. Serial No. 747,490.

Safety Lock for Self-Dumping Mine Cages. W. J. Phelan, New Salem, Penn. 1,085,297, Jan. 27, 1914. Filed Apr. 12, 1913. Serial No. 760,734.

Process of Treating Soft or Bituminous Coal and the Like. W. A. Ayres, Hazleton, Penn. 1,086,503, Feb. 10, 1914. Filed Apr. 17, 1913. Serial No. 761,822.

Apparatus for Treating Soft or Bituminous Coal for the Separation of Slate Therefrom. W. A. Ayres, Hazleton, Penn. 1,086,502, Feb. 10, 1914. Filed Apr. 17, 1913. Serial No. 761,821.

Coal Breaker and Cleaner. G. W. Borton and J. L. Hiller, assignors to Pennsylvania Crusher Co., Philadelphia, Penn. 1,086,129, Feb. 3, 1914. Filed May 12, 1908. Serial No. 432,488.

CONSTRUCTION NEWS

Whitesburg, Ky.—Representatives of the Slemp Consolidated Coal Co. recently announced that a million dollar coal operation would be started near Craftville.

Springfield, Ill.—The Cora Coal Co. recently placed a contract for the erection of a new tipple to take the place of the one recently destroyed by fire at their mine near this city.

Benton, Ill.—A large new mine is to be opened on the outskirts of Benton during the coming summer by the Middle Fork Mining Co. This firm is incorporated for $200,000, and owns 1660 acres of coal land east of the city.

Meyersdale, Penn.—The mining plants at Jerome and Boswell, owned by the United Coal Co. interests, will be improved and other ventures started after the receivership of the owning company, the American Water Works Co., has been concluded.

Sturgis, Ky.—The West Kentucky Coal Co. has let to the Alloway Lumber Co. the contract for the construction of 10 new houses at its No. 1 mine and 15 houses at No. 9. The lumber company has placed the material on the ground, and work will shortly begin on the new houses.

Hazard, Ky.—The Hazardtown Coal Co. recently organized with a capital of $100,000 will begin work Apr. 10 on a first class mining plant immediately below Hazard where it will develop 1000 acres of choice coal lands. W. M. Jones, of Barbourville, Ky., will be manager of the new operations.

Barbourville, Ky.—A railroad surveying crew has been working between this place and Manchester, Clay County, Ky., for several weeks, and it is understood that the plan is to extend the proposed Cumberland Northern R.R. from Barbourville to Manchester, the company having already acquired a right of way.

Buffalo, N. Y.—The Buffalo By-Product Coke Co., organized in New York some months ago, has broken ground for a plant near the Lackawanna Steel Co.'s property. The gas will be sold to the Lackawanna company and the coke will be handled by M. A. Hanna & Co., of Cleveland, which is interested in the Buffalo Union Furnace Co.

Chattanooga, Tenn.—The Durham Coal & Iron Co. plans to construct by-product coke ovens in blocks of 30 to 60, with a view to future additions. These will consume about 800 tons of slack coal daily, and 5,000,000 cu.ft. of gas will be sold. The initial expenditure will be approximately $1,000,000.

Penny, Ky.—The Long Fork Coal Co. will begin by Apr. 15, it is announced, a mammoth coal operation near Penny on Long Fork Creek to be reached by a new five mile branch of the Baltimore & Ohio R.R. At least seven openings will be made. The building of a good sized industrial city will be begun at once. Eight to ten million dollars will be expended in the work.

Whitesburg, Ky.—Three coal operations are to be started within a short time at the mouth of Boone's Fork. The Roberta Coal Co. contemplates an extensive plant a short distance up Boone's Fork, where it will expend a large sum to establish a first-class plant. At Mater, at the mouth of Boone's Fork, the Boone's Fork Coal Co. is now making preliminary surveys preparatory to starting building operations at which 500 men will be put to work. Following this the Consolidated Coal Co., one mile below the mouth of Millstone Creek, will begin operations shortly on another big operation.

NEW INCORPORATIONS

Mount Vernon, Ohio—The Eastern Kentucky Coal Co. has increased its capital stock from $1000 to $500,000.

Seattle, Wash.—The Beacon Coal Mines Co. of Seattle has been organized with a capital of $1,000,000. The incorporators are A. L. Knouse, V. C. Brown, and John F. Dore.

Middleport, Ohio—The River View Coal & Mining Co. has been organized with a capital of $5000. The incorporators are W. A. Brown, Emil Sauer, Laura Brown, W. L. Engler and Laura Engler.

Knoxville, Tenn.—The Royal Coal & Coke Co. has amended its name to the Royal Consolidated Coal Co., and increased its capital from $100,000 to $300,000. The incorporators are H. S. Pless, W. A. Pless, J. W. Goons, G. A. Atchley, and Ben. A. Morton.

Springfield, Ill.—The Montour Coal Co. has been organized with a capital of $50,000 to manufacture, sell, and ship coal and other minerals, also, manufacture and sell by-products thereof. The incorporators are Wm. L. Patton, Henry L. Patton, and H. R. Hall.

Fairmount, W. Va.—The Fairmount-Lincoln Coal Co. has been organized for the purpose of mining coal, with a capital stock of $150,000. The incorporators are C. H. Waggener, John G. Pritchard, Carl Riggs, and W. S. Black, all of Fairmont, W. Va.

Huntington, W. Va.—The Litz-Smith Coal Co. has been organized with a capital of $40,000 to mine coal. The incorporators are A. L. Litz, of Tazewell, Va., R. I. Smith, of Huntington, W. Va., J. B. Agee, J. G. McGuire, and W. D Spicer, of Logan, W. Va.

Accoville, W. Va.—The H. B. Summers Coal Co. has been organized with a capital stock of $20,000, all of which has been paid in. The incorporators are M. A. Summers, Helen and May Summers, and Harry J. Summers, of Bridgeport, Ohio, and H. B. Summers, of Accoville.

Charleston, W. Va.—The Warrior Coal Co. has been incorporated with an authorized capital of $100,000. The incorporators are planning an early development of 400 to 500 acres of coal in McDowell County adjoining the operations of the Berwind-White Co., with a tipple at War, W. Va.

Piedmont, W. Va.—The Cheat River Coal Co. has been incorporated with a capital of $500,000. The officers are A. R. Balcom, pres., J. C. Mackley, secy. and A. R. Balcom, mgr. and constructing engineer. This firm will mine coal and manufacture coke. It will invest about $70,000 for machinery and plant, and expects to award the contracts for the above between Apr. 1 and May 30.

Duquoin, Ill.—Incorporation papers for a new railroad in Williamson County have been filed with the circuit clerk. The new road will extend from Fredonia, on the Paducah branch of the Illinois Central R.R., to Reeves, on the Johnston City branch of the same road, and will be known as the Fredonia and Reeves Ry. The incorporators are officials of the Illinois Central R.R., who expect to use the road almost exclusively for coal traffic.

INDUSTRIAL NEWS

Winchester, Ky.—Capt. J. G. Jones is negotiating with Eastern interests for the lease of about 1000 acres of coal land which he owns on the Big Sandy River.

Connellsville, Penn.—The Duquesne Coal & Coke Co. has purchased 250 acres of coal at Independence, in Washington County, at a price in excess of $100 an acre.

Stone, Ky.—The Alburn Coal Co. is opening two new mines and will make a large increase in its output beginning Apr. 15. It will put 100 extra men to work. Fifty additional miners' houses will also be built.

Winchester, Ky.—Green A. Combs, of Montgomery Creek, in Perry County, has sold a tract of about 1100 acres of coal land in Clay County to Henry Martin, of Winchester, for $22,000. The tract is located near Manchester, Ky.

Hellier, Ky.—The Henry Clay Coal Co., has increased its coal output from 75 to 100 cars per day and proposes other increases from time to time. It will start another operation in close proximity to the present one the coming summer.

Bristol, Tenn.—The Clinchfield Coal Corporation has contracted with the Seaboard Air Line Ry. Co. to deliver to that firm from the mines in Russell County, Va., 900,000 tons of steam coal. This fuel is to be delivered as it is needed.

Wolf Creek, Ky.—The Wolf Creek Coal Co. which recently started a coal operation here will begin the shipping of coal soon and follow it by increases until a big output is reached. Over 200 miners' houses have been completed, most of which are now occupied.

Herrin, Ill.—Another mining school has been opened by the Miners' and Mechanics' Institute of this state at Herrin, under the direction of E. C. Lee, a well known mining engineer, formerly of Kingston, Penn. The work of the Institute has been made possible recently by act of the Legislature providing ways and means for establishing local schools of this character throughout the state.

Peoria, Ill.—At a meeting of the Executive Board of the Illinois Mining Institute, held at Peoria, Apr. 1, it was arranged that the May meeting of the Institute would be held in Peoria, May 14, 15 and 16. The program will be announced later. Information in connection with the work of the Illinois Mining Institute can be had by writing to Martin Bolt, secretary and treasurer, 1526 South College St., Springfield, Ill.

Waynesburg, Penn.—A deed has been filed in the Greene County Court whereby J. V. Thompson, of Uniontown transfers 8000 acres of coal land in Perry Township to the St. Paul Coal Co., of Pittsburgh. This is the largest single transfer ever placed on record in Greene County. The property is that which was reported as being sold by Mr. Thompson to H. C. Frick. The consideration is given as $1.

Chicago, Ill.—The Link-Belt Co., manufacturers of the Link-Belt silent chain drive for the transmission of power, elevating and conveying machinery, locomotive cranes, power house conveyors for coal, ashes, etc., announces the opening of an office in Detroit, Michigan, in Room 911, Dime Bank Building. L. W. Longman, formerly connected with the Chicago and Indianapolis works of the Link-Belt Co., has been placed in charge.

Washington, D. C.—The U. S. Civil Service Commission announces an open competitive examination to and including May 11, 1914, for the following positions, open to men only: Mining Engineer at a salary of $2400 to $4000 per year; Mine Statistician at a salary ranging from $1800 to $2400 per year; and an Assistant Engineer of Mine Tests, at a salary of $1800 to $2400 per year. Parties interested in any or all of these positions should write the U. S. Civil Service Commission, Washington, D. C., for Circulars Nos. 367, 369 and 368, respectively.

Coal Trade Reviews

General Review

Customary spring activity in anthracite. Bituminous at a standstill, consumers showing no disposition to enter the market. Indications point to a declining market unless there is a rigid curtailment.

The anthracite trade is moving along briskly under the stimulus of abundant orders for April delivery. Tidewater businтss is particularly active, large quantities of coal going into the New England market, with indications that this will continue for two or three months at least. An increase of 25c. per ton in the April retail circular on the prepared grades at New York, as compared with last year's schedule, has created some hesitancy in the local situation there, but the opening business is about normal.

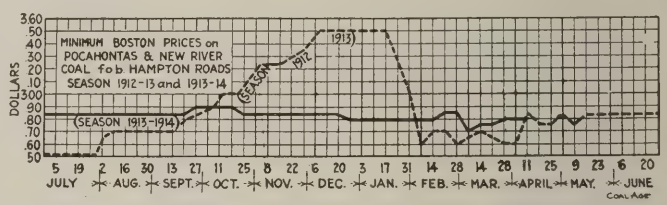
The Eastern bituminous market is at a complete standstill, with no orders, plenty of coal available, and the volume moving under contract away below normal. Concessions are necessary to avoid demurrage, as the market is absorbing coal slowly and buyers are inclined to postpone negotiations. A feeling of hopelessness pervades the trade as competition is close, and it looks like a declining market later.

Production in the Pittsburgh district is at something less than half capacity, there is no recognized circular, and consumers are instructing operators to discontinue shipments until stocks can be reduced; there is no business being done on new contracts, and the new season's schedule has not been announced. The lack of uniformity in operating, pending the fixing of a new wage scale, is aggravating the situation further, and the general outlook is not encouraging.

Although practically all of the Ohio mines are now closed, and neither side making any overtures for a settlement, the market still fails to develop any firmness. The final mine outputs are being delivered, and it is generally thought that most consumers now have a full two-months' supply. The formal opening of lake navigation a week ago Friday has found this business to be equally dull and heavy, because of the excess supply at the head of the lakes and the uncertainty in labor circles. A large number of inquiries are reported at the Hampton Road piers, prices are stationary, and there was a heavy dumping; the curtailment in the union fields, however, has failed to create any unusual activity.

There is a noticeable anxiety over the labor situation in the Middlewestern field, as indications are now pointing to more serious trouble than was anticipated. As yet, however, the market has failed to respond to this condition, even with the added inducement of the customary spring discount. One of the best features of the situation is the large inquiry on contracts, but operators are hesitating to negotiate because of the uncertainty in the labor problem.

EASTERN MARKET



BOSTON

Movement of Pocahontas and New River way below normal and the trade shows rather a pessimistic tone. Unusually large volume of coal at Hampton Roads and market cargoes here are absorbed only with difficulty. Large reserve stocks in New England. Pennsylvania grades dull and heavy receipts of anthracite are expected.

Bituminous—The volume of Hampton Roads coals being applied to contract is way below normal and there is practically no spot demand whatever. At the same time most of the shippers are committed on marine transportation contracts and are therefore obliged to load vessels as they arrive. The market here is absorbing coal very slowly and in order to free cargoes of demurrage the distributors have to make such material concessions that new business and renewals as well are being considerably affected. Buyers are more than ever disposed to postpone and it certainly looks like a declining market later. The threatened Central Pennsylvania strike is regarded here as a flash in the pan affair and practically no interest is shown in it. With 175,000 to 200,000 tons reported standing at the three Hampton Roads ports it is not surprising that the trade here shows a pessimistic undertone.

Large reserve stocks are the rule at practically all the industrial plants, and especially those equipped with auxiliary water power, which is the heaviest in several years and there is no doubt the effect on coal consumption in those sections will be very marked for at least two or three months.

There are no new features in the market for Pennsylvania grades. With practically all the anthracite transportation engaged in moving domestic sizes, Pennsylvania coals are only incidental at tide-water at this time of year. The business is confined to special requisitions and not much is heard in a general way. All-rail there is only a fair movement with a lot of close competition for what new business offers. Prices on the popular grades are being held more or less rigidly and with the level so high and Hampton Roads coals so easy it is only natural many buyers here should turn back this year to the southern coals. It takes a high-grade Pennsylvania coal to withstand some of the low prices that are made to move distress cargoes at the various distributing points.

Anthracite—A heavy amount of April coal is coming forward to dealers all along the New England coast. The ice at the Kennebec and Penobscot rivers is just at the point of going out and soon shipments will be on in earnest. The long-awaited Apr. 1 has arrived and now the sales agents are wondering where business is to come from wren present orders are filled. The outlook is dull for the summer.

Boston prices were reduced 75c. on all sizes except egg on which the reduction is only 50c. This makes egg now the same price as stove. The list is as follows:

Broken	$6.50	Shamokin	7.50
Egg	7.25	Franklin	8.50
Stove	7.25	Bituminous	$4.65@4.90*
Nut	7.50	Screenings	3.00@3.25*
Pea	$5.50		

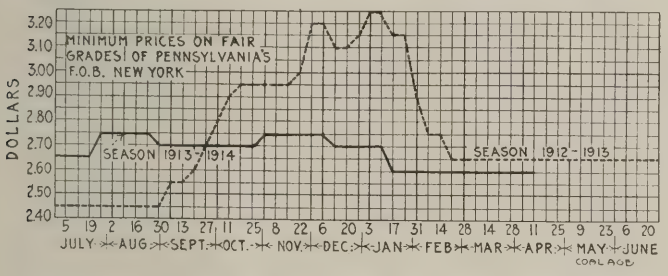
*Higher figure effective after Oct. 1

Bituminous at wholesale is quoted about as followe:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.90	2.92@3.02	
New York*	2.50@3.05	2.80@3.20	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.85
Boston†				3.63@3.73
Providence†				3.60@3.78

*F.o.b. †On cars.

NEW YORK



Interest of the bituminous agencies concentrated on the labor negotiations. Some business in contracts. Note of hesitancy in the anthracite trade due to the change in opening retail circular.

Bituminous—The New York soft-coal market is at a complete standstill. There is no demand, no orders, and plenty of coal on hand at all tide-water points. The entire attention of the trade seems to be concentrated on the labor trouble, and the situation is, of course, hinging to a certain extent upon the outcome of the different conferences now being held. If there is an important suspension in the bituminous regions, there will undoubtedly be a shortage of coal, and on the other hand, if operations are not restricted, the trade is facing a poor summer. In fact, there is a note of hopelessness prevailing in the trade regardless of which way the situation ultimately works out. The operators who will be shut down feel that the others in the nonunion fields will be able to keep the market well supplied and at the same time be the principal beneficiaries.

Some interest is still being shown in contracting. The conservative old-line companies holding out for last year's figures, probably have about half their expiring business renewed, with the balance still hanging fire. Other producers, willing to make concessions no doubt have more than this closed up. The spot market is not quotably changed, and continues the same as for the past several weeks, although

there is probably little or no business being negotiated at these figures: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.70 @2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

Anthracite—The feature of the New York hard-coal market is the new retail price schedule of 25c. per ton on the prepared grades above that for last year. It is stated that 10c. of this increase is made to cover the new Pennsylvania state tax on anthracite, and the balance to provide for increased labor costs, such as the advance granted the boat captains during the winter. A portion of it will also be absorbed by the dealers, as it has been a generally accepted fact for some time that the retail trade has been working on too small a margin of profit. There appears to be some uncertainty as to whether this 25c. increase will be carried through each month and added to the winter circular also; it is reported at some points that the customary 10c. addition will not be made to the April circular on the first of May.

As a result of this increase, there has been some hesitancy on the part of buyers, particularly in New York proper, but as a rule the hard-coal business is about the same as usual during this month. The prepared grades are particularly active all rail, the steam sizes continue short at the upper ports, and rather long at the lower ports. We quote the New York market on the following basis:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$4.60		$4.55	
Egg	4.85	$4.85	4.80	$4.75@4.80
Stove	4.85	4.85	4.80	4.80
Chestnut	5.10	5.10	5.05	5.05
Pea	3.55	3.55	3.50	3.35@3.50
Buckwheat	2.80	2.80@2.90	2.50@2.75	2.35@2.75
Rice	2.30	2.30@2.40	2.00@2.30	1.90@2.30
Barley	1.80	1.80@1.90	1.70	1.45@1.70

PHILADELPHIA

Activity still marks the anthracite trade. Mining in full operation, and all sizes moving off promptly. Bituminous market shows little or no signs of improvement. Little fear of trouble with miners anticipated.

Anthracite—The second week of the spring anthracite business finds the trade moving along under the impetus of abundant orders for all domestic sizes, and a good market for the small or steam sizes but a season of mild weather will find much of this coal going into stock. No. 1 buckwheat seems to be finding the best market, with rice second; pea coal has already felt the effect of milder weather conditions, as evidenced by the fact that the individual operators still find it necessary to concede ten or fifteen cents from the so called circular prices to create a market.

The tidewater business is particularly satisfactory. Large quantities of coal are going to the New England market, and business from this end looks promising for at least two or three months. It is understood that the far Eastern points are rapidly resuming navigation and before the middle of the month, few if any will be inaccessible. The outlook for tidewater trade is bright. Ruling prices are as follows:

	Circular	Individual
Broken	$4.25	$4.35 @ 4.50
Egg	4.50	4.50
Stove	4.50	4.60
Chestnut	4.75	4.75
Pea	3.25	3.10 @ 3.15

Bituminous—While the market as a whole may be characterized as weak, yet there seems to be a tendency toward an improvement. The labor agitation had little effect on the local market, either in the way of added demand, or advanced prices, and what coal has been placed has mostly been on contracts. Prices continue on about a parity with the previous week.

BALTIMORE

Big gain in export coal trade is looked for. Prices firm but market listless. Contracting season draws to close in satisfactory manner.

A considerable improvement is anticipated in the export trade that will somewhat offset the otherwise dull market. Spain, Italy, Mexico, Cuba and South American Atlantic ports are making inquiries of importance. Chartering is such that April will probably see a gain over the same period of last year. March witnessed an increase of nearly 2000 tons.

While the general coal trade is rather lifeless, prices hold quite firmly. West Virginia gas coals vary between 75 and 85c., and steam fuels are selling at the mines at from 95c. to $1. Pennsylvania lower grades readily command $1 to $1.15, and best grades from $1.30 to $1.40. The closing of the contract season finds the majority of April business signed up.

A continuance of cool weather the past week caused some late buying of anthracite by householders with short supplies. The spring business as a rule, however, will be deferred until after the local retail coal exchange sets the new schedule. Considerable interest is felt in the local trade in a city government plan to purchase coal in bulk instead of by department lots. The specifications are rather exacting and a number of coal firms may hesitate to bid as a result.

CENTRAL STATES

PITTSBURGH, PENN.

No market for coal following settlement of wage scale, with some mines entirely closed and others operating part capacity. Many consumers have ordered shipments curtailed or suspended. Prices nominal. Connellsville coke softer, with uncovered consumers buying prompt lots instead of contracting. Production and shipments decreased.

Bituminous—The coal market became flat immediately it became known that there would be no general suspension on account of wage-scale differences. On behalf of the Pittsburgh district it was announced that there would be no suspension, except such closing as was forced by lack of demand. This closing has been rather pronounced. Nearly half the total capacity is temporarily represented in mines closed except for cleaning up work, while mines nominally in operation are running at greatly reduced rates, and shipments from Pittsburgh district mines since Apr. 1 have easily averaged below 50% of capacity.

There is no recognized market price for coal. Prior to Apr. 1 there had been cutting of the regular list to the extent of 10@20c. a ton and such prices could still be found now in all probability if consumers sought them, but instead they have been disposed to instruct operators to discontinue shipments until they can liquidate at least a portion of the stocks they accumulated in expectation of a general suspension. A number of contracts expired Apr. 1 and these must in time be renewed, but at the moment there is no disposition on the part of consumers to negotiate. It is not settled, of course, what prices operators will eventually quote on contracts but their general attitude is that of adhering to the former list, which is now nominally the market, though shaded as to prompt business: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market is quiet and somewhat softer in general tone. Coke operators recognize that iron-market conditions are unfavorable, at least temporarily, and that active furnaces are more likely to blow out than idle furnaces to blow in. The only activity in the past few days has been in prompt lots, which went at $1.95 generally for first-class grade. The purchasers, however, were consumers who had been expected to buy for the month of April as a whole, or even for the second quarter, and the attitude of buyers is that the shorter periods they engage themselves for the better, as they expect to buy at lower figures as time passes. We quote: Prompt furnace, $1.90@2; contract furnace, $2; prompt foundry, $2.40@2.50; contract foundry, $2.40@2.50, per ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Mar. 28 at 360,018 tons, a decrease of 4062 tons, and shipments at 347,490 tons, a decrease of 22,040 tons. Production appears to have exceeded shipments by 12,528 tons.

BUFFALO

Too much bituminous on track, particularly at terminal points. Anthracite about normal. Country delivery hampered by muddy roads. Coke very heavy.

Bituminous—There is practically no regular market to report and will not be any for some time. The output has been cut down materially by suspensions here and there, but

the action is not uniform. Some mines are already starting up, after a short shutdown, and it looks as if others would follow in a short time, as the men are anxious to work and the operators will not curtail production.

This means a market continually overstocked and the consumer making his own prices. For quite a long time there has been little coal shipped, except on contract, that was not urged on the consumer just to get rid of it. As a rule, the consumers are not only much overstocked, but there is a large amount of coal on track, much of it on car service. It would take a month to clean up this surplus and make a firm market possible. At the same time there is demand for slack, though it is not what it was. It is well that it is not selling very brisk, for it is hard to get it while so much mine-run and sizes are awaiting sale. Such a condition pulls the trade to pieces badly, though it makes the Allegheny Valley slack as high in price as Pittsburgh, in spite of the lower freight. The general outlook is not encouraging as a whole.

Quotations remain weak and uncertain on the basis of $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run, and $2.25 for slack, including Allegheny Valley, although other sizes of this coal are about 25c. lower than Pittsburgh.

Coke—As anticipated last week the report of a possible advance in foundry coke has not materialized. The trade is as dull as ever and any increase of output would be disastrous. Consumption is not increasing, and prices continue on the basis of $4.50 for 72-hr. Connellsville foundry.

Anthracite—There is a good April trade in all branches of the business, although country jobbers complain of bad roads that interfere with deliveries. The excess of egg coal continues and it is predicted that some new plan for breaking coal will have to be adopted sooner or later. The loading of anthracite for lake shipment continues slowly, more than 20 cargoes now being afloat. Not much more will be done at present, as there is little demand for it at upper-lake ports and the prospect is for a late opening of the lake trade. Vessels will hold back as long as possible, as there is no iron ore for down shipment yet.

TOLEDO

The trade here is waiting future developments. Price lists are entirely off and everything unusually quiet and dull. Opening of navigation.

There is no perceptible change in Toledo. With a strike on, the conditions here are little different from what they have been for many weeks. Everything is decidedly dull. During the week it has been impossible to move the small quantity of track coal, held in the local yards, even at big concessions. Consumers either stocked sufficient to last during a brief suspension or will depend upon West Virginia coal. It is thought that the majority have enough accumulated stock for at least a month or six weeks. The railroads, have at least a two months supply on hand and one of the largest factories announced that they had enough to last until the end of June.

The demand for domestic, which was the life of the trade during the past six weeks is now entirely dead.

The length of the Ohio strike is the determining factor in local conditions. Most of the operators are of the opinion that it will last for some time.

Navigation was formally opened on Wednesday. Considerable coal has already arrived here for lake shipment. Large tonnages are held for this purpose on the east side awaiting the opening of the Pennsylvania bridge.

Prices are quotable as follows:

	Pocahontas	Kanawha
Domestic lump	$1.60	$1.40
Egg	1.60	1.30
Nut	1.40	1.25
¾ lump	1.25	1.15
Mine-run	1.25	1.10
Slack	....	0.65

No prices on Hocking, Jackson, Pomeroy, Massillon, Pittsburg and Cambridge.

COLUMBUS

Trade at a standstill. Practically no coal produced and the demand weak. No indications for a renewal of the wage agreement have appeared.

As anticipated, practically all of the operators in this state closed their mines Mar. 31 and they will remain closed until a satisfactory wage agreement is signed. As a result after the first two days of the week there was no production of consequence. Both operators and miners have been playing a waiting game and no move has been made toward a renewal of the conferences. Neither side is sure of their ground as the passage of the mine-run law has seriously complicated matters.

While the policy committee of the United Mine Workers of America announced that the miners would be willing to work pending negotiations on the wage agreement, the operators decided to close down their mines. They have not yet taken any action to test the constitutionality of the mine-run law and cannot until after the referendum period is over which is about May 20. In the meantime the attorneys will canvass the situation and outline a plan of action to be followed.

So far no effort has been made toward putting tipples and plants in shape to comply with the new law. This work will require several months and an expenditure of $2,000,000 to $3,000,000. The operators appear to be well organized and are standing solidly against resuming work before a number of disputed points are settled. The market is in such a condition that a suspension of 60 days would not hurt anybody and would result in cleaning up stocks nicely. It is freely predicted that when work is resumed coal will be sold at a higher figure than prevailed since the first of the year. It is believed the cost of production under the new law will be advanced fully 8 to 10c. per ton.

The indications for the lake trade are not very promising. Reports from the Northwest show there is still a considerable tonnage on the docks of the upper lake ports. There will not be much demand for lake tonnage before the middle of the season.

What quotations are being made in the Ohio fields are as follows:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump	$2.07	$2.30@2.40	$2.12	
Steam lump	1.97		1.97	
Egg		2.30@2.40		$3.65
Mine-run	1.87	2.15@2.25	1.87	3.30
Screenings	1.67	1.85@1.95	1.62	

CLEVELAND

Lake coal shipping started last Friday at Huron. The suspension in Ohio failed to bring any appreciable benefit to the market and prices rule on the low level of the last few weeks.

Every commercial mine in Ohio closed down Tuesday night, and most of them will remain closed for some time. Although consumers realized the threatened suspension was not a myth, they did not come into the market with a rush; much stocking has been done in this district and little may be expected in the way of improvement in the near future.

The last coal mined in Ohio under the old contract has reached the markets, but it is not expected it will sell readily. The local trade has been carrying between 500 and 600 cars of coal, which will not be moved in less than two weeks. Prices continue low because operators and jobbers must sell coal to avoid car service.

Anthracite is coming to retail dealers and as many of the retail yards have large stocks of soft coal they are somewhat crowded.

Lake shipping began Friday when a small steamer and barge left Huron with coal for St. Clair River ports. Another steamer and barge cleared Saturday for river points. Coal is arriving for lake shipment in small quantities. The B. & O. is accepting lake coal only when the vessel is waiting at Lorain to load. The B. & O. machines at Lorain went in operation Apr. 10.

Coal shippers are not actively working among vessel owners. The situation at the mines in Ohio and parts of western Pennsylvania is so uncertain they cannot be sure of having coal and there will be no demand from the upper lake ports for at least sixty days. It is said among shippers that additional chartering of vessel capacity will not be done for another three or four weeks.

The spot market is quotable as follows:

	Pocahontas	No. 8	Middle District	Fairmount	Youghiogheny
Lump, 1¼ in.	$2.75@2.90*	$1.90@1.95	$1.80@1.85	$1.90	$2.25
Egg	2.75@2.90*				
Mine-run	2.55@2.60*	1.85	1.80@1.85		2.15
Nut		1.90	1.80		2.00@2.05*
Slack	1.25*	1.75	1.70		1.90

*For coal shipped or en route.

CINCINNATI

Closing down of Ohio mines stirs local demand. Trade looks to West Virginia and Kentucky for tonnage. River movement steady with all harbors, down to New Orleans, well supplied.

The trade here is now passing through a transitional period and the market is rather quiet. The demand for shipments from Kentucky and West Virginia has been greatly emphasized since the closing of the Ohio mines last week. Operators in the Southern districts are watching with the

keenest interest the events now taking place north of the river, and while the majority of the dealers here believe that the situation will be relieved in the near future, Southern producers are making every effort to increase their production.

The rail movement through here is about as heavy as the lines North can take care of. This will be greatly relieved, however, by the diversion of C. & O. coal to the Hocking Valley for distribution in the central and northern parts of the state. Every harbor from Cincinnati to New Orleans is well supplied, the river movement having been steady.

In some quarters it is said that the domestic trade is at a complete standstill, which condition will likely continue for some time, as retail dealers show little disposition to put in stock for next winter. Producers are sanguine that dealers will begin calling for shipments within the next few weeks which will have a tendency to relieve the market.

DETROIT

Improved demand and outlook is brighter. Activity on contracts for the new year.

Bituminous—The local situation has cleared up somewhat, and the indications are brighter for a good healthy business the coming season. The demand has quickened and a more optimistic feeling prevails. There has been a great deal of activity in contracting particularly, and considerable business is said to have been closed at profitable figures. Operators are showing no particular anxiety to close contracts, and are exercising some care in taking only what business they want. Some small premiums have been offered for light consignments of track coal, but this is rather the exception than the rule.

Coke—The situation is practically unchanged with the demand only fair for this time of the year. Indications point to increased business shortly. Connellsville is quoted at $3 with Sement Solvay at $3.25, and gas house at $2.90, all f.o.b. ovens.

HAMPTON ROADS

Week's shipments heavy. Dumpings for month of March more than one million tons. Prospects for heavy movement during April.

The dumpings over all piers at Hampton Roads have been good and the demand for coal is much better than it has been for some time.

Prices remain stationary. From the number of inquiries in the market for coal for prompt movement indications are that shipments will be heavy during the current month.

Foreign shipments for the week have been to Naples, St. Lucia, Cuba, Montevideo, Canal Zone, Georgetown, Coronel, Port Morant, Ceara and Manoz. In addition to the foreign movement the coastwise shipments have been heavy.

The Norfolk & Western Ry. at Lamberts Point made a new record for fast loading on Mar. 28 when they dumped 7751 tons of cargo and bunkers into the S.S. "Middlesex," this coal being put aboard in the short space of 4 hr. and 10 min. The best previous record out of this port being 4 hr. and 50 min. for a like quantity of tonnage.

Shipments of coal out of Hampton Roads for the month of March amounted to over one million tons of which quantity the Norfolk & Western Ry. at Lamberts Point dumped 532,525 tons, the Chesapeake & Ohio Ry. at Newport News 331,633 tons and the Virginian Ry. from Sewalls Point 222,803 tons.

LOUISVILLE

Continued mild weather stops the domestic movement and business is at a low ebb. The steam market is equally weak. Suspensions in other districts have had no effect as yet.

In spite of the stiffening which should normally follow a suspension of operations in other fields, the market in this territory is extremely weak, owing largely to the practical cessation of the movement of the prepared grades. Retailers report that there is no demand whatever, and as yet they have shown no inclination to begin stocking in anticipation of the summer business. The expected suspension in western Kentucky will not improve things appreciably, as there is simply no market for coal at this time.

The steam market is also slow, despite the scarcity of screenings which might be expected to follow a weakness in the domestic market. This is due to the inactivity in many industries, resulting in a lessened need for fuel and low prices, ranging from the rock-bottom figure of 35c. for western Kentucky nut and slack to 75c. or thereabouts for the better grades of eastern Kentucky, with few sales. It is reported that 6-in. block has been offered as low as 85c., indicating a market so quiet that it might be called quite dead.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM

Lump coal and steam coal very quiet. Furnace and foundry coke show little change and blacksmith coal is normal. Car supply satisfactory. Spring prices on Cahaba coal.

With the coming of summer weather, all spot business on lump coal has vanished, and while spring prices are now prevailing, business, so far, has been short of expectations. However, the next thirty days will show heavy bookings of lump coal for summer and fall shipment. Following are prices on standard Cahaba nut, No. 2 lump and fancy lump.

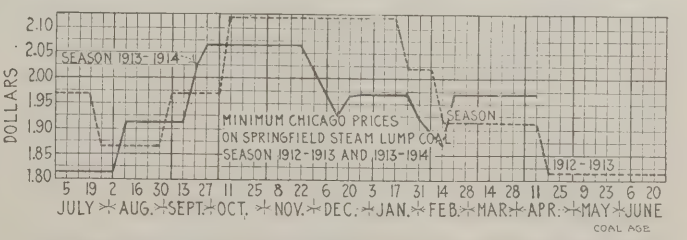
	2x5 Nut	No. 2 Lump	Fancy Lump
April	2.00	2.25	2.50
May	2.10	2.35	2.60
June	2.20	2.45	2.70
July	2.30	2.55	2.80
August	2.40	2.65	2.90
September	2.50	2.75	3.00
October	2.50	2.75	3.00
November to March	2.75	3.00	3.25

These prices are based on business being normal. Should the winter be cold they will advance, but if mild they would drop.

The steam coal business is far from being satisfactory, but the operators are expecting an improvement within the next ten days or two weeks. There is little or no change in the furnace or foundry coke market, it still being very quiet. Blacksmith coal is about normal. Furnaces report only small sales of pig iron for last week, with prices around the $11 mark for 2 Foundry f.o.b. Birmingham. The car supply is satisfactory.

INDIANAPOLIS

Fair domestic trade due to cool weather requiring continuance of furnace fires. Steam grades moving about the same. Industrial demand improving and some storing still being done. Prices hold steady.



The weather continues cool and there is still a fair trade in domestic coals in Indiana. The demand for steam grades continues about the same; an improvement was expected but the industrial situation has not picked up. However, building operations have a start now and this will mean more activity generally. It is also the time of year when the automobile factories make a good showing. While these are far from being at full capacity, yet, they show considerable improvement over their winter schedule. Some other lines are also more active.

All this, added to the storing of coal by the larger buyers, because the new wage agreement is not yet signed, gives Indiana mines fairly active going. It is noted in this city that some consumers of domestic grades are laying in stocks of coal while they are sure they can get it. There is considerable inquiry concerning contracts for next year, but some hesitancy on the part of operators in quoting old prices during the pending uncertainties. Some of the mines have closed for repairs and a few hundred miners have taken advantage of this and of the delay in reaching a wage agreement and have left for Europe for a few weeks' vacation. Some mines were closed Apr. 1 that the miners might celebrate the aniversary of the eight-hour-day law. Prices continue generally unchanged.

CHICAGO

Summer discounts and labor troubles fail to stimulate business. Considerable activity in contracting with new business at last year's figures.

The expected movement toward a large storage of coal in preparation for a mine suspension did not materialize and a flat and dull market is the result. The general reduction in prices for the summer did not seem to aid the situation to any appreciable extent.

Contracting continues to feature the smokeless coal market, with the larger portion of the Chicago business all

closed although there is still some which is not as expeditious as was expected. Satisfactory conditions prevail in spot business with a number of concerns entirely sold up for delivery of prepared coal in April and May and more than half sold up on June and July delivery. Prices are steady at $1.25 for mine-run up to Aug. 1 and $1.40 after that date. For lump and egg the price is $1.60 for April, $1.70 for May, $1.90 for June, $2 for July and $2.25 for August and probably the balance of the year.

Conditions have been unusually dull with regard to the Hocking situation as a result of the energy of dealers who aided their customers in filling up before the mine suspension. Franklin County, Carterville and Harrisburg mines are awaiting the outcome of the labor situation, and they have provided their contract customers with as much coal as they could be induced to take. The belief is that there will be no serious interruption to mining. Similar conditions prevail in Indiana with an expected shut down of from two to three weeks; it is understood that the market is well enough stocked to withstand this.

Prevailing prices in Chicago are:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.45 @ 1.35	.....	$1.50 @ 1.40	$1 40 @ 1.35
¾ inch	1.30 @ 1.25	$1.20 @ 1 15	1.35 @ 1.30	1.30 @ 1.25
Nut	1.25 @ 1.20	.....	1 30 @ 1.25	1.25 @ 1.20
Mine-run	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack	0.85 @ 0 80	.....	0.90 @ 0.85	0.75 @ 0.70
Coarse slack	0.75 @ 0.70	1 00 @ 0.95	0.80 @ 0.75	0.65 @ 0.60

Coke—Connellsville and Wise County, $5@5.25; byproduct egg, stove and nut, $4.45; gas house, $4.25.

ST. LOUIS

Labor situation takes an unexpected turn for the worse and some anxiety now evident. Nearly all mines shut down. Prices unchanged but tending to advance.

There is a feeling of anxiety in the local coal trade circles as to the future developments in the labor situation in the Illinois field. In only a few instances has there been much storage coal bought by the steam plants here but the developments of the past few days have caused a great deal of anxiety as indications are that things will not be as smooth as was anticipated by the railroad interests. These latter were advising the public all the time that there would be no strike, but in the meantime they were shipping all the coal they could get for railroad storage purposes, taking advantage of the cheap prices that prevailed on account of the rumor that there would be no protracted shut down.

Some of the mines in the Standard district are working but only a few. There are no mines being operated in the outer districts, as far as can be learned. The circular prices as quoted in the last issue are practically the same, with the exception of screenings. The market at the close of last week on Carterville screenings was 90 to 95c., with a tendency to bring $1 and only a little offered. The Standard market was about 65 to 70c., with a tendency to go to 75 and 80 cents.

There is no washed coal on the market, and nut coal is somewhat scarce from all fields. Egg has moved more freely than lump, so that such mines as have coal on track have nothing but lump.

KANSAS CITY

Market generally steady. Increased production of cheap steam-shovel coal causing a readjustment of trade conditions.

Demand for lump is at a standstill, while steam coal is showing improvement. The market is generally steady, though Cherokee lump is badly off because of competition with the steam-shovel operations in the Pittsburg and other fields. With the arrival of good weather, the steam-shovel mining is progressing at an increased rate, with the result that shaft operators are finding themselves at a marked disadvantage. The cost of shovel mining is much less than by shaft, though that method does not allow as large an output as the latter. Operators mining Cherokee lump are finding it impossible to compete with the steam shovels and the situation is causing a good deal of uncertainty. It appears as if the shaft operators will be able to sell only surplus demand which cannot be cared for by the shovel mines.

FOREIGN MARKETS

GREAT BRITAIN

Mar. 27—With the approaching of the Easter holidays and heavier chartering of late, the outlook is more promising. Prices are approximately as follows:

Best Welsh steam	$4.35	Best Monmouthshires	$4.09
Best seconds	4.20	Seconds	3.90
Seconds	4.08	Best Cardiff smalls	2 60
Best dry coals	4.14	Seconds	2.52

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are net f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days.

FOREIGN TRADE OPPORTUNITIES

The United States Consular Service reports opportunities in foreign coal markets as follow: complete details regarding different items can be obtained on application to the Bureau of Foreign and Domestic Commerce, Washington, D. C., by giving numbers:

A foreign business man informs an American consular officer that he is anxious to introduce American coal into the country in which he is located, and has just entered into negotiations with a Government official in reference to supplies of American coal. There is a disposition to buy such product provided the quality compares favorably with that of Cardiff coals. If American firms can compete it is believed that 200,000 tons of coal can be disposed of. Translation of the specifications which cover the purchase of Government supplies accompanied the report, and can be obtained by interested firms from the Bureau of Foreign and Domestic Commerce. —**No. 12,790.**

The Bureau of Foreign and Domestic Commerce is in receipt of a communication from a trade organization in the United States stating that one of its officials will make a trip to a European country in several months for business purposes. He desires to take advantage of this opportunity to introduce American coal into the country in question. He states that he has good connections in the market and believes that the time is opportune for establishing a permanent trade in this article.—**No. 12,777.**

PRODUCTION AND TRANSPORTATION STATISTICS

ANTHRACITE SHIPMENTS

Anthracite shipments for March and the first three months of the current year as compared with last year were as follows:

	March		3 Months	
	1914	1913	1914	1913
Phila. & Reading	936,304	976,712	2,698,223	3,399,293

Cut out the branch trolley lines in your mine when they are not in use with

Westinghouse

Automatic Section Insulators

Westinghouse Automatic Section Insulator

Top View of Westinghouse Automatic Section Insulator

BRANCH trolley lines protected by these insulators are only energized by the locomotive throwing the insulator switch when entering the branch.

The circuit is opened and closed by a switch blade mounted on a rocker which the trolley operates. In one position the blade connects with copper contacts, in the other there is no connection. A spring prevents the rocker from remaining in an intermediate position.

There is no arcing at the switch contact, because the rocker is always energized, and the switch connection is always closed while the trolley wheel is on the rocker.

This device complies with the Pennsylvania Bituminous Mine Law of 1911, Section 41, Page 67, which requires that branch trolley lines be fitted with automatic trolley switch, etc.

It's Up To You!

The Weekly Ad-Talk Page

Advertising has done great things for you, reader.

It has cheapened the cost of goods by making the marketing easier and less expensive.

It has forced the manufacturer to keep his eyes and ears open for suggestions and recent inventions.

It has forced the retailer to have a cleaner store; a larger force of trained clerks; a better system to take care of your wants.

Advertising has broadened competition. It has made progress vital. It has opened the markets of the world.

The opened market has forced the advertiser to keep ahead of his competitor.

For this reason one big concern pays a man a fabulous salary to study and improve the devices it manufactures.

Every onward, upward step in the technical world is reflected in the selling section of this paper.

It is an index of technical progress.

Are you measuring your steps by it?

When you keep step with the development of your field, your efficiency keeps a jump ahead of the man who is content to putter along with yesterday's success.

In this issue you will find some new device, some labor or time saver that marks another onward step.

Advertising has done great things for you, reader. Have you benefited?

COAL AGE

Vol. 5 NEW YORK, APRIL 18, 1914 No. 16

Mr. Mine Manager, what do you know about mine rolling stock?

When you purchase mine car wheels, these days, you are not limited to one type of wheel, as you were some half dozen years ago; you may make your choice, for instance, from at least a dozen different designs of self-oiling wheels; probably an equal number of roller-bearing patterns, to say nothing of ball bearings and others.

Have you, at your finger ends, any positive information that would justify you in eliminating some of these types from consideration and allow you to choose intelligently from the balance?

To be more specific; let's assume that in one of your mines you have a long motor haul where you are now pulling your cars at the rate of about five miles per hour. It appears that because of the rapidity with which you are driving the narrow work, that it will soon be necessary to increase your haulage speed to eight miles per hour, and, eventually, to twelve miles per hour. Do you know whether the wheels you now have in service on your mine cars, will stand up under such speeds; and, if not, do you know of any type of wheel that will?

Let's go a little farther. Do you know whether it costs more to lubricate the self-oiling wheels, using black oil than the roller-bearing and ball-bearing wheels that require an entirely different kind of lubricant?

Do you know the difference in drawbar pull between cars equipped with any one of the types of wheels mentioned, in contrast to any other one type.

Have you any figures showing the comparative life of any two of the types of wheels mentioned? Do you know whether some of these types are especially adapted to slope hauls, while others are peculiarly adapted to practically level hauls?

Come now—fess up; you need not be ashamed of your ignorance! Listen to this:

So far as we are aware, not a single mining corporation has covered such an investigation, intelligently and fully —or at least, if they have, they have not seen fit to take the mining fraternity into their confidence.

Surely the inventors of these different types of wheels are deserving of some kind of a hearing; and as for the owners of our mining property, you know they need all the dollars that can be wrested from present cost sheets.

Get busy: If we have misstated your experience, tell us so emphatically; we won't take offense.

Ideas and Suggestions

Getting Results

By William H. Schaeffer*

An intelligent imitator always gets *some* results. He is up and doing while the other fellow, hoping to find a file of Original Ideas dropped upon his desk, finds himself shriveling up in the Chair of Opportunity.

Action generates originality, and it takes originality to imitate, paradoxical as that may seem. The original man takes an original way to better results. The old way was to survey the road yourself and erect from personal experience the necessary guide posts. The new way, the original way, is to study first the accounts of the journeys that other men have made over the same ground, marking down in your mind the pitfalls, the soft spots, and the treacherous places that they have encountered, and then going ahead and side-stepping all of these known difficulties. Then when the unexpected difficulty comes, you can meet it more easily because it was the *only* obstacle you didn't know about and you have conserved your full strength to concentrate upon it.

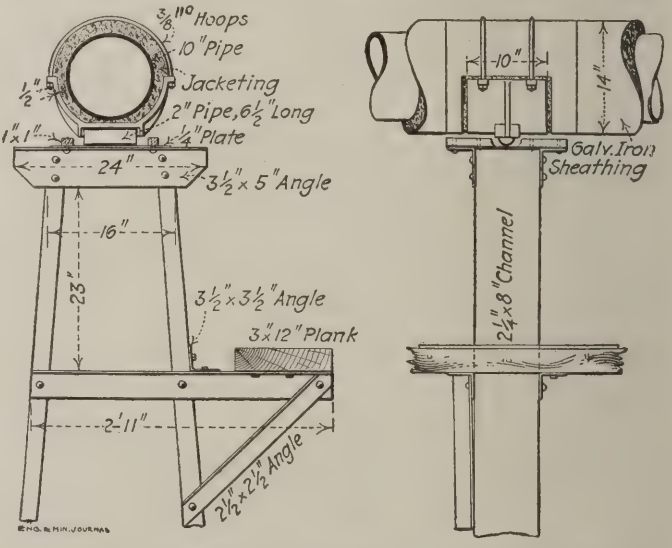
You never will find two problems in real life identical. The art of adapting to one business the principles developed in another seems to be the fountain of efficiency, and is actually as simple as A. B. C. On that idea alone, efficiency engineers have enabled themselves to really earn big remunerations from shrewd business men, who failed to grasp the simple idea involved.

Individual experiences are but illustrations of the application of the principle they strive to carry home. Don't hitch the cart before the horse and regard the principle as the example and the experience as the fundamental truth involved. That's what the fellow is doing who is up against the problem that is *"so* different."

The same principle is now being adapted to coal mining and if by a study of technical literature, you dig for ideas as conscientiously as you dig for coal, you won't be covering the road of Progress between Here and Best Results without knowing before you start the maps that others have laid out in the territory affected.

Surface Steam-Line Supports

The accompanying illustrations show the method adopted in the Norrie group of mines at Ironwood for supporting an outdoor steam pipe. The steam is conveyed some distance from the boiler house to the hoist at one of the shafts. The pipe is carried on the structural-steel bents shown in order to maintain the desired grade over the variable ground.



The bents are spaced about 15 ft.; every 200-ft. approximately a slip joint is inserted to take care of expansion. This is carried on the structure shown near the center of the photograph. The bents are set on concrete foundations to which they are held by plates bent at an angle, riveted to the legs and bolted to the concrete. The 3x12-in. plank supported on angles along one side, serves as a walk when it is necessary to inspect the pipe or pack the slip joints. The cross-braces are spaced 3½ ft. center to center and as many are used as the height of the bent requires.

*Akron, Ohio.

Pipe Line from the Boiler House

The manner of holding the pipe on the top of the bent so as to permit longitudinal motion, is of interest. The pipe is jacketed with insulating material and sheathed in galvanized iron wired on. A cast saddle at each bent is

Top of a Bent, Showing Saddle and Roller

bolted to the bottom of the pipe with two ⅜-in. bolts, over the top. The bottom of this casting is a socket which fits over a short section of 2-in. pipe. This pipe acts as a roller; it is free to roll longitudinally on a plate which forms the top of the bent, but is held against lateral motion by 1x1-in. pieces riveted to the plate. The details of construction of the top of the bent are evident from the drawing.—*The Engineering and Mining Journal.*

Cost Sheets--Their Uses and Their Limitations

By J. B. de Hart*

SYNOPSIS—The daily cost sheet, while indispensable to the mine foreman as a record of the daily expenditures of the company, is, necessarily, an imperfect record of the production cost and should, therefore, be supplemented by a weekly or fortnightly cost sheet.

The output of most coal mines includes a daily cost sheet. Let us consider for a few moments what this record shows, and of what use it is. In the first place, the term "cost sheet" is liable to be misleading. A daily cost sheet does not, and never can, show the actual cost per ton of coal mined. What it does show is the daily expenditure of the company and the way in which this money has been spent. A glance at the figures at the end of a cost sheet, "total cost $x. per ton," shows us simply nothing. In order to be in a position to use the cost sheet to the best advantage we must first come to a realization of this fact, and we must also learn whence the inaccuracies arise.

Let us first consider the item "Mining Materials," which includes timber, rails, pipes, planks, sheet iron, and so forth. The supply of timber which is sent down a mine each day does not vary to any large extent, except as the mineral output varies. At most mines, however, rails are sent down not every day, but once in about every three days. The usual method of procedure is for the foreman to write an order on the warehouse for the rails, and the cost of these is charged against the output of the mine on the day when the order was written, shown by the date on the order.

Clearly these rails should have been charged against the total output for the three days, and not against the production of any single day. If they are room rails, or rails not used in a main entry, they will be taken up and used over and over again, and so will help to produce a large amount of coal. Yet, on the cost sheet, they are charged against the output of a single day.

Overcoming the Difficulty

The question naturally arises, "How can we overcome this difficulty?" Clearly, it is impossible to postpone the making up of the cost sheet until the rails are worn out, or buried beyond hope of recovery. The best we can do is to get out a cost sheet covering all three days, and such a plan will eliminate the greater part of the error. This is a simple matter, and hence we find at most mines, not only daily, but also weekly or fortnightly cost sheets. Such cost sheets show a much nearer approximation to the cost per ton for a given period, although they are not absolutely accurate.

Let us suppose that there is a cave on one of the main roads, and that it takes a week to have it repaired. This work is usually charged to the output for that week, and, other things being equal, we get a too high cost per ton for that week. To be accurate we should spread the cost for this work over the whole output for a period equal to the average time which elapses between the days when we spend a week repairing caves. For example, if we, at the end of a year, have spent one week only repairing such caves, then the cost should have been borne by the whole year's output; if we have spent four weeks at such work, then the cost of the one week should have been borne by the output for three months. It is as well to realize this fact; that even a fortnightly cost sheet does not show an absolutely accurate cost per ton. Nevertheless, a fortnightly cost sheet does under ordinary circumstances show a cost per ton which is accurate enough for all practical purposes.

In spite of its defects, a daily cost sheet is indispensable to the mine manager. It must be looked upon, however, as showing the distribution of labor cost, and not the true cost per ton, or the cost per ton of material. It shows us the disposition of the forces; it shows the proportion of shiftmen to miners, of undercutters to miners, and the output per miner and per man. With all of these facts the mine manager must be familiar in order to cut down expenses to a minimum. On the other hand, we must always bear in mind that it is necessary to look further into the matter than the figures shown by the daily cost sheet, before we can confidently go to the mine and say to the foreman, "Your cost for material is going up."

*Coleman, Alta, Canada.

Dewatering Coal after Washing

One of the most difficult problems in connection with coal washing, in the past, has been the dewatering of the coal, after finishing its treatment in the washer. This difficulty seems now to have been successfully overcome by two companies; namely, the American Concentrator Co., of Joplin, Mo., and Springfield, Ohio, and the Link Belt Co., of Chicago, Ill.

Each of these companies has been experimenting with machines, during the past year, and they have now reached a point in their investigations where they are accepting orders.

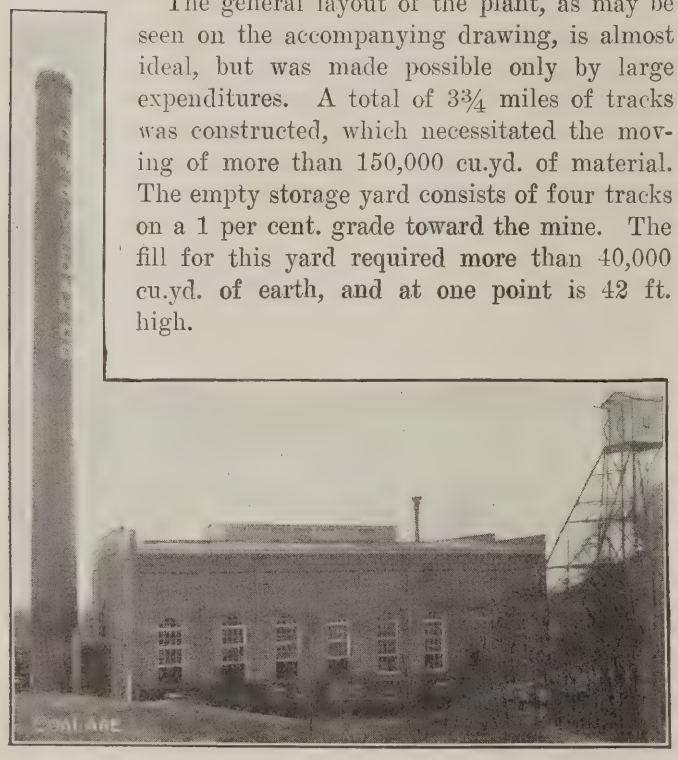
The American Concentrator Co. installed their experimental dryer at the plant of the Pennsylvania Steel Co., at Steelton, Penn., last summer, and now, within a month, will have two large washer installations in operation using their machines; one in Alabama and one in Pennsylvania.

The Link-Belt experiments were carried on at the plant of the Illinois Steel Co. and they have recently closed a contract for a plant in Alabama, which calls for the installation of their dryers.

Both machines are centrifugal in action, and, their makers claim, will deliver coal after treatment with a uniform moisture content not to exceed 6 per cent. Heretofore, the owner of a washery had his choice of storing his washed coal in bins, for several days, and then elevating it with cranes and grab buckets, or else taking it directly from the so called dewatering elevators, with its moisture content varying anywhere from 7 to 20 per cent.

Another advantage which will, no doubt, accrue from the use of these dryers, will be the entire recovery of the very fine coal that ordinarily floats off with the waste water.

Development along this line will be followed with a great deal of interest by all who are interested in coal washeries.



A Modern Illinois Coal-Mining Plant

By R. G. Read*

SYNOPSIS—A Southern Illinois coal-mining plant where the machinery and equipment are thoroughly up-to-date.

The new plant of the Chicago, Wilmington & Vermillion Coal Co., located at Orient, on a spur connecting with the Chicago, Burlington & Quincy, and the Chicago & Eastern Illinois Rys., is the first of a series of plants to be constructed for the development of a tract of 7000 acres of coal owned by this company in Denning Township, Franklin County, Ill.

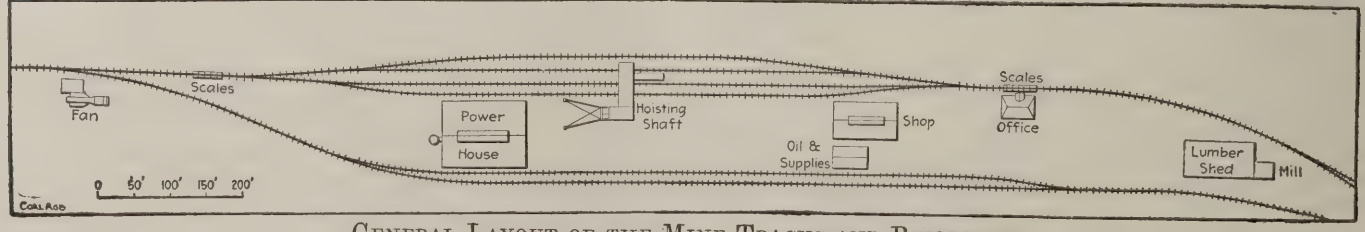
The general layout of the plant, as may be seen on the accompanying drawing, is almost ideal, but was made possible only by large expenditures. A total of 3¾ miles of tracks was constructed, which necessitated the moving of more than 150,000 cu.yd. of material. The empty storage yard consists of four tracks on a 1 per cent. grade toward the mine. The fill for this yard required more than 40,000 cu.yd. of earth, and at one point is 42 ft. high.

General View of the Power Plant

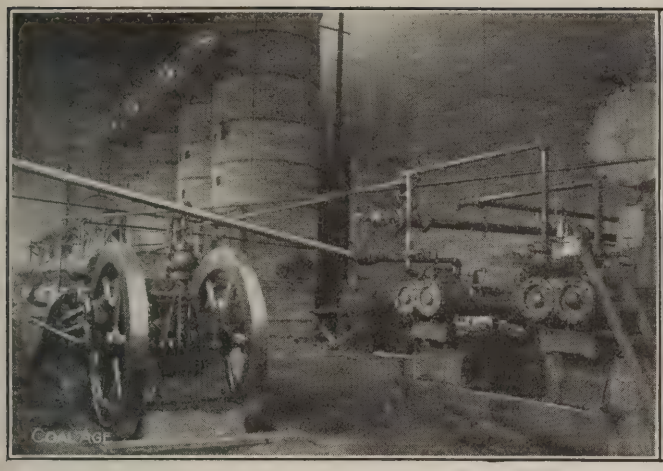
The shaft is 520 ft. deep, and the point of dumping in the tipple is 70 ft. above the ground surface, making a total lift of 590 ft. Separate hoisting and air shafts have been constructed, each being 11 ft. 6 in. by 18 ft. in the clear and lined with 10-in. reinforced concrete extending from the surface to the bottom of the shaft. The air shaft, furthermore, has a reinforced-concrete partition separating the airway from the stairway compartment. An auxiliary hoist for men and material will be here installed.

The town site is located on rolling ground, and is provided with modern conveniences, including electric light and running water in each house. A hotel and 75 dwellings have already been completed.

The mechanical equipment was designed for a working capacity of 4500 tons per day of eight hours. In order to handle this output it was realized that a maximum hourly capacity of 1000 tons would have to be attained. The hoisting and screening equipments were, therefore, designed with this end in view. Special attention was given to simplicity and strength of the various machines, so that the risk from delays due to breakdowns would be reduced as far as possible. The question of economy in power consumption was also given careful



View of the Shaking Screens



consideration, with the result that the steam consumption per ton of coal produced is small.

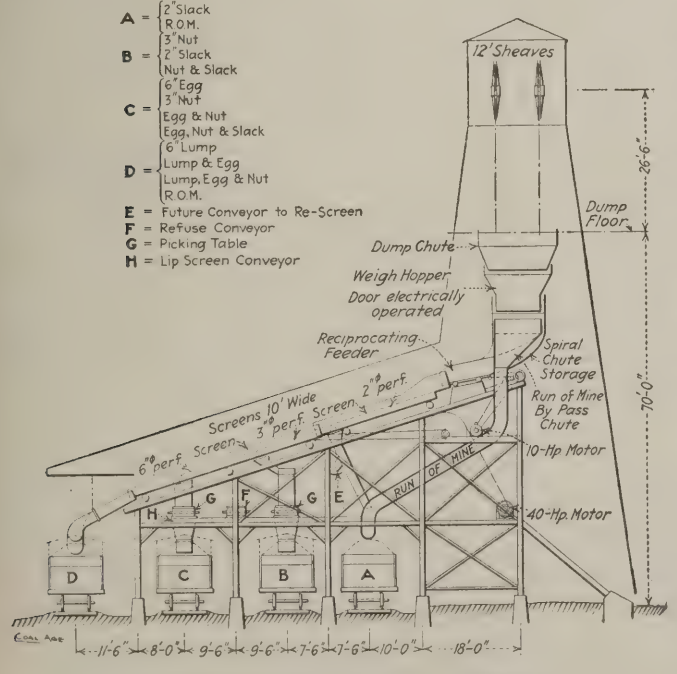
The tipple and screening equipment was given much thought with a view to thorough preparation of the coal. A side elevation of the tipple is shown in the accompanying drawing. The plan adopted for the mine rendered it desirable to place the hoist at right angles to the screen. The coal is dumped by means of self-discharging cages into a chute from which it flows by gravity into a weigh-hopper, provided with automatic recording scales and an electrically operated gate through which it is discharged into a "spiral" chute 10 ft. wide. This provides both a means of bringing the coal to the center line of the

*Webster Bldg., Chicago, Ill.

General Layout of the Mine Tracks and Buildings

A View in the Boiler Room

The Hoist and Generator Room



screen and a considerable amount of storage with a minimum of breakage.

This storage (about 20 tons) enables the dumping to proceed when the screens are for any reason momentarily stopped. A reciprocating motor-driven feeder which may be stopped or started at will delivers the coal to the screen.

The screens themselves which are perhaps the largest ever constructed are 10 ft. wide, each, with one perforated and one blank deck. No veil plates have yet been used for making the several mixtures indicated on the drawing. A separate steel structure supports the oscillating parts so that vibration is not transmitted to the hoisting tower or tipple building. A run-of-mine bypass chute independent of all machinery is provided for use in case of emergency.

The picking equipment consists of two 4-ft. tables of the apron type for the egg and nut sizes. Each table is about 25 ft. long and is carried by an independent steel frame. These tables are pivoted and provided with a hoisting mechanism so that they can be raised to discharge into chutes leading to box-cars when desired.

The refuse removed from the coal in the picking operation is thrown upon an apron conveyor and discharged into a 50-ton bin over the egg track. For all of these conveyors separate motor drives are provided. A combined picking table and loading boom for the lump coal will be installed in the future as well as a rescreening plant for separating the small sizes. The high class of construction of this machinery may be judged from the accompanying photographs.

Cross-Section through Tipple

The power house is a brick building, 90x114 ft., with steel roof and concrete floors. The boiler plant proper at present consists of four 400-hp. Wickes vertical water-tube boilers fired by Green chain-grate stokers. Provision is also made for adding two more future boilers which will bring the total capacity up to 2400 hp. Brick flues or smoke ducts connect the boilers to an 8x175-ft. Weiderholt reinforced-concrete stack. A tunnel has been built for the handling of ashes, and a coal-handling equipment with a bunker is to be installed in the future.

The hoisting engine, which is located in the power plant proper, is a duplex Nordberg Corliss 28x48 in., driving a 10-ft. drum. This is believed to be the first engine of this type to be installed in this field. The electric energy is furnished to the mine by a 300-kw. Crocker-Wheeler generator direct connected to 22x30-in. Nordberg Corliss engine. Space is provided for two similar additional units. A 35-kw. generator for lighting is also installed so that the large unit is used only during working hours. A small air compressor is also provided for cleaning boilers, riveting, etc.

A Jeffrey 6x16 ft. ventilating van direct connected to a 22x30-in. Nordberg Corliss engine is housed in a separate fireproof building. The shop, warehouse and office buildings are all of fireproof construction with modern equipment. The mine is operated with Sullivan short-wall chain mining machines and General Electric haulage and gathering locomotives. The construction work of this plant was in charge of D. A. Herbert, who is now general superintendent.

It is suggested that the fireboss, when looking for gas caps, should (1) employ the same lamp every day; (2) that the lamp—if correct percentages are aimed at—should be in exactly the same condition each time the test is made; (3) that the oil and wick and everything in connection with the lamp should be exactly the same at all times. The first condition may be easy to fulfill, but the second and third present some difficulties. The fireboss who gets over them should publish his experience for the benefit of the whole community.

A Portable Self-Rescuer

A portable rescue apparatus for emergency use in mine accidents has been placed on the market recently by the Draeger Oxygen Apparatus Co., of Pittsburgh, Penn. The apparatus weighs only 6½ lb., and can be carried slung over the shoulder or suspended from the neck. The oxygen supply is sufficient to furnish an abundance of air for a period of from 30 to 45 minutes.

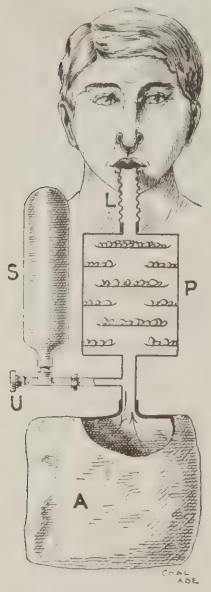


FIG. 1. SECTION OF BREATHING APPARATUS

The accompanying sectional drawing will give some idea of the operation of the apparatus. The oxygen passes from the oxygen cylinder *S* through the closing valve *U* into the breathing bag *A*. The first inhalation draws the air from the breathing bag through the potash cartridge *B*, and the flexible tube *L*. The exhaled air comes back through the tube *L* into the cartridge *B*. Here the nitrogen is freed from the carbon-dioxide, and, passing into the breathing bag *A*, absorbs sufficient oxygen and is again inhaled through the cartridge and the tube into the lungs.

When the oxygen supply becomes depleted, the air can be refreshed by quickly turning the closing valve *N*, admitting a new supply into the breathing bag.

In event of accident, the wearer opens the canvas cover, places the rubber mouth-piece firmly in his mouth, adjusts the nose slits, and then opens and closes the oxygen-cylinder valves. He is immediately supplied with an adequate amount of air.

As seen with breathing bag inflated, it reaches down below the waist line of the wearer and the apparatus appears somewhat cumbersome, but as shown in Fig. 2, which represents a man carrying the apparatus when not in use, it does not occupy much space and could be carried on the back entirely without annoyance. All that is necessary to put it into operation is to unbutton the canvas apron, place the rubber mouthpiece in the mouth, so that the flap sets firmly between the lips and gums. The teeth hold the small rubber lugs in place. The nose clip is next adjusted and the oxygen cylinder opened for a few seconds until the breathing bag is filled. Smoke goggles, if such have been supplied, can then be adjusted over the eyes.

FIG. 2. THE SELF RESCUER FOLDED UP AND STRUNG OVER THE NECK

The breathing bag should not be inflated with outside air before turning on the oxygen valve. By letting the inflation of the bag depend entirely on the presence of oxygen, its deflation will be evidence of the absorption of that oxygen as carbon dioxide in the potash cartridge. The oxygen valve is opened and closed intermittently, so as to keep the bag supplied with the right quantity of oxygen. Too much should not be used at one time or the pressure will be too high and exhalation will be difficult.

Of course, only fresh cartridges should be used. The potash will rattle when shaken so long as it is fresh. After it has lost its power of absorbing the impurities in the air, it will cease to rattle.

First-Aid Treatment for Fractured or Injured Pelvis

BY A. S. SNYDER*

It is always necessary to examine a fractured or severely injured pelvis in order to render first-aid intelligently; and in any case where there is doubt as to fracture, the injured should be treated as if fracture had occurred. It is also important to treat for shock, and some form of stimulant should be administered. When practicable, the patient should be well covered and warmth should be applied to the body.

In securing the injury, place a broad-fold bandage or two, if necessary, around the pelvis; tighten it up until the patient experiences the greatest degree of comfort and then tie it in place. This refers to triangular bandages, as they are generally the only material for that purpose on hand. It is better, however, to have long strips of muslin, from 6 to 8 in. wide, for injuries of this kind, and to secure them by pinning in about four places.

When it is necessary to transfer the injured from the stretcher to the ambulance cot, spread a blanket on the stretcher before placing the patient thereon, so that he may be lifted from the stretcher to the cot without danger of any further injury. In lifting the injured, it is important to keep the blanket well stretched, and, to insure this, three men should be employed on each side. Another man can remove the stretcher and place the ambulance cot beneath the patient, so that he may be lowered perpendicularly on to the cot. The same blanket may be used, in the same manner, in unloading the patent at the hospital.

Careful and gentle handling are all important.

Illinois State Mine Certificates

The State Mining Board of Illinois will hold a meeting at the State House, Springfield, commencing Monday, April 20, for the purpose of examining candidates applying for certificates as Mine Managers (First and Second Class), Mine Examiner, and Hoisting Engineer. Registration of candidates for these examinations will close at 5 p.m., Monday, Apr. 20, at the office of the Mining Board. The State Mining Board is composed of the following men: John Bohlander, president; James Forester, Thomas L. Jones, James Shaw and J. B. McKiernan.

It is possible to inclose all electrical conductors used in coal mines in substantial metallic outer coverings, and Robert Nelson says an appreciable step forward in the direction of greater security will be made when it is fully recognized that all electrical plants intended for use below ground should be so enclosed. This applies to light and to heavy apparatus, that is, to the cables and fittings for electric-lighting apparatus, and to all cables in conjunction with such apparatus.

*Instructor in first-aid and mine-rescue work, Berwind-White Coal Co., Windber, Penn.

Prevention of Coal-Dust Explosions

SYNOPSIS—The British authorities recommend a mixture of stone dust with the powdered coal of the mines, such that, on incineration, the ash left will weigh half as much as the sample taken. This amount will not assure absolute safety, for an explosion which has gained violence in far more favorable mixtures, will extend long distances in roadways strewn with stone dust in the proportion thus suggested.

An experiment conducted by the committee showed that the presence of incombustible dust decreases the inflammability of coal dust. The *relative* ignition temperature of a coal dust and of the same dust mixed with shale dust so that the mixture contained 20 per cent. of the latter, was 1005 deg. and 1095 deg., respectively. The committee states that the effect of an admixture of an incombustible dust with coal dust on the propagation of inflammation is also marked, and they tabulate the results of experiments in the Altofts gallery as follows:

TABLE SHOWING HOW INCOMBUSTIBLE DUST PREVENTS EXTENSION OF INFLAMMATION

Mixture Parts by Weight Coal Dust	Shale Dust	Mixture per Cu.Ft. of Air Space Oz.	Result
100	0	0.2	Flame propagated throughout the gallery
90	10	0.2	Flame traveled 110 ft. only
90	10	0.4	Flame propagated throughout the gallery
80	20	0.4	Flame traveled 80 ft. only
80	20	0.6	Flame propagated throughout the gallery
70	30	0.6	Flame traveled 63 ft. only
70	30	0.8	Flame propagated throughout the gallery
60	40	0.8	Flame traveled 16.5 ft. only
60	40	1.0	Flame propagated throughout the gallery
50	50	1.0	Evidence of flame in vicinity of cannon only.

The experiments show that the admixture of so small a quantity of incombustible dust as to form 10 per cent. only of the mixture greatly retards the development of an explosion. Thus comparative experiments with (1) pure coal dust and (2) coal dust containing 10 per cent. of shale dust, conditions being otherwise identical, showed:

TABLE SHOWING THAT PROPAGATION AND PRESSURE DEPEND ON PURITY OF DUST

	Mean Rate of Propagation of Flame, in Ft. per Sec.	Maximum Pressure Developed, Lb. per Sq.In.
Pure coal dust	1700	50.0
Coal dust containing 10 per cent. of shale dust.....	185	4.8

Dust Acts Like an Inert Gas

The admixture of an incombustible dust with the coal dust, it is explained, appears to act in the same way as the admixture of an inert gas with an explosive gas mixture; the incombustible dust, like the inert gas, takes up heat from the contiguous molecules, and, not being combustible itself, reduces the average temperature. If the temperature is sufficiently reduced the flame cannot be propagated.

The committee emphasize the fact that the "limiting mixture"—half coal dust and half incombustible dust—suggested as uninflammable by the above experiments, only holds for the conditions of the experiments, and for the means of ignition employed. A more violent means of ignition, such as they have obtained by starting the flame in a mixture of coal dust and air *per se*, may cause propagation of flame even under the adverse condition where inorganic and organic dusts are in equal proportion.

Anthracite Dust Will Extend an Explosion

It is suggested that in the propagation of flame along a large dust-strewn gallery, the dust from one bituminous coal can be regarded as of nearly equal sensitiveness with the dust from other bituminous coals. The dusts from anthracite coals are, as is well known, of a low degree of inflammability. It is difficult to *start* the general inflammation of a cloud of anthracite dust; but anthracite dust is quite capable of extending an explosion.

It is not essential to an explosion that coal dust be quite dry; on the contrary, coal with a considerable quantity of moisture in it may form a cloud of dust and be inflamed.

The behavior of coal dust varies with the method of ignition. For example, a large flame of burning gas, unaccompanied by any concussion or violent disturbance of the air, will fail to cause even pure coal dust to propagate flame for more than a limited distance, when the dust is simply deposited in the path of the flame. In order that a self-propagating inflammation of coal dust may be produced by such a flame, it is necessary that the dust should be in suspension in the air as a fairly dense cloud for a considerable distance.

When the flame is accompanied by concussion, as is the case with a blown-out or overcharged shot or an explosion of firedamp, it is no longer necessary for the coal dust to be previously in suspension in the air; but it must be so disposed in the region of the shot that the flame therefrom shall have every chance of igniting a considerable volume of dust-cloud raised by the concussion. In other words, the coal dust must be thick in the air before it can be fired.

Explosion Is Not Caused When Coal and Incombustible Dust Are in Equal Proportions

A mixture in equal proportions of coal and incombustible dust, lying close to the path of the discharge, did not give rise to a spreading inflammation when a charge of 24 oz. of blasting powder was fired from a cannon in the gallery. It is, therefore, unlikely that such a mixture lying on the floor or other surfaces in a mine would give a spreading inflammation when subjected to the flame of a blown-out shot from a similar charge.

A mixture in these proportions (1:1) is, however, capable of being raised and ignited by a pure coal-dust inflammation (started by means of a cannon shot), and the inflammation, so started, may then be propagated through such mixture.

Much More Inert Dust Needed for Extinction

Under the same conditions a mixture containing two parts by weight of incombustible dust to one of coal dust is capable of prolonging the flame of an inflammation started by black blasting powder shot in coal dust, and the flame may continue for a considerable distance

Note—Report of British Explosions in Mines Committee on experiments to determine the influence of incombustible dusts in preventing the inflammation of coal dust.

through such mixture before it dies out. Possibly such a mixture might propagate flame indefinitely if the zone of combustion were under still higher pressure. The committee's experiments have only dealt as yet with inflammations in the clear gallery open at one end and without artificial restrictions.

A slowly traveling inflammation, such as is produced when a ready-made dust cloud is ignited by a large jet of gas (unaccompanied by concussion) is at first capable of licking up coal dust deposited upon the surface of an incombustible dust and propagating itself for some distance until sufficient violence is developed to raise the incombustible dust also. This raising of the incombustible dust is more readily effected when a lighter or more buoyant dust, such as flue dust or fuller's earth, is employed, both coal and incombustible dust being raised in suspension together, and the flame soon dying down.

Explosions Not Always Instantly Checked by Inert Dust

A cloud of ignited coal dust may travel a considerable distance along a clear gallery free from coal or other dust. In many cases also the committee found that an ignition caused by the cannon and tube succeeded by 250 ft. of pure coal dust traveled 500 ft. along a gallery strewn with a 2 : 1 or even 3 : 1 mixture of incombustible dust and coal dust—the mixture of incombustible dust and coal being partly blown out of the gallery in front of the flame, and partly burned on mingling with the pure coal dust driven forward from the inflammation zone of pure coal dust.

When the coal dust forming the inflammation zone is previously diluted so as to contain 40 per cent. of incombustible dust, the inflammation is not propagated through a 2 : 1 mixture strewn in front of it along the gallery, since the mingling of the two mixtures cannot form a combustible cloud for any considerable distance.

Incombustible dust is more effective in preventing the ignition of coal dust than in checking an inflammation that has started. It should, therefore, be distributed uniformly throughout those galleries of the mine subject to the danger of coal-dust ignition, and if maintained in the proportion of between one and two parts by weight of incombustible dust to one of coal dust, the chances of such ignition taking place would be very small. Even a small proportion of incombustible dust (20 or 30 per cent. by weight) has a marked effect in checking an incipient inflammation.

Zonal Treatment Not Effective

The disposal of incombustible dust in zones or in easily disturbed masses concentrated in certain positions, leaving portions of the roads untreated, is, the committee thinks, not likely to be effective. In the case of mild inflammations, an incombustible dust that is readily raised and floats in the air has been found to be more effective than one which, owing to its shape or density, is less buoyant.

Shale dusts, or even heavier dusts, such as sand, are, however, effective when sufficient violence has been attained to raise them in suspension in the air.

As a provisional precaution till their experiments are more advanced, the committee makes the following suggestions: The experiments have clearly shown the great difficulty of initiating an explosion in a gallery where the coal dust has been mixed with an easily raised incombustible dust so that the mixture contained at least 50 per cent. of incombustible material. Hence, the committee is confident that the dust in a mine so treated would be relatively safe from ordinary ignitions, and consequently that the chance of a disastrous explosion would be greatly diminished.

Use at Least as Much Stone Dust as There Is Powdered Coal

It is true that such a mixture might not extinguish the fierce flame due to the explosion of a cloud of pure coal dust, or to an explosion of firedamp and air, either of which has gathered violence in its passage along a roadway—these conditions, and the effect of firedamp in the air have still to be tested. But a mixture containing 50 per cent. of incombustible matter may be raised in a cloud and brought into contact with a flame of equal or even greater intensity and volume than those ordinarily met with in a mine, such as might be produced by the ignition of a blower or an accumulation of firedamp, an accidental electric arc, or by a blownout black blasting-powder shot, without inflammation being propagated through it.

Since this admixture with 50 per cent. of incombustible matter, which can be carried out in a simple and practical way, confers on coal dust such power of resisting inflammation, it might be, in the committee's opinion, most usefully adopted now, even if further experiments lead to new developments, or other methods be found more efficient.

Approve of Stone Dust Being Used Instead of Water

They think, therefore, that, as an alternative to watering, the treatment of coal dust by an incombustible dust —so as to maintain an excess of incombustible matter in the mixed dust—might be adopted as fulfilling the requirements of the Coal Mines Act, 1911.

By section 62 (3) and (4) of that act, it is enacted that:

> The roof, floor and sides of the roads shall be systematically cleared so as to prevent coal dust from accumulating as far as practicable, and * * * * systematic steps, either by way of watering or otherwise * * * * shall be taken to prevent explosions of coal dust occurring or being carried along the roads.

Such a systematic step as is laid down in the above clause would be taken, in the committee's opinion, if the roads were treated with incombustible dust *provided* that the clearing of the roads required above and the treatment with incombustible dust were carried out in such a manner that at no time should such fine dust as was capable of being raised in suspension from the exposed surfaces of the roads contain less than such a quantity of incombustible matter as would make a mixture yielding on incineration at least 50 per cent. of ash.

Application Should Assure That There Is as Much Inert Gas as Powdered Coal Always and Everywhere

It should be clearly understood that in recommending this limit of 50 per cent. of ash, they are putting it forward provisionally and as a *minimum*.

The incineration test has been proposed by the committee to test the proportion of shales and other similar

forms of incombustible dusts. But it is not intended to condemn the use of other tests provided they yield trustworthy and equivalent results.

It is not possible to prescribe the quantity of incombustible dust to be applied or the periods of its application, since these will vary according to the conditions of each mine and of different parts of the same mine. But the *proportion* of incombustible to combustible matter in the dust—which is the main factor of security—can easily be tested.

It does not think it practicable to prescribe the methods by which incombustible dust should be applied. The best method would depend upon the circumstances and conditions of each mine; but the incombustible dust should be so applied as to free the timbers and higher ledges as far as practicable from coal dust, and to replace it by incombustible dust.

Inasmuch as in practice the incombustible dust will be applied at intervals, it is obvious that for some time after its application the roadways may contain a proportion of incombustible matter larger than that which the committee recommend as the minimum.

Suggestions for Testing

For the purpose of examination it is suggested that each sample should be collected not from one spot only, but from the dust deposited generally on the floor, roof and sides over some yards of roadway.

The several samples collected should be well mixed, and a portion sieved through a piece of metallic gauze (such as safety-lamp gauze) with a mesh of 28 to the linear inch; any dust that will not pass through such a sieve should be omitted from the determination.

Incineration Test Recommended as Safe and Simple, Not Scientific

For the purpose of the incineration test, a weighed quantity of the fine portions so separated should be brought to a red heat in an open vessel until it no longer loses weight. In this process all the natural ash in the coal is reckoned as incombustible dust, and on the other hand any combustible or volatile matter in the incombustible dust is reckoned as coal.

Shales usually contain a small quantity of carbonaceous matter, which is rightly reckoned as coal in the mixture, since it might act as fuel in a mine explosion; but shales always contain also a considerable quantity of incombustible volatile matter, mainly water, which is driven off at a red heat. It will be obvious that this incombustible volatile matter will afford a margin of safety, since in the method of evaluation recommended, such lost matter, although not contributing to make up the 50 per cent. of ash required, will really be effective in the quenching of inflammations in the mine.

For example, in a mixture of equal parts by weight of shale and coal dust used in the committee's experiments, they found on incineration 48 per cent. of ash. The coal contained 3.6 per cent. of ash, so that 50 per cent. of it contained 1.8 parts of ash. The shale lost 7.6 per cent. at a red heat, so that 50 parts lost 3.8 parts, and left 46.2 parts of ash:

	From Coal	From Shale		Total
Ash	1.8	46.2	=	48
Matter lost at red heat	48.2	3.8	=	52
Total	50.0	50.0		100

Consequently, this 50 per cent. mixture (equal parts by weight) yielded a total of 48 per cent. of ash, i.e., would have been returned as falling two parts below the proposed minimum requirement, although in reality the mixture contained over 50 per cent. of incombustible matter. The committee have borne in mind this margin of safety in recommending the minimum of 50 per cent. of ash on incineration.

Effect of Gas on Problem

A considerable difficulty arises with regard to practical application of such a suggestion to the working faces of a mine and to the roads immediately adjoining. This is a matter on which the committee think it desirable that both further experimental data and practical experience should be acquired.

It is possible that the presence of small percentages of firedamp may influence the inflammability of mixtures of coal and of incombustible dusts. But if this is found to be the case it would not affect the suggestion for the treatment of the roadways, since in the main haulage roads, where the coal dust is most dangerous, the amount of gas is usually small.

Experiments upon the effects of watering and other methods of rendering coal dust harmless have yet to be made, and some other matters bearing upon the coal-dust question have yet to be elucidated.

Briquette Production Valued at More Than Million Dollars

Coal briquettes to the amount of 181,859 short tons, valued at the plants at $1,007,327, were manufactured in 1913, according to Edward W. Parker, of the United States Geological Survey. The figures for 1913 show a decrease of 17 per cent. in the tonnage of briquettes manufactured, but an increase of over 5½ per cent. in value over the figures for 1912. Seventeen briquetting plants were in operation during the year, eight in the Eastern States, five in the Central States, and four on the Pacific Coast. Seven of these plants used anthracite culm or "fines," five used bituminous or semi-bituminous coal, two used carbon residue from oil-gas works, and the others used mixed coals. Coal-tar pitch is the principal binder employed, eight plants using it. Patented binders were used at five plants.

If the future of this infant relative of the coal-mining industry is to be judged by the record of 1913, the judgment should be based on the increase in value rather than on the decrease in plants and in tonnage. Briquetted fuel in the United States is essentially a domestic fuel, for which there was a slackened demand in 1913, owing to the exceptional mildness of the winter of 1912-13, and of last November and December. In consequence the consumption of briquettes for domestic purposes, like that of raw fuel, was generally less throughout the United States in 1913 than in either 1911 or 1912. An exception to this decrease is to be noted on the Pacific coast, where the number of operating plants increased from three to four, and the production in 1913 was exactly double that of 1912, with a gain in value of somewhat larger proportion.

Marketing Conditions, New Orleans

By Paul Wooton*

SYNOPSIS—With the near approach of the opening of the Panama Canal, the coal situation at New Orleans is attracting general interest. Development of an all-water route from the Alabama fields is one of the most important factors so far. Local consumption has tripled in the past decade and even greater increases are anticipated in the future.

New Orleans has to thank the same flood waters, that have menaced so many of Louisiana's fertile acres this year, for the largest supply of coal ever brought to the city. And while the river craft are piling up the reserves of Pittsburgh coal at one end of the harbor, bulging gondolas are being shunted in train lots onto the chutes at the other, where the Alabama supply is overtaxing storage room.

Rapid Growth of the Local Trade

That there should ever be a heavy demand for coal at this port was unthought of a few years ago. Big cotton crops, general increases in shipping, the growing importance of the fruit trade and of the passenger travel to Panama, Central America and the West Indies, in addition to the greater number of steam plants ashore, are some of the causes which have more than tripled the coal consumption of this port in less than a decade. In the light of this growth and in view of the opening of the Panama Canal, there is not a coal man in New Orleans who does not take a roseate view of the future.

Alabama interests, feeling that they are handicapped by the lack of water transportation, are spending $1,500,000 to make possible the landing of their product independent of the rail lines. In order to get Alabama coal to New Orleans by water it has been necessary to dredge the old Lake Borgne Canal, clean out portions of three rivers, build an extensive loading station and construct specially built barges. Further expenditure has been made in equipping trams for loading the barges in Alabama. The barges will be loaded at stations along the Black Warrior River. The Tombigbee and Alabama Rivers will be followed to Mobile, thence across Mobile Bay and Mississippi Sound to Lake Borgne and to the opening of the canal, which has its terminus at Violet, La., on the river eleven miles below New Orleans.

In order to supply the barges for this trade at the least cost it was found necessary to equip a shipyard at Violet. Here the fifteen barges, which will open the trade, have been built. Each barge is 240 ft. long with a 32-ft. beam. They are equipped with twin screws and producer-gas engines; they have a rated speed of eight miles an hour at sea, a carrying capacity of 100 tons and draw six feet of water.

Empties Starting up the Mississippi for Pittsburgh

A power lighter with a handling tower of 500 tons per hour capacity has been launched in the river at Violet and every facility has been installed to insure rapid and economical handling. The locks, shops and all machinery are operated electrically. A turning basin 300 ft. long has been dredged.

Coaling Ocean-Going Vessels in the Harbor at New Orleans

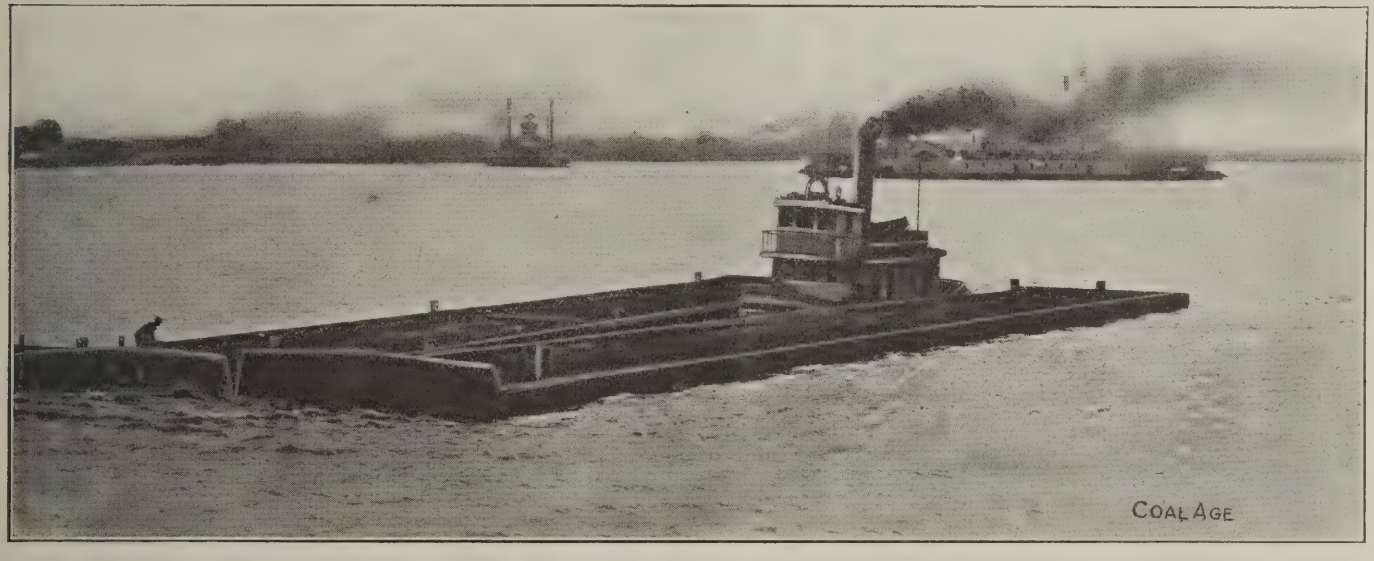
Alabama Coal vs. the Pittsburgh Product

As the mines along the Warrior River are developed, the tonnage will be increased. This development will be rapid as the location and continuity of the seams has been proved by diamond drilling. For this reason, the ship yard will continue turning out barges as rapidly as possible. It is predicted that the demand for coal in New

*319 South Cortez St., New Orleans, La.

Orleans will be great enough within the next two or three years to justify the use of hundreds of barges in this trade.

While many claims are made by rival interests, it is the opinion of disinterested students of the situation that Alabama coal can never entirely shut out the Pittsburgh product. On the other hand, it has been proved beyond a doubt that the monopoly once enjoyed by the Pittsburgh dealers can never again be established.



It is practically certain that there will be lower quotations made as soon as Alabama coal begins moving in by the all-water route. This will be met by the other interests without great sacrifice and any probability of a price war is discounted. At present, Pittsburgh coal is trimmed into bunkers on ships at $3.75 a ton. Alabama coal is furnished at $3.25. Pittsburgh coal sells ashore at $3 and the same ratio in price prevails. This represents the general difference in the efficiency of the two kinds of coal.

The retail trade in New Orleans is much lighter than in any other large American city, due to the mild winters. Open grates, for the most part, are used to heat private dwellings and two tons is the amount of coal consumed by the average family during the winter. As there are so many small orders, the cost of delivery is high, which accounts for the abnormal retail price of $6 per ton. Liberal discounts are made from this price, however, where the order is large enough to justify it.

Preparations, made by several oil companies for handling fuel oil to ships here, never have been considered seriously by the coal interests. Any undercurrent of nervousness that may have been felt has been dissipated by the rapid rise in fuel-oil prices in the past year.

New Orleans coal dealers are not depending entirely on the growth of shipping at the opening of the Panama Canal to bring the heavy increase in business that they expect. The export trade to Latin America has assumed proportions that show the increasing importance of this field. As New Orleans is closer to the east coast of Central America and to the entire western coast of South America than any other American port, the city expects to be one of the foremost providers for the commercial wants of this vast territory. Mining operations and other industries are extensive and with the increasing developments the demand for coal has advanced from a negligible amount ten years ago to interesting figures today.

Plans for the increase of facilities in New Orleans are in evidence on the properties of several of the coal companies. Additional room for storage is being provided and heavy expenditures are being made for handling machinery. That New Orleans is to become the greatest coal-exporting port in the country is a view held by many.

HANDLING COAL BARGES WITH A TUG IN THE NEW ORLEANS HARBOR

The First "Strip Pit" Sold

The sale of the first strip-pit or opencut mine to be sold in Kansas by the operators, took place Mar. 20. Also it was the first pit opened in Kansas, and it has been understood that it was the most profitable one.

The pit in question was that of the Miller-Durkee Coal Co., Scammon, Kan. Dan Miller, president of the company and superintendent of the pit, and his son, T. H. Miller, vice-president and assistant superintendent, sold their shares to W. W. Patterson, of Pittsburg, Kan. The latter is a coal operator of 15 years' experience. He will superintend the pit. Eighty acres of coal land went with the shovel and pit.

The Millers will rest for a few months and then, it is understood generally, they will become active operators again, probably in the opencut work, as they possess more than 100 acres of fine coal.

Dan Miller introduced the first steam shovel into the Kansas field to strip the covering from coal. He was the sort of pioneer who didn't hesitate because of his discouraging advisors. He was so successful in a short time that other men—Durkee and Pratt—brought in a shovel. Today his pit—the one he sold—is the "daddy" of 35 great pits in Crawford and Cherokee counties. In the four years which Miller has operated the pit, he has uncovered about 55 acres from 15 to 28 ft. deep.

Officers in the new company are: A. H. Skidmore, Columbus, Kan., president; W. W. Patterson, vice-president; and S. L. Walker, Columbus, Kan., secretary-treasurer.

Gasoline Locomotives in a Pennsylvania Mine

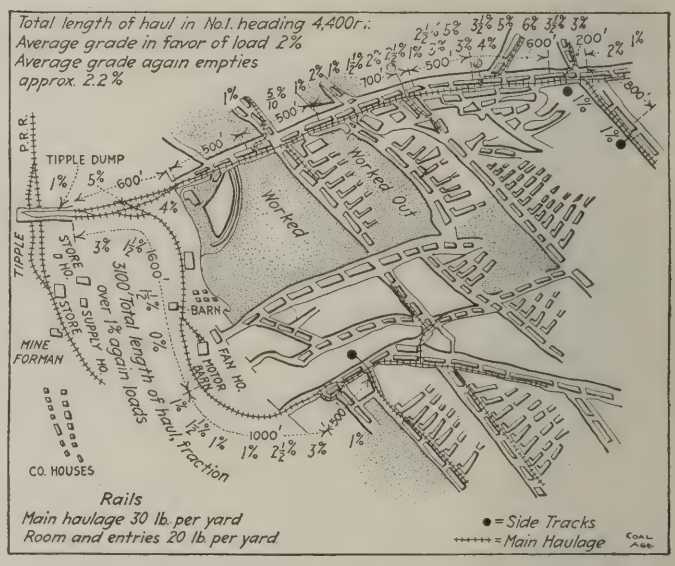
SYNOPSIS—A comparative study of the cost of gasoline-locomotive haulage versus mule haulage in proportion to production at the Hagevo operation of the Shade Coal Mining Co.

The Shade Coal Mining Co. has approximately 1000 acres of seam "A," 5-ft. coal and seam "B" Miller vein, 3-ft. 8-in. coal at Hagevo, Somerset County, Penn.

The operation is complete, with uptodate equipment throughout. The tipple is 285 ft. long, equipped with a Phillips Mine- and Mill-Supply cross-over dump with kick-back for empties, and has a maximum tipple capacity of 3000 tons daily. A Robinson 300-r.p.m., 65,000-cu.ft. fan has been installed, being driven by a 20-hp. Fairbanks gasoline engine.

The coal is hauled in one hundred and eighty-five 1000-lb. mine cars, having a capacity of 2500 lb., all of these cars being equipped with plain bearings. The outside and main-entry track consists of 30-lb. per yd. rail, and back of the first gathering point in the mine, the rail weighs 20 lb. per yd. The minimum radius of the curves is approximately 30 feet.

The first Milwaukee gasoline locomotive was put in operation, Oct. 12, 1911, and was an M-35, 7-ton, 36-in. gage locomotive. It has a vertical, 4-cylinder, 4-cycle engine, 6-in. bore and 6-in. stroke, which develops 35 hp. at 800 r.p.m. The drive wheels are 21 in. in diameter, wheel base 48 in., length overall 140 in., width overall 49 in., height 49 in. The transmission is of the inclosed type with two speeds of four and eight miles per hour in each direction. The gears run in oil and are changed by means of jaw clutches with all gears in mesh. The locomotive has sanders on all four wheels, and is provided with an equalized hand brake, operating all the wheels, and a deodorizing tank for absorbing the engine exhaust.



The second locomotive was put in service Mar. 22, 1913, and is a duplicate of the first machine. Before

Motor Hauling Empty Cars from Tipple into No. 1 Mine

Haulage Layout at the Shade Coal Co.'s Mine

Mine Tipple, Also Showing Loaded and Empty Tracks

Before Locomotives Were Installed, Mules Were Used to Pull the Trips

the installation of the second motor, in October, 1912, 12,544 tons were handled by the first motor, but in view of the development of the work and tonnage proposed eventually at Mine No. 3, the second locomotive was installed.

Mule haulage was used before the gasoline locomotives were introduced and at that time the following conditions prevailed:

OPERATING CONDITIONS

Length of haul one way, 2640 ft.
Maximum grade in favor of loads, 2½ per cent.
Maximum grade against empties, 5 per cent.
Tonnage per month of 24 working days, 9600 tons.

COST OF MULE HAULAGE

10 mules to handle tonnage @ 60c. per day	$6.00
Above day rate includes feed, harness and shoeing expenses.	
Eight drivers @ $2.25 per day	18.00
Investment in 10 mules @ $200 is $2000. Assuming the average life of a mule is 5 years, this gives a 20 per cent. depreciation per year, 24 working days per month, the cost for depreciation per day will be	1.38
Interest on investment at 6 per cent. per annum, per day	0.41
Mule haulage cost per day	$25.79
Total mule haulage cost per month of 24 working days	618.96
Mule haulage cost, per ton	0.064
Mule haulage cost per ton mile traveled by loads	0.128

GATHERING COST USING MULES AT MINE NO. 1

Tonnage per month of 24 working days, 9000 tons		
3 mules for gathering @ 60c. per day		$1.80
Three drivers @ $2.50 per day		7.50
Mule depreciation		0.417
Interest on investment at 6 per cent. per annum, per day		0.125
Total gathering expense per day		$9.842
Total gathering expense per month		$236.208
Gathering expense per ton		0.0262

MAIN ENTRY GASOLINE HAULAGE AT MINE NO. 1

Length of haul, one way, 4400 ft.		
Maximum grade in favor of loads, 6 per cent.		
Average grade in favor of loads, 2 per cent.		
Maximum grade against empties, 5 per cent.		
Average grade against empties, 2.2 per cent.		
Tonnage per month of 24 working days, 9000 tons		
Motorman for 24 days @ $2.75	$66.00	
Triprider for 24 days @ $2.75	66.00	
Total labor		$132.00
384 gal. of gasoline per month @ 15½c	$59.52	
24 gal. engine oil per month @ 30c	7.20	
6 gal. black oil per month @ 15c	0.90	
6 lb. cup grease per month @ 15c	0.90	
Waste per month	1.00	
Total supplies		69.52
Repairs:		
Material	$28.95	
Labor	6.86	
Total repairs		35.81
Depreciation on locomotive at 10 per cent. per annum, per mo.		29.16
Interest on locomotive investment at 6 per cent. per annum, per mo.		17.50
Total operating cost per month		$283.99
Operating cost per day	$11.83	
Operating cost per ton	0.0315	
Operating cost per ton mile traveled by loads	0.0379	

GATHERING COST USING MULES AT MINE NO. 3

Tonnage per month of 24 working days, 3500 tons		
1 mule required for gathering at 60c. per day		$0.60
1 driver required per day		2.40
Mule depreciation per day		0.138
Interest on investment at 6 per cent. per annum, per day		0.0416
Total gathering expense per day		$3.1796
Gathering expense per month	$76.308	
Gathering expense per ton	0.0218	

MAIN ENTRY GASOLINE HAULAGE AT MINE NO. 3

Length of haul, one way, 3100 ft.		
Motorman for 24 days at $3 per day		$72.00
Trip rider for 24 days at $2.75 per day		66.00
Labor		$138.00
120 gal. gasoline per month @ 15½c	$18.60	
4 gal. engine oil per month @ 30c	1.20	
2 gal. black oil per month @ 15c	0.30	
2 lb. cup grease per month @ 15c	0.30	
2 lb. waste per month @ 15c	0.30	
Total supplies		20.70
Repairs:		
Material	$28.95	
Labor	6.86	
Total repairs		35.81
Depreciation on locomotive @ 10 per cent. per annum, per month		29.16
Interest on locomotive investment @ 6 per cent. per annum, per month		17.50
Total operating cost per month		$241.17
Operating cost per day	$10.04	
Operating cost per ton	0.0691	
Operating cost per ton mile	0.1173	

Mine No. 3 is under development, and the motor, as well as the gathering mule and driver, are not working to exceed 40 per cent. of the time. The gasoline consumption, and the amount of sand used, varies with the weather. The gasoline consumption runs from 4 to 7 gal. per day, bad weather causing more wheel slippage and a higher engine speed, and, thereby, increasing gasoline fuel consumption.

SUMMARY BASED ON EXPERIENCE IN MINE NO. 1

Mule haulage cost per ton	$0.064
Gasoline haulage per ton	0.0315
Saving per ton	0.0325
Mule haulage cost per ton mile	0.128
Gasoline haulage per ton mile	0.0379
Saving per ton mile	0.0901

Government Control of Lake Traffic

In line with the movement against all business done on a large scale, is the investigation of the management of the ore-carrying fleets on the Great Lakes. No longer does an owner control a single boat. In the process of evolution, the ownerships have consolidated so that one company or firm now manages a dozen, or a score of vessels.

Rates Are as Low as Half a Mil per Ton Mile

That the new régime has brought down the cost of lake transportation is considered by these investigators as of small account when set beside the fact that in recent years the contract rates for carrying ore have shown a good deal of uniformity. Those who have followed the statistics of lake freights for years know that 40 years ago a charter from Marquette at $5 a ton was not uncommon; that 30 years ago $2 a ton was paid, while 20 years ago the contract rate from Marquette was commonly $1 a ton.

The inquisitors' report omits entirely any such comparisons as the above, which shows how amazing has been the cheapening of lake transportation. Nowhere else on the globe is there a haul that approaches in cheapness the cost of bringing a ton of iron ore nearly 1000 miles from the docks on Lake Superior to the unloading docks on Lake Erie.

The latter-day rates cited by the committee figure out from 1-15 to 1-20c. per ton per mile, yet the only comment of the investigators is that despite these favorable rates the dividends of the leading lake carriers for five years show that the business was a profitable one!

No violation of the Sherman act is alleged in this concentration of lake-vessel interests; nor is any act detrimental to the public interest. Contrary to intimations lately given from the Department of Commerce that the smaller competitive unit in industry is more efficient than large consolidations, the committee finds great improvements in lake transportation, as strong, well managed companies have become the rule. There is no proposal to separate these companies into their elements, as with the large corporations the government is now prosecuting. The great capacity shown for bettering transportation service on the lakes is held to mean also great capacity to exercise the hurtful powers of monopoly; hence, we come to the inevitable proposal of government regulation. For good or for ill, such a development in lake transportation seems not far ahead.—*The Iron Age.*

A Study of Mine Fatalities

Twenty-seven hundred and eighty-five men were killed in the coal mines of the United States during the year 1913, according to a report just issued by the United States Bureau of Mines. This is an increase of 425 deaths over the previous year 1912, and gives a fatality rate of 3.82 in every 1000 men employed as compared with 3.27 in 1912. Six thousand more men were employed in 1913 and the increase in production was between 30,000,000 and 40,000,000 tons.

Dr. Joseph A. Holmes, director of the bureau, in commenting upon the record for the year said:

An examination of the statistics develops the disappointing fact that in our coal-mining operations during 1913, there were killed 425 more men than during 1912. This is an increase of 18 per cent. in fatal accidents, with an increase of only about 8 per cent. in coal production.

We can find little comfort in the suggestion that this increase may in part be accounted for by the occurrence during 1913 of four large mine explosions. Furthermore, while the total deaths from mine explosions was 213 greater in 1913 than in 1912, the number of explosions in which more than five men were killed was only seven as compared with ten explosions in 1912. In fact, the statistics show an increase in fatalities during 1913 from all the underground causes except mine fires and surface accidents.

Some progress has been made, however, in the safety movement as shown by the statistics for the last eight years. In the four years ending Dec. 31, 1909, the average death rate was 3.97 for each 1000 men employed. In the last four years the rate was 3.68. Comparing deaths with production of coal, the number of fatalities for each one million tons mined during the four years ending Dec. 31, 1909, was 5.99, as compared with 5.11 for the four years ending Dec. 31, 1913. These latter figures indicate a general gain of 17 per cent. for safety during the last four years over the four years preceding. But this progress has been small as compared to that which the country will demand during the next few years.

It is unfortunate that the safety inquiries and investigations by the National Government, upon which so much depends, have lagged so far behind the needs of the industry and public demand. It is hoped that this situation may be remedied at an early date.

The states in which the greatest number of deaths occurred are as follows: Pennsylvania, 1227; West Virginia, 337; New Mexico, 272; Ohio, 165; Illinois, 164; Alabama, 124, and Colorado, 108.

The four biggest explosions of the year and the number of deaths at each were: Apr. 23, Cincinnati mine, Finleyville, Penn., 96; Oct. 22, Stag Canon Mine No. 2, Dawson, N. M., 263; Nov. 18, Acton Mine No. 2, Acton, Ala., 24; Dec. 16, Vulcan Mine, New Castle, Colo., 37

Gravity Railroad Yards

The use of gravity or hump switching for the classification of freight cars, in order to group together those for certain destinations or with certain commodities, is increasing in the case of large and busy yards, and is one of the subjects discussed in the report of the Committee on Yards and Terminals of the American Railway and Engineering Association.

One of the most important elements in the design of a gravity yard is the determination of the rate of grade for the descending or accelerating grades from the summit of the hump, upon which the cars acquire the momentum which carries them along the classification ladder and into the classification tracks. It is difficult to determine this with any degree of exactness since conditions vary in different yards, and factors of location and traffic affect the car movement. In colder districts and where the cars are mainly empty, the grades must be somewhat steeper than in warmer climates and where the cars are mainly loaded.

The grades must be sufficiently steep to insure that each car will run readily to any part of the classification tracks (under control of the car rider or brakeman), but not steep enough to result in injury to the cars and loading due to the moving cars striking the standing cars with undue force. Some officials consider that there is more damage of this kind in gravity yards than in flat yards, but this is not general experience or opinion, and there is no good reason why it should be the case.

The arrangement of grades previously submitted by the committee and adopted by the Association as "recommended practice" (with the track scale on the grade) is as follows:

1. Where cars are largely empty: 2% for 60 ft. and 4% for 50 ft., followed by 1% on the ladder and 0.5% through the classification tracks.

2. Where cars are largely loaded: the same grades, but the 4% grade may be shortened (to not less than 25 ft.), and the two following grades should be at least 0.8% and 0.4%, respectively.

3. The grade over the scale not to exceed 2%.

The committee made inquiry as to proposed changes in the above, but most of the replies were to the effect that no changes were desired. One reply, however, suggested rates of grades as shown by the accompanying table, the length of incline being 300 ft. in each case, succeeded by 1% grade along ladder and turnouts.

SUGGESTED GRADES AT UPPER END OF YARD

	Starting	Over Scale	Accelerating
Loaded cars; with scale	3% for 35 ft.	0.5% for 50 ft.	2.5% for 215 ft.
Loaded cars; no scale	3% for 100 ft.	.....	1.5% for 200 ft.
Light cars; with scale	3% for 40 ft.	0.5% for 50 ft.	3 % for 210 ft.
Light cars; no scale	3% for 200 ft.	.....	1.5% for 100 ft.

The principal feature of this arrangement is in reducing the grade over the scale, instead of putting the scale on the 2% grade at the summit. The idea is to check the speed slightly in passing over the scale, the steeper grade above the scale being necessary to start and space the cars. This reduction of grade is followed in many gravity yards.—*Engineering News.*

The Champion Mines of Kansas

By Barry Scobee*

The "champion" coal mine in Kansas, in point of production for 1913, was the Devlin-Miller mine (see Fig. 1) of the Cherokee-Pittsburg Coal & Mining Co. It produced 207,182 tons, according to figures in the office of State Mine Inspector Francis Keegan, in Pittsburg. The mine is seven miles north of Pittsburg in the "north field" of the extreme southeastern Kansas district. Compared to the old "south field," this territory is relatively new.

The southern coal field, which lies mostly in Cherokee County, south of Pittsburg, is practically worked out. This refers to Weir City, Scammon, Chicopee and Mineral, towns well known a few years ago for their big production. However, there still exists in these localities an upper seam of coal, which is being removed by steam shovels in the open-cut process, and which soon will be worked, it is believed, by the longwall method.

*Pittsburg, Kan.

FIG. 1. MINE OF THE CHEROKEE-PITTSBURG COAL AND MINING CO., PITTSBURG, KAN.

Of the four mines in southeastern Kansas which led in production in 1913, and which are here described, only one, "Central 42," is in the south field.

The Devlin-Miller mine is 180 ft. deep, and works a seam averaging 38 to 40 in. in thickness. The coal is mined by the room-and-pillar method, with solid shooting. (This thickness and method are descriptive of practically all mines in the district.) Last year the mine worked 260 days and employed, on an average, 305 men.

The next mine, in point of production, was No. 15 (see Fig. 2) of the Western Coal & Mining Co., which worked 228 days, with an average of 252 men, and took out 174,000 tons of coal. This mine is 200 ft. deep, and is situated near Franklin.

The third mine in the series was the Nevius-Coulter (see Fig. 4), at Radley, with 171,641 tons to its credit. It worked 290 days with an average of 175 men. It is about 175 ft. deep.

Mine No. 42 (see Fig. 3) of the Central Coal & Coke Co., three miles southwest of Scammon, was the fourth, producing 171,339 tons. This shaft is only 60 ft. deep.

In all of these mines the method of firing shots is by lighting the fuse with a torch. A recent report of the state mine inspector showed that 20 shotfirers had been killed in this district in the last three winters, and that deaths usually were due to "windy" shots. Most of these deaths have taken place in the north field, where the mines are deeper and dryer than in the south field.

FIG. 2. MINE NO. 15 OF THE WESTERN COAL AND MINING CO., FRANKLIN, KAN.

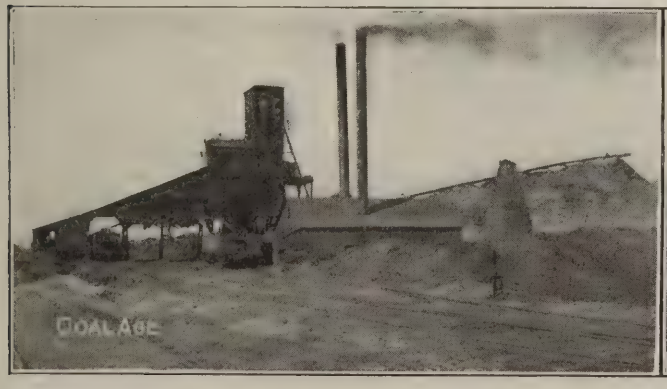

FIG. 3. MINE NO. 42 OF THE CENTRAL COAL AND COKE CO., SCAMMON, KAN.

German Coke Ovens

In a paper before the North of England Institute of Mining Engineers, on Feb. 14, 1 '14, Leo Dorey Ford describes a coke-oven plant he had an opportunity of visiting in Germany. The coke ovens consist of two batteries of 50 ovens each, of the Otto Hilgenstock under-burning regenerative type. The oven chambers are 33 ft. long, 7 ft. high, and have a width of 17½ in. at the pushing-engine side, and of 21½ in. at the discharging side. The charge of an oven is 8 tons of uncompressed small coal, which is hand filled through three charging holes, the coal being brought in 1-ton cars from a central hopper situated between the two batteries.

For the heating of the ovens, the gas from the by-product plant is conveyed through a central main running underneath the entire battery, two small branch pipes being taken off the main directly under the walls of each oven, and connected to nine Bunsen burners which burn in vertical flues in each wall. Each wall is divided into nine separate vertical flues, each of which is divided some distance above the nine burners into two smaller flues. The eighteen main flues are grouped in four sections, the first and the third of which communicate through the second and fourth with a regenerator-flue by way of small openings leading into a horizontal flue running under half of the sole of, say, the left-hand oven. The second and fourth sections communicate in their turn through the first and third sections with another regenerator flue by way of small openings leading into a horizontal flue running under half of the sole of the right-hand oven. These ways form alternately the burnt-gas outlets and the hot-air inlets, according to which set of burners is in use.

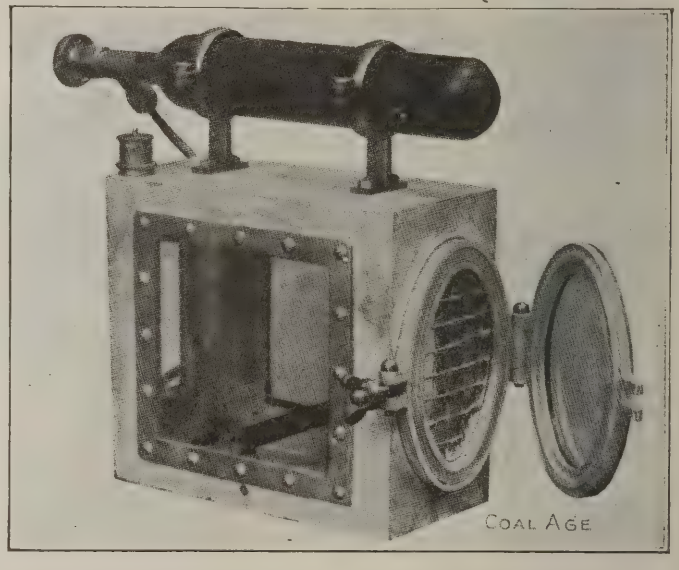
The ovens change over every half hour. Taking one wall, for the first half hour, the burners in the first and third sections only are alight, and the burnt gases, after rising to the top of the wall, descend by the dead flues in the second and fourth sections, respectively, passing out through the small openings into the flue under half of the sole of the left-hand oven and so into the dead regenerator flue and up the chimney.

The hot air for ignition comes to the burners of the first and third sections from the live regenerator flue on the other side of the battery by way of the flue under the half of the sole of the right-hand oven with which these sections are in communication.

At the end of half an hour the burners in the first and third sections are extinguished by cutting off the gas and air, which are then admitted to the burners of the second and fourth sections. The burnt gases now, after ascending the flues of these sections, descend the flues of the first and third sections, respectively, and go to the regenerator flue by what was the air-inlet passage for the first half hour. The air for ignition is now admitted from the hot regenerators by what was in the first half hour the burnt-gas outlet.

The two regenerator flues are connected by a common way to the waste-gas chimney and at their junction is a two-way valve, which allows of the closing or opening of either way at will, this automatically opening or closing the other way.

The air burned with the gas is taken from the passage-ways under the ovens, and is regulated by means of sliding shutters placed along the side of the passages.



The gas taps of the small branch pipes, and also the air shutters, are all connected, and are opened or closed together. The changing of the ovens can thus be effected in a few minutes.

The time taken for coking varies from 28 to 29 hours, each oven giving a 75 per cent. yield, or six tons of good, hard coke. Of the 50 ovens in each battery, 42 are discharged in 24 hours, and give an output of about 500 tons of coke per day.

The yield of gas may be reckoned as 11,300 cu.ft. per ton of dry coke, or some 5,651,000 cu.ft. per 24 hours. Of the total gas, 50 per cent. is burned under the coke ovens, the surplus being divided in the following rough proportion: Illuminating gas, 12 to 20 per cent.; power gas, 12 to 18 per cent.; and gas for heating boilers, 15 to 25 per cent. These figures, of course, vary considerably, according to temporary requirements.

Cage for Animal Air Tests

Canaries and mice are, as is well known, frequently used in exploration work after an explosion or mine fire to detect the presence of carbon monoxide. Any cage will serve for their transportation either in or outside the mine, but the use of a canary or mouse is entirely lost, if it is once rendered unconscious and if it can only be

CAGE FOR ANIMAL USED IN TESTING FOR CARBON MONOXIDE

revived by taking it for a long time to the surface or to a part of the mine where the air is fresh and brisk.

It is necessary to have a cage which can be rendered air tight and a supply of oxygen which will revive the bird or other animal immediately, presuming it has not been exposed to too deadly an atmosphere. In this way men traveling into places which are dangerously full of noxious gases can retreat and still have an animal in condition to give new indications on a later advance.

The cage is made of metal and has a glass in the back and sides. In front is an oval window with a coarse wire netting and the net is covered when desired by a tight-fitting door. Above the cage is an oxygen cylinder, the contents of which can be gradually discharged into the cage. When the door is closed, a little oxygen admitted to the now air-tight receptacle will soon purify the air

within. Excess pressure is prevented by the escape vent on the top and rear of the receptacle.

The small oxygen cylinder acts as a handle for the cage. As soon as the canary or other animal is overcome it can be revived even if the rescue men have a long way to return in a vitiated atmosphere or find it advisable to go forward, in their helmets, regardless of the indications, leaving the canary behind. This "Animal Air Tester" is made by Siebe, Gorman & Co., of London, England, their agent in America being H. N. Elmer, 1140 Monadnock Block, Chicago, Ill.

Text Book on Safety

An illustrated textbook, principally for the benefit of foreign mine workers who cannot speak English, is being prepared for publication under the auspices of the Young Men's Christian Association workers in the mining districts of West Virginia. The views in the little book will show the mining of bituminous coals at every stage: First, how the work should be done, and second, how it should not be done; the wrong way involving danger and the right way insuring safety.

Some of the pictures that will go to make up this text book have already been shown on the screen at gatherings of foreign mine workers, and they have been explained through interpreters. It is found that this pictorial method is more effectual than any number of printed or spoken warnings.

In recent years, since the English-speaking mine workers began to be supplanted by the immigrants from southern and eastern Europe, the larger companies have undertaken systematic education of their employees. The rules and regulations for safety are emphasized above everything else, and the photographic scheme is simply the latest way to "drive home" these rules and regulations. The official reports of the state inspectors show that most of the accidents are the result of disobedience of rules, either through ignorance or carelessness.

The textbook is so arranged that the pages facing one another will show the way to invite accident and the way to prevent it. The books will soon be ready for distribution by the Y. M. C. A. workers and they will be used generally in educational work throughout the coal region.

Promise and Performance

By Berton Braley

Written expressly for Coal Age.

"When we get on top," said Mike to Bill,
"I'll spill you around like a pail of swill,
I'll smash your face and I'll bust your jaw
So even your wife or your paw and maw,
Won't know the cripple I'll make of you,
I'll mash you into an Irish stew!
I'd do it NOW, but the Boss is 'round
And he hates this fighting underground,
But I sure will make you take a flop,
When we get on top!"

"When we get on top," said Bill to Mike,
"You can start right in as soon's you like,
You'll find me ready to meet you there
And I'll certainly smear you around the place
Till there's nothing left but your hide and hair
And maybe a piece of your ugly face!
You've swelled around here long enough
And I'm the guy who will call your bluff!
I'll show you the kind of a gink I am
When I break your ribs with a right-hand slam,
And hammer your mug till you holler, 'Stop!'
When we get on top!"

They mouthed and muttered and cursed and swore,
They threatened each other with death—or more,
They went way back into history
And roasted each other's family,
And they kept right on in their wrath and rage
As they mounted up on the crowded cage,
But when they stepped into broad daylight
And the gang all followed to see the fight
They both looked sheepish and half afraid
And in spite of the gory threats they'd made,
They both hiked homeward without a stop
When they got on top!

Who's Who in Coal Mining

George R. Wood

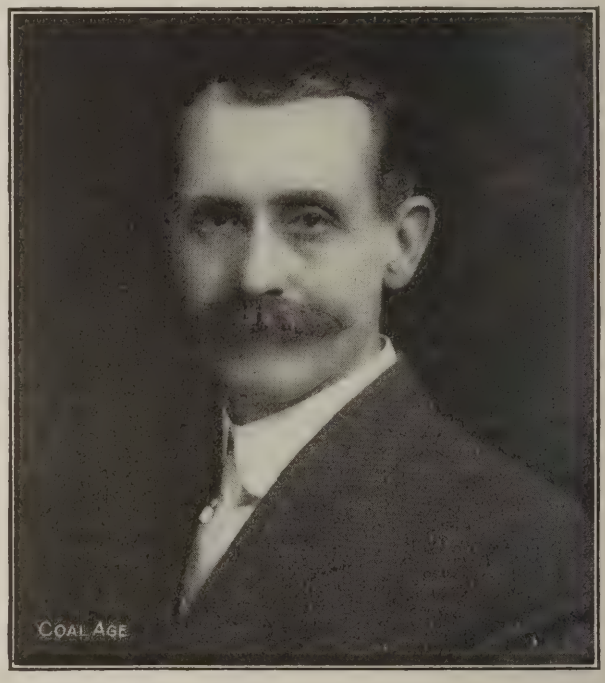
George R. Wood, at present electrical and mechanical engineer for the Berwind-White Coal Mining Co., and allied companies, was born at Martin's Ferry, Ohio in 1872. Mr. Wood's ancestors were among the early settlers in Ohio, Absalom Martin, his grandfather, having located on a tract of land granted him by the British Governor Dunmore, of Virginia, for service in the Indian wars. Another, Joel Wood, a Quaker and Abolitionist, prior to the Civil War operated a station on the "Underground Railroad" for runaway slaves.

Mr. Wood received his technical education at the Rose Polytechnic Institute, Terre Haute, Ind., graduating from that institution with the degree B. S. in Mechanical Engineering, 1892, and B. S. in Civil Engineering, 1893.

After leaving college he was in the employ of the General Electric Co., leaving them in 1899 to accept a position with the Pittsburgh Coal Co. He remained with this latter corporation until 1902, when he engaged in the practice of consulting electrical engineering, which work he continued until 1912, at which time he became chief electrical and mechanical engineer for the Berwind interests.

Mr. Wood is a member of the Racquet and Manufacturers' Clubs of Philadelphia, University Club of Pittsburgh, American Institute of Electrical Engineers, American Society of Mechanical Engineers, American Institute of Mining Engineers, American Mining Congress, Franklin Institute and Engineering Society of Western Pennsylvania.

GEORGE R. WOOD



Oscar Cartlidge

Oscar Cartlidge, manager of the Illinois State Mine Rescue Station, is a native of Illinois, having been born in that state at Shelbyville, Aug. 12, 1870. His education was received in the common schools of Illinois.

Mr. Cartlidge started life as a miner, soon advancing to the position of mine foreman for the Raymond Coal Co. of Illinois. Later he held a like position with the West Virginia Coal Co., the Johnson City Coal Co. and the Benton Coal Co., all of Illinois. After this, he was foreman for the Kansas and Texas Coal Co. in Arkansas. His next position was as superintendent of the Egyptian Coal Co., of Illinois, after which he again allied himself with the Johnson City Coal Co., filling the position of assistant superintendent.

Taking up engineering work, Mr. Cartlidge was then appointed mine engineer for the Benton Coal Co., and the Hart-Williams Coal Co., both of Illinois; after this he was made county mine inspector, Franklin County, Illinois, and then state inspector of mines for that state. At the present time, he is manager of the Illinois mine-rescue stations. Under his management, these stations have done a most acceptable work in the actual recovery of mines after fires and in training men for rescue work. It may be added that Mr. Cartlidge has contributed some valuable articles to technical literature.

Oscar Cartlidge is a member of the American Institute of Mining Engineers, American Mine Safety Association, Mine Inspectors' Institute of America and the Illinois Mining Institute.

OSCAR CARTLIDGE

Editorials

The Lockout

We are not a little disappointed that in face of a national business depression, the operators in central Pennsylvania and Ohio have declared for a lockout. It is true that there is but little demand for coal and that all the fuel which is needed can be secured by the purchase of coal from competing districts. But the suspension of work is hard to describe otherwise than as unfortunate and ill-advised.

In Pennsylvania particularly there was no need for such action. The operators and miners both desired the renewal of the scale with the exception that the miners sought the abolition of car pushing, and a closed shop. Any one acquainted with the conditions realizes that the operators could not grant the former concession demanded without a reduction in the wage scale because the competition of the Pittsburgh district, already severe, would thrust the operators of District No. 2 out of the market. This the miners would have seen sooner or later.

Meanwhile they were willing to continue working during the discussion and what could possibly be gained by a lockout? Clearly the miners stand in a position to gain public sympathy by their much more rational behavior and the operators cannot but place themselves in a laughable position in that they have condemned the Union for preparing for a strike, whereas they were themselves contemplating a lockout.

The Ohio situation is not so simple as that in central Pennsylvania. The new anti-screen law goes into effect May 20. By that time the agreement must be made or the operators must close their mines down, for if they try to establish a run-of-mine scale not suited to the miners, the latter will refuse to work, while if they continue at the old lump-coal scale, they will be subject to a suit with uncertainty as to the outcome should the law be proved of force. They would be liable to have to pay their men at the order of the court a differential which would bankrupt the companies.

This perhaps is the reason why they are anxious to make a settlement without delay. They desire to be idle when coal can be bought without trouble and markets can be kept. No one knows how business may be later in the year.

But let us again urge that the only way to obtain reasonable unions is by being reasonable operators. The only way to get public approval is by abandoning the tactics which the people disapprove, and however crooked the public may be in its own business, it has a book of ethics written for the mine operator far more lengthy, detailed and stringent than Deuteronomy and the Twelve Tables.

We do not blame the "dear public" if they condemn the operators for doing those same things for which the mine owners have condemned the Union. If it is wrong, when a settlement is in sight, for the Union to hold the strike club over the operator even when there is no contract, it is at least equally wrong for the mine owner to try to drive the miner into line with an actually consummated lockout.

The country needs that as much work shall be supplied to workingmen as possible. This can only be assured by dividing what work is needed over the whole country as evenly as may be. This will give everyone some work and some purchasing power and everyone will be buying something. Times will then not be so bad as if large parts of the country are idle where the workers can buy nothing and other parts are more busy, but the men are hoarding against the possibility of bad times. For it is the purchases of the workingmen which give us prosperity.

Every operator who can, should work. The men will ultimately yield in the districts where there are disputes We are disposed to believe that the fields made idle by lockouts are likely to lose business in their desire to inflict a loss on their mine workers. This year should be one of victory for the operators, because of the depressed business conditions. Let them not mar their reputation by unreasonableness.

For the miners are likely to model themselves after their employers, and stubborn, suspicious, disaffected men are usually found to be the employees of unreasonable, uncharitable and embittered mine owners.

Is the Ohio Screen Law Constitutional?

The Ohio Coal Operators' Association have finally instituted proceedings to test the validity of the new legislation governing mining operations in that state. The initial move is in the form of a suit, filed in the United States District Court, restraining the State of Ohio from putting the new screen-coal law into effect. If possible, it will take the form of an injunction in the name of the Ohio Coal Operators' Association, but in event of such a move not proving legal, the suit will be transferred to some one of the concerns doing business in Ohio, but incorporated and having its principal offices outside of the state.

More than a year ago, the people of Ohio voted upon some articles in the Constitution, in which a certain conservation clause was embodied. It now appears that this was written into the constitution in the form of a "joker" in order to legalize the mine-run law, which followed it later. The advocates of this latter measure, in order to avoid any possibility whatever, of evasion, overstepped the legal prerogatives of a state constitution, and it now develops that the rights of contract have been so abrogated that the law is not constitutional.

That part of the constitution legalizing the conservation measures, also provides that the Supreme Court of of the state can only declare an act invalid when six of the seven judges concur in the opinion. The coal operators are, therefore, overcoming this phase of the situation by entering suit in the United States courts—a move

which is to be commended in view of the fact that Hugh McNichols, who was lieutenant governor under Cox, during the time the screen-law was enacted, has since been appointed Chief Justice of the Ohio Supreme Court.

With these proceedings now underway, and negotiations pending for another conference with the Ohio miners, the situation there has materially clarified. A more optimistic feeling prevails generally among the operators, and there is a general belief in all quarters that the present negotiations of the operators will be successfully consummated in time for the local producers to participate in the Lake trade.

Conservation

We are disposed to think that serious attention should be given to the legislation about to be passed on the Western coal lands. And here we pause, because after all is that legislation likely to find place on the statute books at present? Little has been heard of the need of it since Franklin K. Lane declared its necessity, and only George Otis Smith seems to have remembered how essential is a new law to the progress of the West.

Pressure should be brought to bear or the matter will be allowed to drift in favor of less important measures which are backed by more importunate interests and which appeal more forcibly to the imagination of the public.

We wish to draw attention to one form of conservation—that of human effort. What shall be done with land containing coal at a depth of 1000 or 2000 ft. below the surface, which has been approached by the workings of some corporation and left because it is a part of the unprocurable domain of the United States?

The point of approach is secured and the coal has been tested along the property line far better than any drilling could test it. The coal can be delivered to a point on the surface suited for railroad delivery. On the other hand, if the old mine is abandoned, the deeper coal is shut off and must be developed by a deep shaft at much expense. The coal to be exploited must be proved first to be worthy of the expenditure not merely on the border line, but throughout an extensive area because a large sum of money has now to be expended before any return can be anticipated, whereas in the event of the extension of an old mine the extra expense would be negligible.

And possibly in many cases not only is the depth of the shaft a disadvantage, but the location for a tipple and railroad tracks may also be bad.

The worst feature is the fact that the operator must feel assured from the first that the coal is not only of chemical quality suited for profitable merchandizing and of necessary thickness for remunerative mining, but must also know that it is of sufficient strength to make it possible for him to mine it at all. Some of the Western coal is of an extremely friable character.

In some places the coal not only is abandoned at a depth of 1000 to 2000 ft., but dips further to several thousands of feet. Would it not be best to let the companies mining the coal go on down with the seam as far as they can do so profitably and with due conservation?

If, being placed under careful supervision, they extract a large percentage of the coal, it seems that the royalty charge should be small. The coal if left would be lost for generations and when extracted by a shaft would be as expensive as that produced in Great Britain, Germany and Belgium.

Conservation is saving for future generations, and we must be careful that when we lock up coal wealth for our children, that we do not seal it in a safe so inviolate that the cost of recovery will be greater than the value of the fuel. It would, indeed, be better to give it away for the use of the present consumer than to cache it in a place where no hand could ever reach it.

Straightforwardness

In the last issue of COAL AGE, a contributor discussed, in a frank manner, the straightforwardness that the public have a right to expect of men intrusted with the important duties of mine inspection. Attention was called to the fact that the "court of public opinion" is far more powerful than the law itself to eradicate evil, lessen danger and reduce the accident list. It was claimed that the "hush" policy is wrong in principle, inasmuch as it obstructs the formation of correct public opinion.

We desire, briefly, to indorse these sentiments in their general application to mine-inspection work, with the simple modification that *statements made or information given must concern the parties thus informed.*

The mine inspector is, unquestionably, the servant of the people. He is intrusted with a sacred duty, involving the public health and life. We grant that occasion may not always demand the publication of facts and information in the knowledge of the inspector, and that to avoid unduly exciting public opinion in a matter wholly in control by the inspector, he may, in the absence of immediate danger to others, refrain from giving publicity to some facts in hand. It is a broad principle of equity, however, that *the people have a right to facts concerning their own health and safety, the moment a situation passes beyond the control of the duly authorized officer of law.*

We opine that a mine inspector, in the conscientious performance of his duty and obligation to the people, may withhold any and all information and facts in his knowledge, so long as his silence will assist the ends of justice and does not tend to greater loss and danger to life and property.

There are, on the other hand, just as truly, facts and information in the knowledge of the inspector, that concern only the companies mining the coal, and do not affect public life or property. To divulge such facts and information would be as great a breach of trust on the part of an inspector as to keep silence on matters requiring publicity in order to properly mold public opinion. Truly it may be said, in a broad and general sense, that *the court of public opinion is a court of last appeals, and is incapable of doing an injustice, because it is so constituted that the equal rights of all men, ultimately, find there like recognition.*

Much good would result if coal companies would make compulsory a weekly meeting of superintendents, firebosses, mine foremen, master mechanics, stable bosses, hoisting engineers, etc., of each plant for the discussion of working conditions, general operation and all other topics vital to the work in their charge. The plan has been adopted with success by several companies.

Legal Department

Damages for Wrongfully Mining Coal

By A. L. H. Street*

SYNOPSIS—Recovery is measurable by value of the coal at the mine mouth, less the cost of production, unless the taking was willful, in which case no allowance is made for expense in mining and removal. Qualifications of the rule noted.

When one mines coal on the land of another and removes it, his liability in damages is limited to the value of the coal in place, on it appearing that he had no title to it, provided he acts in good faith. But, if he acts in willful or reckless disregard of the rights of the true owner, he becomes legally liable for the full value of the coal taken, without deduction for expense incurred in mining and removing the same. And when it is shown that coal has been wrongfully taken from land, the courts will presume that the taking was intentional, in the absence of proof to the contrary. These rules, which were announced by the United States Circuit Court of Appeals for the Eighth Circuit, in the case of Central Coal & Coke Co. vs. Penny, 173 Federal Reporter 340, have been substantially followed by all the higher courts of the country. But, although the Illinois Supreme Court recognizes the rule that, in case of an innocent trespass, the aggrieved landowner's damages should be measured by the value of the coal at the mouth of the pit, less the cost of carrying it there, with allowance for mining, that tribunal holds that punitive damages are properly assessed when it is established that the trespass was willful. (Illinois & St. Louis Railroad & Fuel Co. vs. Ogle, 92 Illinois Supreme Court Reports 353.)

Important Court Decisions Cited

In computing the damages which must be paid for an innocent trespass, the trespasser is not entitled to an allowance for cost of "knocking down" the coal in mining it. (Alabama Supreme Court, Ivy Coal & Coke Co. vs. Alabama Coal & Coke Co., 33 Southern Reporter 547.)

The Iowa statute which makes a coal operator liable in double damages for taking coal from adjoining lands without the owner's permission, creates a double liability for injury done the surface in commission of a trespass. (Iowa Supreme Court, Mier vs. Phillips Fuel Co., 107 Northwestern Reporter 621.)

An operator, in mining coal near the boundary line of an adjoining landowner, is under a legal duty to make surveys to prevent encroachment upon the latter, and to keep accurate accounts of coal mined near the line; and, if he fails to do so, evidence as to the quantity of coal removed from the adjoining land will be construed most strongly against him. (Tennessee Supreme Court, Coal Creek Mining & Manufacturing Co. vs. Moses, 15 Lea Reports 300.) In this case it was decided that the measure of damages for an unintended trespass is the value of the coal in place before the trespass, plus any incidental damage to the land by the taking of the coal or the mode of taking. This same rule was applied by the same court in a case where the trespass was committed under an honest dispute as to title. Ross vs. Scott, 15 Lea Reports 479.) Injury to the land, as an element of recoverable damage, was recognized by the Pennsylvania Supreme Court in the case of Forsyth vs. Wells, 41 Pennsylvania State Reports 291.

Rights and Liabilities of Third Parties

In a Colorado case, in which the land from which the coal was improperly removed was under a mining lease given to a third person, it was decided by the Supreme Court that the lessee properly joined with the landowner in a suit to compel the trespasser to account for the coal taken. (United Coal Co. vs. Cañon City Coal Co., 48 Pacific Reporter 1045.) But in similar circumstances it was held by the Missouri Supreme Court that a lessee who had never attempted to operate under his lease, and who manifested no purpose to do so, was not a necessary party to the suit; the landowner being entitled to recover the full value of the coal wrongfully taken by defendant. (Lyons vs. Central Coal & Coke Co., 144 Southwestern Reporter 503.) And the Kansas Supreme Court has decided that a lessee, who had the exclusive right to conduct mining operations upon a tract of land for a stated period, could not recover more than nominal damages from one who wrongfully removed a part of the underlying coal, where it appeared that the lessee could not have reached the particular coal during the term of his lease. (Chappel vs. Foster, 123 Pacific Reporter 870.) In a suit by a landowner for wrongful removal of his coal, it was held by the Missouri Supreme Court to be no valid defense that defendant had settled with a third person, who held a lease on the land, for the value of the coal taken. (Austin vs. Huntsville Coal & Mfg. Co., 72 Missouri Reports 535.) Where one who owned one tract of land and the surface of an adjoining tract purported to lease the right of mining under the latter tract, the Illinois Supreme Court held him responsible for the value of coal taken by the lessee, at the mouth of the pit, less the cost of elevation. (Donovan vs. Consolidated Coal Co., of St. Louis, 58 Northeastern Reporter 290.)

Early Maryland decisions support the rule that if the trespasser, by bad mining or otherwise, leaves the remaining coal in such situation that it cannot be profitably mined, or makes its production more expensive, the landowner can have this injury considered in the assessment of his damages. (Barton Coal Co. vs. Cox, 39 Maryland Reports 1, and Franklin Coal Co. vs. McMillan, 49 Maryland Reports 549.)

Assumption of Risk of Injury on Ladder—An adult employee being presumed to know every fact which a person of ordinary prudence for his own safety would observe, an engineer at a coal elevator must be deemed to have assumed the risk of being injured through breaking of a defective ladder, if he knew it was worn and old. (Indiana Appellate Court, Beard vs. Goulding, 103 Northeastern Reporter 875.)

*Attorney-at-law, St. Paul, Minn.

Lockout in Central Pennsylvania

A large majority of the members of the Association of Bituminous Coal Operators of Central Pennsylvania, District No. 2, representing over 85 per cent. of the total tonnage of the Association, met in Philadelphia, April 11.

The following operators were present:

Allegheny River Mining Co., Buffalo & Susquehanna Coal & Coke Co., Cascade Coal & Coke Co., Cherry Tree Coal Co., Clark Brothers Coal Mining Co., Clearfield Bituminous Coal Corporation, Clearfield Colliery Co., Duncan-Spangler Coal Co., Empire Coal Mining Co., Falls Creek Coal Co., Jefferson Coal Co., Jefferson & Clearfield Coal & Iron Co., Kettle Creek Coal Mining Co., Madeira, Hill & Co., Inc., Martin's Branch Coal Mining Co., Moshannon Coal Mining Co., Northwestern Mining & Exchange Co., Peale, Peacock & Kerr, Inc., Pennsylvania Coal & Coke Corporation, Pioneer Coal Co., Portage Coal Mining Co., Potts Run Land Co., Punxsutawney Coal Mining Co., Rich Hill Coal Co., Rochester & Pittsburgh Coal & Iron Co., Seneca Coal Mining Co., Shawmut Mining Co., Trout Run Coal Mining Co., Watkins Coal Co., and other operators.

The following preamble and resolution was unanimously adopted:

Whereas, the representatives of the United Mine Workers of America and the representatives of the Bituminous Coal Operators Association met in joint conference of their respective scale committees at Du Bois on the 3d of March, 1914, to negotiate a wage scale to cover the period of two years next ensuing after Apr. 1, 1914:

And whereas, the conference, after several days' deliberation, adjourned to meet in Philadelphia on the 23d day of March:

And whereas, the Operator's scale committee offered to renew, for a period of two years, the scale of wages and conditions covered by the scale agreement signed in April, 1912, which is on a higher basis than that paid in competitive districts;

And whereas, after two weeks of continuous negotiation, the representatives of the United Mine Workers of America declined said offer;

And whereas, the representatives of the United Mine Workers of America refused to consider a wage contract that did not carry with it a provision that placed upon the operators the impossible burden of pushing cars, together with closed shop and other conditions which entail a prohibitive expense, the result of which would place the cost of producing coal in the Central District of Pennsylvania beyond the plane of competition;

And whereas, the United Mine Workers of America admitted their inability and refused to make a definite contract until after the policy announced at Chicago by their policy committee had been finally submitted to a referendum vote and ratified;

And whereas, many operators of the Central District of Pennsylvania find that in offering work and in attempting to run their mines at the present time, the majority of the men refuse to work and in fact are on strike;

And whereas, if the operators could succeed in worknig their mines in whole or in part, they would be working without a contract with the United Mine Workers of America, and consequently upon an unknown wage basis, and, therefore, would be left in the position of not knowing what their coal would cost them f.o.b. cars;

And whereas, the operators, because of the foregoing facts and in the absence of a definite contract with the United Mine Workers of America find themselves in a position where they are unable to promise deliveries, either as to time or amount, and thereby are prevented from entering into the usual annual contracts;

Now, therefore, be it resolved that in view of the foregoing facts and the attitude of the United Mine Workers of America, that we, the operators, today here associated, find it impossible to operate our mines until such time as the United Mine Workers of America, District No. 2, find themselves with authority and willingness to enter into a contract that renews for a further period of two years the wage-scale agreement, which expired Mar. 31, 1914;

Resolved, that the foregoing preambles and resolution be posted at the mines of the operators herein assembled as notice to their employees that it will be impossible to operate their respective mines after Saturday, Apr. 11, 1914, until an agreement has been reached.

The action taken was not by the association members, but by the individual operators who were in favor of shutting down.

Under the by-laws of the association, it requires a two-thirds vote of the entire membership to order a shut-down. At the meeting of the association where action was taken, there were 46 members present of a total of 60. It required a vote of 40 to pass the resolution for a suspension. It was lost by vote of 39 to 7, just lacking one vote to make the shut-down effective as a resolution of the body as a whole.

The sentiment was almost unanimous that a shut-down should be established, the only difference of opinion being that it was not wise to do so while the miners were powerless to make a scale agreement, full powers being withheld from them, until after the referendum vote of the Policy Committee's report has been taken and counted. This vote was taken on the 14th and will doubtless be counted by the 22d.

Had the vote of the association been taken on the advisability of a shut-down to begin after the 22d, or on May 1, if a new scale agreement were not effective by that date, it seems likely that the vote to suspend would have been adopted practically unanimously.

Two West Virginia Mines Have Made New Records

To have operated coal mines ten years or more and in all that time to have but one fatal accident, is a record that few operators can come anywhere near equaling. That is what has been done, however, at two West Virginia mines, according to the state records. One of these mines is that at Logan, W. Va., of which H. S. Gay is general manager, and the other that of the Columbus Iron & Steel Co., at Marting, W. Va., of which W. M. Gilly is superintendent.

The Gay mine has been in operation for a decade and during that time it has produced 805,000 tons. Only one death has occurred, and that was due to carelessness on the part of the man who lost his life.

So far as the records show, the highest tonnage per fatality in this country belongs to the Mine No. 1 of the Columbus Iron & Steel Co., at Marting, W. Va. This mine has been operated for 13 years and in that time it has produced 1,816,583 tons of coal. The records of the Federal Bureau of Mines and of the several state bureaus, do not show any coal mine in the country where the tonnage for each death has been higher. The facts show that if the victim had obeyed the orders of his mine foreman he also would not have been killed.

Both Mr. Gay and Mr. Gilly declare that the good records of their mines are, in no small measure, due to the care with which the miners have obeyed the state laws and the company rules and regulations governing the operations.

Mr. Gay has made a careful study of working conditions for the company at Logan, and he has been one of the leaders of the safety-first movement in that section. Col. J. G. Battelle and J. H. Frantz, president and vice-president of the Columbus Iron & Steel Co., have always insisted upon the principle of safety-first.

Discussion By Readers

Safety or Refuge Chambers in Mines

Letter No. 2—I read with much interest Charlton Dixon's remarks relative to establishing "safety" or "refuge chambers" in mines, with the idea of providing a means of escape from the deadly afterdamp of explosions, by those who have survived the blast, COAL AGE, Mar. 21, p. 498.

I am sorry to say that this suggestion does not appeal to me as altogether practicable, for more reasons than one. In extensive mines, to be available, many such chambers would be required; and as the development of the mine progressed the location of many of these would be inconvenient. In deep mines the expense of boring holes to these several chambers would be considerable. Since no one can foretell the origin or path of an explosion, which may or may not occur, the proper location of such chambers would not be easy to determine. Too often the path of the explosion would cut off the survivors from reaching such places of refuge.

Though much thought and attention have been given to the study of the causes and prevention of mine explosions, and much valuable knowledge has been acquired, explosions still occur, and, at times, we are tempted to think that these dread occurrences are beyond our control and power to prevent. In view of this fact we may ask: Are mine officials, generally, making use of the knowledge thus gained? Knowing that both gas and dust or either are capable of explosion, we ask further: Is every effort being made to remove these dangerous elements from the mines, and adopt such precautions as the use of permissible explosives, clay tamping, the employment of practical shotfirers, the humidifying of the air current with steam from the exhaust of the pump, spraying or sprinkling the roadways, testing the effectiveness of stone dust to prevent the spread of a local explosion and other well known means and methods?

Too often these precautions are disregarded; the mine becomes excessively dry and the dust is allowed to accumulate everywhere. Mines generating gas and, at times, those subject to frequent outbursts of gas continue to operate on open lights or mixed lights. It causes no surprise that explosions continue to occur, when one considers the flagrant disregard of simple necessary precautions that are well known but too often ignored.

We must all acknowledge that many good suggestions are made in respect to greater safety that are not sufficiently tried out in practice. Knowledge without practice is about equivalent to no knowledge at all. It is not so much what we know as what we do that counts for safety; we may know very much and do very little. If mine officials would make a judicious use of the suggestions made and put forth every effort to remove or render harmless elements known to invite explosion, great mine disasters would be less frequent. In dealing with the yellow-fever epidemic in the South, the Government pursued a wise policy in removing the cause by destroying the mosquito, instead of erecting hospitals and compounding remedies to cure the disease contracted.

Let us, in like manner, make every effort to remove the cause of mine disasters, and the need for safety chambers and other such "after aids" will soon vanish. If the same thought and attention were given to the prevention of disasters, that is now being given to the training of rescue corps and first-aid work, the result would be a more rigid discipline in the mine and a more persistent practice of the known means of safety.

JOHN ROSE,
District Mine Inspector.

Dayton, Tenn.

The Certificate Law

Letter No. 27—Referring to the interesting discussion concerning the mine foreman's certificate, there is one point that, if brought out in previous letters, has escaped my notice. I refer to the ability of the mine foreman to handle men. All the technical education and certificates in the world will not make a man a successful foreman unless he has this essential qualification.

I know an experienced educated man who holds a certificate and, as far as theoretical requirements are concerned, is one of the most competent men in the business; but, as a mine foreman, this man is an absolute failure, because he lacks tact and the ability to get along with his men. It is clear this is a qualification not revealed by the examination, and yet one that must be possessed in full measure by the man who hopes to make a success as a mine foreman.

Other men, again, have no judgment in the hiring of men. The foreman has nothing to guide him in the selection of his men but his knowledge of human nature, which is intuitive, and which some men possess more than others. A group of, perhaps, a dozen men, wait at the top of the shaft for the mine foreman's appearance from below. He has not places for all and must use his best judgment in selecting the most efficient workers and avoiding troublemakers, which are the pests of all mining camps. The mine foreman who lacks this insight into human nature soon fills his mine with a class of men who cause him endless worry and trouble. In the selection of men, the mine foreman should bear in mind the fact that although all men were created free and equal, no two are alike. The foreman must learn to study his men. A frank, open countenance is often a more valuable index of efficiency than a pair of brawny shoulders. Such countenances can be recognized in all races and nationalities.

Again, many a foreman is indifferent to the best interests of the work and will allow personal prejudice, like or dislike, to blind him to the virtues or shortcomings of the men in his charge. Such a foreman will often retain a lazy, inefficient fellow whom he happens to like, and find cause to let a hard-working, industrious man go because he does not like his manner. Men should be judged by

their work, and prejudice should not be allowed to control the judgment of a good foreman.

It must be allowed, however, that in these days of unions, it is not always possible to weed out the inefficient, careless workmen; but when work slackens in the summer a good foreman will not lose the opportunity thus offered to let such men go first. It is my belief that this lack of judgment on the part of the foreman, in the hiring of his men, is more often the cause of failure than any other one thing. Some men, it must be acknowledged, can never acquire the habits that others possess naturally. The question presents itself: Can an examination be devised that will determine whether or not the applicant or candidate for a mine foreman's certificate possesses this supreme qualification?

MINE SUPERINTENDENT.

————, Wyo.

Fan Ventilation

Referring again to my previous inquiry, COAL AGE, Feb. 7, p. 258, I am still of the opinion that the answer given to Mr. Hopkins' question, COAL AGE, Jan. 24, p. 180, may prove misleading, owing to the fact that Mr. Hopkins does not give sufficient data in stating his question. His proposition is to install a second fan on the left side of the mine, the present fan being located on the right side of the mine but not furnishing sufficient air for the ventilation of the entire mine.

Mr. Hopkins states that both of these fans will blow air into the mine by separate air courses, the one on the right and the other on the left side of the mine, the two air currents uniting at a point about a mile from the mouth of the mine and using the same return airway for this distance. He does not give the distance between the fan now in use and the location of the proposed fan; nor does he state the size of either fan, the quantity of air in circulation, or the water-gage readings.

In my inquiry, Feb. 7, I suggested that we assume that the present circulation, under the conditions described by Mr. Hopkins, in a level seam, is 80,000 cu.ft. of air per min., passing under a water gage of 3.5 in. and produced by a 12-ft. fan. I assumed, further, that the resistance of the return airway is equivalent to a 1.5-in. water gage, and asked how much would the circulation in the mine be increased if a 6-ft. Stine fan was now installed at the back entrance 1¾ miles from the present fan, assuming that this second fan was capable of producing 20,000 cu.ft. per min. against a 1-in. water gage.

This is a practical question, as there are 12.5-ft. fans installed at mines in this vicinity, which are producing 78,000 cu.ft. per min. against a 3.8-in. water gage, and 76,000 cu.ft. per min. against a 3.5-in. water gage. I may say that, under the conditions described, I would not consider it practical to install a small disk fan, as suggested.

CONSTANT READER.

Punxsutawney, Penn.

[We quite agree with our correspondent in his conclusions; but must insist, as we stated before, COAL AGE, Feb. 7, p. 258, in answer to this inquiry, that Constant Reader has assumed conditions not involved or suggested in the previous question of Mr. Hopkins.

Mr. Hopkins clearly states that both fans are to operate as blowers, ventilating separate sections of the mine but using a single return airway for a distance of a mile. Constant Reader wants to install a 6-ft. Stine fan, which is a disk fan, at a "back opening" 1¾ miles distant from the first fan. There may be some doubt as to this proposed arrangement; but, from the statement, it would naturally be supposed that the 6-ft. disk fan is to be installed at the return opening, and is to operate as an exhaust fan, the distance between the two fans being 1¾ miles. It is not clear, however, what is meant here by the "return airway." It is impossible to state how much, if any, the circulation in the mine would be increased by the installation of this fan.

In this connection, we would draw attention to a similar question, COAL AGE, Mar. 28, p. 539, which suggests installing a 6-ft. disk fan to ventilate a portion of a mine requiring more air. The present circulation, in this mine, is 78,000 cu.ft. per min., passing under a 3.4-in. water gage. This question clearly states that both fans will use the same return airway for a distance of 1 mile, but does not speak of a "back opening."

In answer to this last question (p. 539), we have assumed that both fans are operated as blowers. These fans, as in Mr. Hopkins' case, are thus assumed to work in parallel on two separate sections of the mine, using a common return air course; but, as stated in answer to each of these questions, it will be necessary to regulate or balance the two circulations. On the other hand, we understand the proposition of Constant Reader to refer to a tandem system of ventilation, the one fan blowing and the other exhausting, which has reference to the second fan acting as a "booster." The success of such a system will depend on two principal conditions, as previously stated (p. 259), namely, a possible shortening of the distance of air travel; and a possible condition of dead air in a portion of the workings, owing to leaky stoppings or dispersion of the air current in the mine and possible escape through other openings.—ED.]

The Mine Foreman

I was greatly interested in the article by Mr. Srodes, entitled "A Plea for the Mine Foreman," COAL AGE, Mar. 14, p. 458, inasmuch as I have long viewed the subject from the same point of compass as Mr. Srodes and can endorse all that he has said.

I feel sure that there is not a competent mine foreman in the state of West Virginia who does not feel the need of protection from some source. The state mining law gives him no protection but makes him responsible for the safe operation of the mine, requiring many things of him in his official capacity that he has no power to perform.

As far as the operation of the mine is concerned, that, in almost every case, is in the hands of the superintendent or manager, who, though he regards the mine foreman as a mere timekeeper, blames him for any mishap or accident that may occur in and around the mine.

Although the mine foreman is not permitted to choose, much less to dictate the manner in which the work should be done, and the means and methods employed are not such as he would adopt, he is held accountable for any undue increase in the cost of operation. The expense sheet may grow under the protest of the foreman, who desires certain changes in order to reduce the cost of operation which, however, the superintendent in charge

does not regard favorably, because of the necessary outlay required to make such changes.

The superintendent is often too far removed from the actual work underground to fully realize and appreciate the need of what the mine foreman recommends. Under these conditions, it is easy to see that there is too often a lack of coöperation between the office and the underground work. As a result, not infrequently, the office decides that it is necessary to change the mine foreman; and the latter is notified, as I have known to be the case, Saturday night that there would be another man to take his place Monday morning. No one will say that this is good business or right. It is, nevertheless, one of the hardships the mine foreman must endure.

Because the mine foreman is the man in direct charge and responsible for the performance of the work, the law, in many states, requires that he must pass a rigid examination to prove his competency to assume that position. The superintendent is not required to pass such an examination, but is the one who practically controls and directs the work. The mine foreman must spend much time and money to prepare himself for examination. He must continue to spend time and money for books and mining papers that will enable him to keep in touch with the best means and methods of mining. Notwithstanding this, as Mr. Srodes has stated, the pay of the mine foreman is inadequate to enable him to maintain the standard required.

The mine foreman must have practical experience. The most successful foremen are those who have worked their way from trapper boy up to that position, stimulated by the ambition to become foreman of the mine. When, at last, he realizes this hope, he finds that his authority and usefulness are limited while his responsibilities have increased. Before, he regarded only his own safety, now he is held responsible for the safety of every man in the mine, besides being blamed for any financial loss arising from the carrying out of plans made in the office, and which prove ill suited to conditions existing in the mine.

The foregoing are facts with which every mine foreman is well acquainted. The question is: "What can be done to lighten the burdens of the mine foreman? Is it not a case similar to that of "taxation without representation?" He is expected to carry out plans that his practical judgment pronounces difficult or wholly impossible without loss, for which he will be blamed. Let this question be carefully considered and discussed, in the hope that suggestions may be made that will be practical and helpful.

MINE FOREMAN.

———, W. Va.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

PROPORTIONATE DIVISION OF AIR

Every large and well managed mine is, now, divided into two or more separate ventilation districts. The natural division of the air current between these several districts is not generally in proportion to their respective needs.

The longer entries, working more men and requiring the most air for their ventilation are the ones that have the greater resisting power, and, as a result, receive a lesser proportion of the air, in natural division; while, on the other hand, the shorter air courses where fewer men are working and less air is required, have a smaller resisting power and naturally pass the larger quantity of air.

To Regulate the Air—In order to overcome these natural conditions, in mine ventilation, and divide the main air current so as to give each district of the mine the required proportion of air, it is necessary to employ some means that will produce this result.

Two methods have been used to divide the air proportionately; they are as follows:

1. The flow of air is obstructed in those airways that take naturally more than the desired proportion.

2. The power on the air, at the month of each split, is proportioned to the work to be performed in that split.

The former of these two methods has been in common use for many years; the latter was suggested (Mine Ventilation, Beard, 1894, p. 93) as an improvement and has been put in use since in many mines.

The Box Regulator—This form of regulator is shown in Fig. 1, and consists of a brattice built in the return airway or haulway. As shown in the figure, an opening is provided in the brattice and a sliding shutter is used to regulate the size of the opening so as to control the flow of air in that airway or split. If more air is needed the shutter is pushed back so as to enlarge the opening; or the shutter can be partially closed to decrease the quantity of air passing in the split.

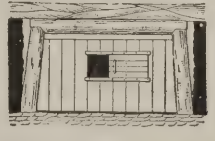


FIG. 1. THE BOX REGULATOR

The Door Regulator—Wherever the conditions will permit this form of regulator to be employed it will be found an improvement over the common "box regulator," just described.

As shown in Fig. 2, the door regulator consists of a door hung at the month of an entry or split and swung into the wind. The door should be arranged so that it will fall naturally against a set-stop, and when not in use will assume a position whereby the air current will be divided in the desired proportion, between the two airways or splits.

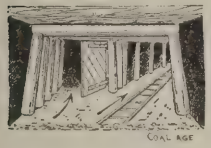

FIG. 2. THE DOOR REGULATOR

The Coal Age Pocket Book

Effect of Regulator—Any regulation of the air current in a mine, to accomplish a distribution of air other than what is natural, causes an increase of both the power producing the circulation and the resulting pressure or water gage. This is true in every case, whatever form of regulator is employed, provided the total quantity of air in circulation is not decreased. The reason that an increase of power is necessary in proportionate splitting, is that an increase in the circulation in any split causes a corresponding increase in pressure; and this pressure is the same for all splits starting from the same point in the mine. To circulate the same quantity of air against this higher pressure requires a corresponding increase of power.

Illustration—Let it be required to find the horsepower and the pressure per square foot, in the following distribution of the air current between the given four splits; the natural distribution of air, as previously calculated, being also given for sake of comparison:

		Nat. Div. (*cu.ft. p. m.*)	Reqd. Div. (*cu.ft. p. m.*)
Split A,	8 × 12 ft., 6000 ft. long,	23,710	20,000
Split B,	6 × 20 ft., 12,000 ft. long,	16,450	40,000
Split C,	6 × 12 ft., 8000 ft. long,	18,750	30,000
Split D,	4 × 6 ft., 1000 ft. long.	41,090	10,000
Total circulation,		100,000	100,000

Solution—The first step is to calculate the natural pressure for each split when passing the required quantity of air per minute, by substituting the following values for the area, perimeter and length of each split, in the formula for unit pressure:

Split A,	$a = 96$ *sq.ft.*;	$o = 40$ *ft.*;	$l = 6{,}000$
Split B,	$a = 120$ *sq.ft.*;	$o = 52$ *ft.*;	$l = 12{,}000$
Split C,	$a = 72$ *sq.ft.*;	$o = 36$ *ft.*;	$l = 8{,}000$
Split D,	$a = 24$ *sq.ft.*;	$o = 20$ *ft.*;	$l = 1{,}000$

The natural pressure for each split is then,

Split A, $$p = \frac{0.00000002 \times 6000 \times 40 \times 20{,}000^2}{96 \times 96 \times 96} = 2.17 \text{ lb. per sq.ft.}$$

Split B, $$p = \frac{0.00000002 \times 12{,}000 \times 52 \times 40{,}000^2}{120 \times 120 \times 120} = 11.55 \text{ lb. per sq.ft.}$$

Split C, $$p = \frac{0.00000002 \times 8000 \times 36 \times 20{,}000^2}{72 \times 72 \times 72} = 13.89 \text{ lb. per sq.ft.}$$

Split D, $$p = \frac{0.00000002 \times 1000 \times 20 \times 10{,}000^2}{24 \times 24 \times 24} = 2.98 \text{ lb. per sq.ft.}$$

The highest natural pressure is developed in Split C, by the required distribution of air, and this is, therefore, the "open" or "free" split, regulators being necessary in each of the other splits, to raise the pressure to that amount.

The horsepower producing this circulation is then,

$$H = \frac{100{,}000 \times 13.89}{33{,}000} = 42.09 \text{ hp.}$$

Inquiries of General Interest

Study Questions--Ventilation

A question that has given us considerable trouble and aroused much interest and discussion is the following:

What must be the area of an airway that will pass 10,000 cu.ft. of air per minute, under a water gage of 1.7 in., the length of the airway being 5000 ft.?

X.

Pittsburgh, Penn.

The only way this question can be worked is to assume that the airway is circular, or square, or has a known ratio of height to the width of airway. The formula for water gage, in terms of the quantity of air in circulation in an airway, is

$$w.g. = \frac{klo q^2}{5.2\, a^3}$$

But the perimeter o and the area a of a circular airway may be written in terms of the diameter of the circle; thus,

$$\frac{o}{a^3} = \frac{\pi d}{(\pi/4, d^2)^3} = \frac{64}{\pi^2 d^5} = \frac{6.484}{d^5}$$

Substituting this value in the previous formula for water gage, and solving with respect to the diameter d,

$$d = 0.03 \sqrt[5]{\frac{lq^2}{w.g.}} = 0.03 \sqrt[5]{\frac{5000 \times 10{,}000^2}{1.7}} = 5.9\ ft.$$

The sectional area corresponding to this diameter is

$$a = 0.7854 \times 5.9^2 = 27.34\ sq.ft.$$

In a similar manner, for a square airway,

$$\frac{o}{a^3} = \frac{4d}{(d^2)^3} = \frac{4\,d}{d^6} = \frac{4}{d^5}$$

Then substituting this value in the formula for water gage, and solving again with respect to d,

$$d = 0.0274 \sqrt{\frac{5000 \times 10{,}000^2}{1.7}} = 5.4\ ft.,\ nearly$$

This being the length of one side of a square airway, the area is

$$a = d^2 = 5.4^2 = 29.16\ sq.ft.$$

For a rectangular airway, in which the ratio of the height to the width of the airway is r,

$$\frac{o}{a^3} = \frac{2\,d\,(1 + r)}{(r d^2)^3} = \frac{2\,(1 + r)}{r^3 d^5}$$

Then substituting this value in the formula for water gage and solving with respect to d, gives, for the width of the airway,

$$d = 0.0238 \sqrt[5]{\frac{lq^2}{w.g.} \frac{1 + r}{r^3}}$$

For example, assuming that the ratio of the height of the entry to its width is 0.6, the width of entry required to pass 10,000 cu.ft. of air against a 1.7-in. water gage is

$$d = 0.0238 \sqrt[5]{\frac{5000 \times 10{,}000^2}{1.7} \left(\frac{1 + 0.6}{0.6^3}\right)} = 7.0\ ft.$$

The height of this airway is, then, $0.6 \times 7 = 4.2$ ft. The area of the airway is

$$a = r d^2 = 0.6 \times 7^2 = 29.4\ sq.ft.$$

::

Cubic Capacity of Anthracite Sizes

Kindly advise me, through the columns of COAL AGE, how many cubic feet per ton there are in the following sizes of anthracite: Egg, stove, chestnut and pea.

H. G. M.

Seneca Falls, N. Y.

The cubic capacity of coal varies with its specific gravity; and, for all accurate determinations in this regard, it is important to ascertain the average specific gravity of the coal in question. For purposes of estimate, however, it may be stated that the specific gravity of anthracite may vary from 1.3 to 1.75, depending on the quality and hardness of the coal and the impurities contained therein. The specific gravity of bituminous coal varies from 1.25 to 1.40, depending on the same characteristics. The average specific gravity of anthracite may be taken as 1.45; and of bituminous coal, 1.3.

Except in special cases, where great accuracy is required, the cubic capacity of the sizes known as egg, stove and chestnut varies so slightly that the difference can be safely ignored, it seldom amounting to over 1 per cent. The difference in cubic capacity per unit weight of sized coal varies mostly with the treatment. In some cases, the sizes, stove and chestnut weigh heavier per cubic foot than the larger egg coal; but, in general, the larger sizes of coal weigh slightly in excess of the smaller sizes, per unit volume. In almost every case, pea coal weighs less per unit volume than the larger sizes. This is due, in part, to the fact that coal is more friable than its impurities and crushes to a finer state. For this reason, the larger sizes naturally contain a greater percentage of impurities than the smaller sizes. However, the market specifications for anthracite are such as to demand special treatment to eliminate these impurities, with the result that the larger sizes of anthracite screenings thus treated, generally, contain less impurities and weigh lighter than the smaller sizes of pea, buckwheat, etc., which are not subject to the same rigid specifications.

As far as cubic capacity is concerned, however, as previously stated, the differences due to size, of screenings may be ignored, as this seldom exeeds 1 or 2 per cent. The general practice in the anthracite region of Pennsylvania, in the sale of coal, is based on the long ton (2240 lb.); while the sale of bituminous coal is always based on the short ton (2000 lb.). A common rule, in practice, based on this fact, is the following:

RULE—*A long ton of anthracite or a short ton of bituminous coal broken to market sizes occupies 40 cu.ft. of space.*

This rule will be found to give practical results.

Examination Questions

Miscellaneous Questions

(Answered by Request)

Ques.—An air current of 140,000 cu.ft. per min. divides at the shaft bottom into three splits, as follows:

Split *A*, 6x9 ft., 9000 ft. long;
Split *B*, 6x9 ft., 12,000 ft. long;
Split *C*, 6x8 ft., 6000 ft. long.

Find the natural division of this current of air.

Ans.—Since the unit pressure is the same for all splits starting at the same point in the mine, the first step is to calculate the pressure potential for each split, by substituting the lowest relative values for the several areas, perimeters and lengths of the airways, in the formula

$$X_p = a\sqrt{\frac{a}{l\,o}}$$

The areas (a), perimeters (o) and lengths (l) of the several splits are as follows:

Split *A*, $a = 54$ sq.ft.; $o = 30$ ft.; $l = 9000$ ft.
Split *B*, $a = 54$ sq.ft.; $o = 30$ ft.; $l = 12{,}000$ ft.
Split *C*, $a = 48$ sq.ft.; $o = 28$ ft.; $l = 6500$ ft.

Reducing these to the lowest relative values, by canceling the common factors in the areas, perimeters and lengths, gives the following:

Split *A*, $a = 9$; $o = 15$; $l = 18$
Split *B*, $a = 9$; $o = 15$; $l = 24$
Split *C*, $a = 8$; $o = 14$; $l = 13$

The relative split potentials are then found as follows:

$$X_a = 9\sqrt{\frac{9}{18\times 15}} = 9\sqrt{\frac{1}{30}} = 9\sqrt{0.0333} = 1.6432$$

$$X_b = 9\sqrt{\frac{9}{24\times 15}} = 9\sqrt{\frac{1}{40}} = 9\sqrt{0.0250} = 1.4230$$

$$X_c = 8\sqrt{\frac{8}{13\times 14}} = 16\sqrt{\frac{1}{91}} = 16\sqrt{0.0110} = 1.6773$$

Sum of relative potentials 4.7435

In splitting, the ratio of the quantity of air passing in each split to the total quantity of air in circulation is equal to the ratio of the corresponding split potential to the sum of all the potentials. This rule gives for the quantity of air passing in each split as follows:

$$q_a = \frac{1.6432}{4.7435}\times 140{,}000 = 48{,}500\ cu.ft.\ per\ min.$$

$$q_b = \frac{1.4230}{4.7435}\times 140{,}000 = 42{,}000\ cu.ft.\ per\ min.$$

$$q_c = \frac{1.6773}{4.7435}\times 140{,}000 = 49{,}500\ cu.ft.\ per\ min.$$

Total . . . . . 140,000 cu.ft. per min.

Ques.—What dangers may arise from the use of electricity in mines? Give your recommendations for avoiding these dangers.

Ans.—Briefly stated, the dangers arising from the use of electricity in mines are as follows: 1. The liability of contact of men or animals with live wires, with the possibility of fatal results. 2. The liability of ignition of gas or other combustible material by sparking of the contacts or the short-circuiting of the current.

When proper care is taken in the installation and due precautions are observed and strict regulations enforced, these dangers are minimized. All medium-voltage or high-voltage conductors should be properly insulated and should not be installed on haulage roads and manways. All conductors and trolley wires should be properly safeguarded at partings or crossings where men or animals are liable to contact therewith. All installations of electric wires and other apparatus should be made by a competent electrician. Fuses, switchboards and other dangerous parts should be protected, and inspected regularly.

Ques.—A pressure of 1.5 in. of water gage gives, in an open airway, 24,000 cu.ft. of air per min. It is desired to reduce this quantity of air in circulation, to 6000 cu.ft. per min., by introducing a regulator in the airway. (a) What will be the required pressure, after the regulator is in place? (b) Assuming the velocity in the open airway was 600 ft. per min., find the velocity of the air current after the regulator is introduced.

Ans.—(a) The question does not state whether the power or the pressure remains constant. Assuming a constant power on the air, the unit pressure (p) will vary inversely as the quantity of air in circulation. In other words, the pressure ratio is equal to the inverse quantity ratio. The unit pressure coresponding to a 1.5-in. water gage is $1.5 \times 5.2 = 7.8$ lb. per sq.ft.; and, calling the required pressure x,

$$\frac{p_2}{p_1} = \frac{q_1}{q_2};\quad \text{and}\ \frac{x}{7.8} = \frac{24{,}000}{6000} = 4$$

$$x = 7.8 \times 4 = 31.2\ lb.\ per\ sq.ft.$$

(b) For the same sectional area of airway, the velocity of the air current will vary as the quantity of air in circulation. The quantity of air being reduced one-fourth, the velocity is reduced in the same ratio, and is, therefore, $600 \div 4 = 150$ ft. per min.

The above solution assumes that the *power* on the air remains constant and the quantity is reduced to one-fourth the original quantity, by means of a regulator. In such case, when the regulator is put in place, the power on the air remaining unchanged, the pressure will be increased four times, giving a $4 \times 1.5 = 6$-in. w.g.

On the other hand, if the question means to ask for the pressure due to the regulator, for a constant *pressure* on the air, it is necessary to calculate, first, the natural pressure due to friction when the quantity is reduced one-fourth. In such case, the pressure varies directly as the square of the quantity; or the pressure ratio is equal to the square of the quantity ratio. The quantity ratio being $\frac{1}{4}$, the pressure ratio will be $(\frac{1}{4})^2 = \frac{1}{16}$. The natural pressure due to friction is, therefore, $1.5 \times \frac{1}{16} = 0.09+$ in. Subtracting this natural pressure from the original pressure gives, for the pressure due to the regulator, $1.5 - 0.09 = 1.41$ in.

Coal and Coke News

Washington D. C.

The Federal Industrial Commission is devoting considerable attention to the question of whether the present situation in coal mining is satisfactory or not and the methods that should be employed if the government determines to interfere in any way between operators and employees. Several hearings have been had during the past week with respect to this question, among the witnesses being John Mitchell, who has revived the suggestion frequently made during the past year or two that there be a commission or counsel of some kind established by the government for the purpose of fixing prices and regulating wages or overseeing both.

This step Mr. Mitchell thought was desirable also from the conservation standpoint, because at present much coal was wasted in the United States, owing to the inability of operators to dispose of it at a profit. The amount which thus went to waste he thought might run as high as 40 per cent. of the total output.

The necessity or at all events desirability of miners' wages being overseen by the government was indicated, Mr. Mitchell thought, by the improved conditions since 1897, there having been much arbitration and conciliation in the industry since that time.

Mr. Mitchell thought the miner was entitled to as good pay as any industrial worker in the country and urged that he should be definitely recognized through some kind of government conciliation process. The commission has evidently been disposed to give careful attention to this phase of the argument and other witnesses have been summoned who will testify along the same general lines. It is understood that the reports of the commission will contain a good deal of discussion of the general question of arbitration and conciliation and that recommendations will be made on that topic.

The attempt is now being made to secure in the pending anti-trust legislation which the administration plans to support some provision that will call for special attention on the part of the trade commission which is expected to be named, to questions of mining and to mine operators' agreements of various kinds. If this could be done, it is thought, there might be less demand for the creation of a special industrial counsel to look after miners' disputes as recommended by Mr. Mitchell and others.

A Decision Is Early Expected

The Interstate Commerce Commission, it is now practically certain, will at an early date announce a decision in the advance rate cases which have been pending before it for some months past. The prevalent expectation is that this decision will provide for some increases in rates, although probably not for advances on the heavier and bulkier commodities which are believed to be bearing at the present time about all of the burden that is properly to be attributed to them.

Among the items on which no advances are expected are coal, cement and other goods in the same general classification. As is well known, Louis D. Brandeis, who has been acting as counsel for the commission, was counsel for the bituminous operators in the Boileau case some two or three years ago, and at that time became firmly convinced that with coal prices at their present figure the producers could not afford to pay a heavier rate for transportation than they are now expected to stand, particularly in the Middle-western region.

During the hearings before the Interstate Commerce Commission the bituminous men have made strong pleas against being subjected to any advance in rates on the ground that they could not keep in business if they were to have to pay more for shipping their coal to lake ports particularly, and probably not if they were required to pay heavier freight rates on coal going to other points.

This decision, while pleasing to coal men, will be much less satisfactory to others, because of the fact that it will necessarily involve the placing of such advances as may be granted entirely upon the other commodities so that the more relief there is for shippers of coal and other bulky commodities the more severe will be the rate advances that must be allowed if there is to be any real concession to the roads on the freight that is less bulky and bears a higher classification.

It is, however, believed that the action of the commission may involve some important announcement concerning the question of cars and practices on the part of shippers who are now receiving special services from the roads free or nearly so.

HARRISBURG, PENN.

The coal situation in the central Pennsylvania, or Clearfield district, where work was suspended on Apr. 11, by order of the operators who control about 85 per cent. of the tonnage output, has been resolved into speculation as to what will be the outcome of the vote to be taken by the miners of the district, and which will be determined by about Apr. 22. By this action the operators have put the matter of settlement squarely up to the men.

The greatest concern has been felt over a possible shortage of coal, but there seems little possibility of such a contingency until the expiration of about six weeks to two months. The operators, foreseeing the present status of affairs, have been shipping heavily from the mines for some time, and they state that there is abundant coal in hand to meet all demands for the time named. In the meantime, hope is expressed on all sides that the differences between the operators and men will be settled before it becomes necessary to call on other fields for shipments, which will be necessary should the deadlock continue longer than about two months.

Hope is the present chief asset of both operators and miners. Representatives of the latter will not venture predictions as to what will be the referendum decision of the miners in their vote. But are of the opinion that the operators are taking this method to bridge over the present slump in the market, as the miners themselves would not have voted to stop work. The operators content themselves with saying that they hope all matters of dissension will be settled amicably long before there is necessity to call outside aid in relieving an imminent shortage.

Reports from the Central district, which comprises Armstrong, Bedford, Blair, Cambria, Centre, Clarion, Clearfield, Elk, Huntington, Indiana and Jefferson Counties, say there is no immediate prospect of coal shortage and that the miners are equipped financially for a long struggle, should that eventuality arise, although there may be suffering in some sections.

The Government Losses a Dissolution Suit

Judges Gray, Buffington and McPherson in an opinion filed on Apr. 7 in the United States District Court dismissed the suit brought by the United States Government against the Delaware, Lackawanna & Western R.R. Co. and the Delaware, Lackawanna & Western Coal Co., for an alleged violation of the commodities clause of the United States statute. This forbids railroad companies engaged in interstate commerce traffic to transport, after May 1, 1908, any article other than timber and its products which may have been manufactured, mined or produced in whole or in part under the authority of such railroad company either directly or indirectly.

The case was considered of the highest importance by the government, as it was one of the steps planned in an effort to break up what it alleged to be a monopoly of the anthracite-coal trade.

The government's contention in the suit was that the Delaware, Lackawanna & Western R.R. Co. and the Delaware, Lackawanna & Western Coal Co. were practically one and the same corporation, and that they were violating the law referred to for the reason that the railroad company was admittedly engaged in transporting a large quantity of coal shipped by the coal company.

It was admitted at the hearing of the case in Philadelphia that the stock of the coal company was largely, if not entirely, owned by stockholders of the railroad company, but it was contended on the part of the defendants that there was a bona fide distinction between the two concerns.

It was contended on the part of the government that the maintaining of the two companies with the stock of the coal company, owned by the stockholders of the railroad company, was a mere subterfuge to evade liability under the statute.

The opinion filed by the judges goes extensively into former decisions in the United States courts, including the Supreme Court, in which the defendant companies, with other firms were involved. It is pointed out that after these decisions, which were adverse to the defendants, the Delaware, Lackawanna & Western R.R. Co., which at the time owned the stock of the Delaware, Lackawanna & Western Coal Co., placed the stock of the coal company on the market, giving preference in the sale to the stockholders of the railroad company.

The court holds that the method of the railroad company in divesting itself of the stock of the Delaware, Lackawanna & Western Coal Co. to have been a substantial compliance with the decision in the former cases.

The decision goes on to say: "No act of Congress, or judicial decision, has declared it to be illegal for any individual citizen to invest his money in two enterprises merely because the two enterprises may be closely connected."

The decision also says further that the facts before the court are to the effect that the two companies are entirely distinct and that the railroad company, which owns the mines and sells coal to the coal company, has no interest in that coal after it is mined, except the interest that it has in the business of transportating the same when it is supplied to it for transportation.

Dealing with another phase of the case, alleged violation of the anti-trust act, the opinion says there was a formal charge against both defendants under said anti-trust act, but that the oral argument left the court under the impression that these charges were not much insisted on by the government. The court's understanding was that what was desired was decision on the alleged violation of the commodities clause, upon which the dismissal was based.

The opinion concludes by saying that a decree may be entered dismissing the bill, but that the dismissal will be without prejudice to the government's right to begin a second proceeding, if the situation changes in the future, and affords the government grounds to assert that the affairs of the two corporations have become unlawfully identified.

A somewhat similar suit was recently instituted against the Lehigh Valley R.R. and its subsidiaries in the Federal Court at New York, and another government action against the Reading to separate it from the Jersey Central R.R. and other interests is in the United States Court in Philadelphia.

PENNSYLVANIA

Anthracite

Wilkes-Barre—When Charles Pamotis rode to his work upon a dangerous plane, thereby violating a rule of the Lehigh & Wilkes-Barre Coal Co., and was discharged, 1200 men and boys at the Maxwell No. 20 colliery declared a strike.

Buttonwood—The recent flood has caused idleness at the Parrish colliery since Mar. 28. The water from the Susquehanna River filled the boiler room outside, necessitating drawing the fires and consequently stopping the pumps inside, allowing such a quantity of water to accumulate that the mine has just recently been cleared sufficiently to allow a resumption of operations.

Bituminous

Uniontown—The nine coke plants and all the coal holdings of the Sunshine Coal & Coke Co. will be sold within the next few weeks. The first plant to be sold is the Cyrilla plant at Lynn Station, consisting of 140 coke ovens and 140 acres of undeveloped coal land. The date for this sale is set for May 1, and the sale of the various other plants will follow.

Washington—Fire of incendiary origin recently destroyed the fan house of the Cherry Valley mine of the Pittsburgh & Eastern Coal Co., located near Burgettstown.

Summerville—It was recently announced that Mines Nos. 5 and 6 of the Pennsylvania Coal Co. would reduce operations to three days per week until further notice. It is expected that this arrangement will cause a number of men to seek employment in other fields, as they will be unable to stand the cut in working hours. A new tipple and other improvements are to be made at No. 6 mine.

Philadelphia — Bituminous coal operators representing about 85 per cent. of the output of central Pennsylvania on Apr. 10 decided to close their mines pending the signing of a new wage agreement. Efforts to arrange a new wage scale to take the place of the one that expired Mar. 31 have been under way for several weeks.

Bernice—Activity in the recently organized mine workers' union at this place has resulted, it is said, in the discharge of a number of men. The matter threatens to create trouble in the district.

Somerset—The Berwind-White Coal Co., which conducts some of the most extensive mining operations in Somerset County, intends to comply with the demands of the miners that motors or other means be supplied so that it will not be necessary for the men to push coal cars about in the mines. To this end the company has ordered 25 motors which will be distributed throughout the several mines to be used for the purpose asked for by the miners.

Greensburg—The Jamison Coal & Coke Co., recently purchased the old Hackley homestead, containing 53 acres of coal and surface. This property is in Salem Township and adjoins the Crabtree mines.

Johnstown—First-Aid Instructor Gomer Phillips, of the Cambria Steel Co., has started the training of 10 men in mine-secure and resuscitation work. Mine-rescue stations with modern equipment have been placed in the Rolling Mill mine and in the Franklin mines of the mining department. Twenty-five miners will take the training in the use of the oxygen helmet and the pulmotor. In addition, men in the blast-furnace and other departments will be given similar instructions.

South Fork—Considerable excitment was caused on Apr. 9, when a section of Lake St., one of the most important thoroughfares of the town, dropped 9 ft. The slip, it is said, was caused by the subsidence of the surface over the workings of the Rockville Coal Co.'s mines. Other causes than that of subsidence were assigned by those connected with the coal company.

WEST VIRGINIA

Wheeling—Coal operators in West Virginia are working their mines to the fullest capacity in order to fill the general demand for fuel coming in from all sections of the country as the result of the suspension of coal production in other states. Manufacturers who were dependent on Ohio and Pennsylvania mines to supply their fuel have been forced to look to West Virginia to fill the deficiency. The principal obstacle the West Virginia operators have to overcome at the present time is an inability to secure sufficient cars to carry away their full production.

Gary—It is announced that a Fourth of July celebration will be held at Gary, which will far excell any holiday jubilee to ever take place in the Pocahontas coal field. The program is already being discussed and plans are on foot for an occasion which promises to eclipse any other independence day celebration in the coal field. It is expected that special trains will be operated to take care of the crowds. Baseball, tennis and other outdoor games will be provided, and fireworks in the evening will form a special feature of the celebration.

KENTUCKY

Madisonville—The strike of the miners at the Kington mine continues, and the mine has now been idle for some time. W. W. Kington, manager and principal stockholder of the mine, conferred recently with city officials regarding the strike, but has announced nothing concerning the course which will be pursued. About 350 miners attended a meeting at Morton's Gap, near here recently, at which the management of the Kington Coal Co. was criticised.

Middlesboro—T. S. Webster & Co. have closed a contract to supply the Southern Mining Co. with the complete equipment needed for the new mine, incline and tipple of the Golden Ash Coal Co., at Neubert, in Harlan County, including screens, dumps, cars, drum, cables, etc., all from the Webster Mfg. Co., Tiffin, Ohio.

Greenville—Reports of lawlessness by a band of night-riders who have been dubbed "Possum Hunters" are persistent, and it is said that various acts of intimidation, all directed against nonunion miners and operators, have been committed. It is declared by nonunion operators that the object of the night-riders is to coerce them into unionizing. Union miners, however, declare that the reports of the trouble have been greatly exaggerated, and that no union man has been guilty of intimidating acts. That the trouble-makers believe themselves to be acting for the interests of the union miners is fairly apparent, although the miners themselves have declared against violence of any sort.

OHIO

Shawnee—The announcement is made that the Peabody mine, at Shawnee, which is owned by Chicago interests, has been permanently closed and the tipple and power house are being dismantled.

Columbus—According to the statement of the Ohio Board of Awards, there is no likelihood of a decrease in the rates on

premiums charged operators for their employees under the employees compensation law. It is claimed the present rates are at the lowest possible figure when the danger of the occupation is taken into consideration.

Ohio coal-mine operators in conference on Apr. 10 decided to test the constitutionality of the Green antiscreen law by filing injunction proceedings in the Federal Court to restrain state officials from enforcing the law which, the operators declare, is the cause of the suspension of work in the Ohio mines. It is expected that the suit will be filed as soon as the committee appointed and attorneys in charge can arrange it.

Steubenville—The Dexter Coal Co.'s mine at Brilliant employing about 150 men resumed operations Apr. 6 after being shut down since Mar. 31. This was the first commercial mine in the state to resume since the state-wide shutdown. The men are, however, working under the old scale, pending the referendum vote.

INDIANA

Brazil—The block-coal miners at a meeting here prepared their demands on the operators, including the weighing of coal before dumping, an advance of 5c. a ton, mine-run basis, an advance of 10 per cent. for all dead work, yardage and day work and changes in the scale of wages for machine mining and for the mining of clay.

Terre Haute—Six of the 16 demands presented by the scale committee of the miners were rejected by the Indiana operators in joint conference here. Action was deferred on the demand that operators deliver powder from magazine to working place. The demands rejected were for a differential of 7c. between pick and machine-mined coal; union-made powder at a fixed price of $1.25 a keg; companies to pay for break-throughs, exemption of machine men from payment of blacksmithing, uniform scale for slate and dirt and payment of wages weekly. The operators opposed all demands that would increase the cost of production.

ILLINOIS

Harrisburg—The first annual first-aid contest of the Saline County Mine Safety Association will be held at Harrisburg, Ill., May 2, 1914. This meet will be of large proportions, and it is anticipated that many spectators will be present. Both single and team contests will be participated in, and the prizes will consist of medals and a silver loving cup. Hotel accommodations should be secured in advance.

Springfield—The State Mining Board of Illinois will hold a meeting at the State House, Springfield, commencing Monday, Apr. 20, for the purpose of examining candidates applying for certificates as mine managers (first or second class), mine examiners and hoisting engineers. Registration of candidates for these examinations will close at 5 p.m., Monday, Apr. 20, at the office of the Mining Board.

ARKANSAS

Fort Smith—A crowd made up of about 1000 union miners and sympathizers on Apr. 6 took possession of the Bache-Denman Co.'s mine near Midland, beat the pitboss into insensibility, roughly handled two guards and a fireman at the mine, pulled the fire from the boilers, chased away the workmen, and after raising an American flag and a banner inscribed "A Union Man's Country" from the tipple marched away led by a band. The mine had upon that day begun operating on an open-shop policy, heretofore having employed about 200 union men. It is announced that the company intends to institute the open-shop policy at its six other mines in western Arkansas and eastern Oklahoma during the coming summer and fall.

OKLAHOMA

McAlester—The state has begun taking legal steps for the purpose of mining coal with convict labor upon the penitentiary farm, the attorney-general having filed condemnation suit covering forty acres against the Choctaw and Chickasaw nations. Coal thus mined will not be sold on the open market, but will be furnished to the state for other institutions, and the money thus raised will be used in maintaining penal institutions.

KANSAS

Breezy Hill—The Sheridan Coal Co. has completed a shaft at Breezy Hill, in the Pittsburg district, and has begun operating. The shaft runs 240 ft. below the ground and is one of the deepest in the Pittsburg field.

Lyndon—Operators of Osage County have filed a complaint with the Kansas State Public Utilities Commission at Topeka, alleging discrimination by railroads entering that field in freight rates as compared to the rates from the Pittsburg field to Kansas points. The Osage mine owners stated the rate on coal mined in that section is about 10c. higher to practically all Kansas points, where a corresponding amount of mileage is involved.

COLORADO

Denver—The supreme court on Apr. 8 issued a writ of Habeas Corpus for the release of "Mother Jones" then held a military prisoner at Walsenburg. This action was a result of a petition presented by Horace N. Hawkins attorney for the striking coal miners. This was the third application for a writ.

MONTANA

Bridger—It is announced that the resumption of commercial coal-mining operations under lease and a complete change in the management of the Bridger Coal and Improvement Co's. properties, will take place within a short time. This is hailed as good news by residents of Bridger since the mines have been shut down for about two years.

Red Lodge—Improvements in the way of new buildings to the value of about $50,000 are to be made at the East mine of the Northwestern Improvement Co. during the course of the next two months. These include a machine shop 36x34ft., a blacksmith shop 30x30 ft., an electrical shop 20x30 ft., and a carpenter shop 30x30 ft., all of which will be located on the south side of present carpenter shop which will be used as a car repair shop. It is expected to commence work on the new mine to be opened under the east bench the first part of June.

PERSONALS

B. F. Fluker, who recently discovered promising beds of coal on his 200-acre tract, near Malakoff, Tex., will develop that field. The vein is said to vary from 6 to 12 ft. in thickness and is from 20 to 40 ft. in depth.

James Martin has severed his connections with the State Mining Department of West Virginia to accept the position of general manager of the Paint Creek Colliery Co., and will make Mucklow his headquarters in the future.

C. L. Patterson is the new superintendent at the W. J. Rainey works at Revere, succeeding Robert Hogsett who was transferred to Grace coal plant. Mr. Patterson was formerly superintendent of the H. C. Frick Coke Co., at the Dearth plant.

Grenville Lewis, of Knoxville, Tenn., has resigned the presidency and general managership of the Ideal Block Coal Co., of Lily, Ky. He will be succeeded on or about Apr. 21 by Edward H. Coxe who until recently has been manager of operations for the receiver of the La Follette Coal Iron & Ry. Co. Mr. Coxe will probably reside at Corbin, Ky.

H. H. Pinkney, general superintendent of the Flat Top Coal Mining Co., has tendered his resignation from this position in order to take the general managership of the International Coal Co. of Montana, with headquarters at Bear Creek. Mr. Pinkney has held positions as superintendent and mine inspector in West Virginia for the past 14 years, making many friends and winning the respect of both operators and miners by his straightforwardness and kindly manner. It is the wish of his many friends throughout the state that he be as successful in his present undertakings as he has been in the past.

OBITUARY

James B. Davis, of Plymouth, Penn., died of heart trouble on Apr. 8 after an illness of several months. Born in Brecknonshire, South Wales in 1840, Mr. Davis came to this country when 28 years of age and soon accepted the position of outside foreman at the Nottingham colliery of the Lehigh & Wilkes-Barre Coal Co. Nine years later he accepted the general superintendency of the Plymouth Coal Co., which position he occupied until he retired to private life five years ago.

Mr. Davis was recognized both in this country and abroad as an efficient executive and as a pioneer in the practice of flushing for surface support. Upon this subject he wrote several articles for the technical press of this country and Germany. He is survived by his wife and nine children.

Andrew J. Dull, a well known citizen and pioneer coal

operator of Pennsylvania, died at his home in Harrisburg, Apr. 8, from general breakdown due to old age, he being at the time of his death in his 85th year.

After his graduation from Princeton University in 1852, Mr. Dull was engaged in the construction of public works later becoming interested in the iron industry and the construction of iron mills. He also became indentified with the coke industry of the Pocahontas region of W. Va. During his latter years, however, Mr. Dull gave less attention than formerly to the iron and coal business proper and as president of the Electric Ore Separator Co. gave much of this time and thought to the separation of magnetic and non-magnetic minerals. He is survived by his wife who before marriage was Judith Reynolds, of Kittanning.

CONSTRUCTION NEWS

Mater, Ky.—Work has been begun on an electrically equipped coal plant by the Elkhorn Coal Co. It is expected that from 800 to 1000 tons of coal will be shipped per day, the shipments to begin about July 1.

Greensburg, Penn.—Byrne Bros., who purchased the Mathias farm, near Malison, last year, together with several small additional tracts of coal, have a force of men erecting a tipple for the development of this field.

Viper, Ky.—The Lexington & Eastern R.R. will build five miles of branch line from Viper into the coal and timber fields of Mason Creek to reach coal and lumber developments now under way. It is stated that work will start at once.

Stone, Ky.—The Island Creek Coal Co., operating in West Virginia, has announced its intention of entering the Kentucky field. It will operate and develop several thousand acres along Pond Creek, work upon which will start within a few weeks.

Shelby, Ky.—It is announced that the Shelby Coal Co. recently organized with a capital of $60,000, will start work immediately on a first-class coal-mining plant just up Shelby Creek, on the Sandy Valley & Elkhorn R.R. Active preparations are being made to start the initial work.

Lexington, Ky.—In an effort to rush the construction of the Yount's Fork branch of the Lexington & Eastern Ry., Brady & Mundy, the contractors, have put 200 extra men on the work in the Boone's Fork coal field. The Mineral Fuel Co. is preparing for extensive coal operations in that section.

Pikeville, Ky.—Development work is well under way on the new plant of the Sharon Coal & Coke Co. on Blackberry Creek on the Pond Creek branch of the Norfolk & Western R.R. Several million dollars will be expended in this development and the building of a first-class mining and industrial city will be a feature of the undertaking.

Whitesburg, Ky.—Another railroad line to tap the rich Boone's Fork and Elkhorn coal fields of Letcher County has been announced. This will be known as the Beaver Creek branch of the Chesapeake & Ohio, starting from Steels Creek and passing through the head waters of Beaver and Rockport creeks, penetrating rich coal and timber sections.

Hazard, Ky.—Five hundred acres of coal land have been leased from the Slemp Consolidated Coal Co. by W. N. Heath and J. G. Davis. A first-class electrically operated plant will be installed five miles north of Hazzard on the Lexington & Eastern R.R., and it is expected to soon have a daily capacity of from 700 to 800 tons, and that shipments of coal will be started by June 15.

Elkhorn City, Ky.—The construction work on the 30-mile line of the Carolina, Clinchfield & Ohio R.R. from Dante, Va., through "the Breaks" of the big Sandy River to this city is being rushed with all possible speed. Owing to the trouble with the long tunnel work it is feared that traffic will not be established on this line before Aug. 1, although completion was expected to be made by May 1. This is one of the most expensive pieces of railroad ever undertaken in the South.

NEW INCORPORATIONS

Palmer, W. Va.—The Blacksburg Coal Co. has been incorporated with a capital stock of $200,000 to develop coal land.

Charleston, W. Va.—The Griffith Coal Co. has been incorporated with a capital stock of $1,000,000 to develop coal mines in the Sherman district.

Cullman, Ala.—The South Brilliant Coal Co. has been organized with a capital stock of $10,000 to develop mines in Marion County. The president is Geo. H. Parker, of Cullman, Ala., the other incorporators being A. A. Griffith and O. S. Goodwin.

Uniontown, Penn.—The Ten Mile Coke Co. has been incorporated under the laws of Pennsylvania with a capital stock of $5000. The purpose of this firm is to manufacture, sell and otherwise deal in coke.

Bowling Green, Ky.—The Premier Products Co. has been organized with a capital stock of $300.000. The incorporators are Arthur Cobb, F. C. Mills, B. T. Calaway and F. E. Hanson, all of Cleveland, Ohio.

Sutton, W. Va.—The Strange Creek Coal & Coke Co., of Braxton County, has been organized with a capital of $200,000. The incorporators are E. S. Areford, F. P. Truesdale, J. C. Hibbs and L. S. Masten, of Uniontown, Penn., and Levi Seigel, of Bittner, Penn.

Winnipeg, Manitoba—The Anglo Alberta Coal Co., Ltd., has been incorporated for the purpose of mining with a capital stock of $800,000. The head office will be in Winnipeg, and the incorporators are E. C. Comblin, R. G. Holmes, N. McKay, S. W. A. Seward and P. Morgan.

INDUSTRIAL NEWS

Pittston, Penn.—The office force of the Lehigh Valley Coal Co. at Upper Pittston, will remove from the present location to more commodious quarters at Wilkes-Barre in the near future.

Huntington, W. Va.—The Elk Horn Fuel Co., which owns a large acreage of coal land in eastern Kentucky, has announced that a 2½ per cent. semiannual dividend has been declared on its preferred capital stock, the same made payable May 1.

Freeburn, Ky.—The Turkey Gap Coal Co. announces that on or about Apr. 20, there will be an increase made in its coal shipments, that on and after that date it expects to ship 80 cars or thereabouts per day. An increase has already been made in the working force of the mine.

Washington, Penn.—By a final decree handed down by the court here Apr. 9, the Pittsburgh Coal Co. loses in its contention that fraud existed in the deed given by the late Francis L. Robin, formerly president of that company, transferring 90 acres of valuable coal land underlying the Washington Fair Grounds at Arden.

Scranton, Penn.—It is reported that it is probable that in a short time there will be a combination of three coal companies of Scranton, the Traders Coal Co., the St. Clair Coal Co., and the Robertson Coal Co. will be combined into one large corporation. It is said that W. H. Taylor, of New York, formerly of Scranton, is the leading spirit in the proposed combination.

Baltimore, Md.—A receiver for the Fairmount & Baltimore Coal & Coke Co. was recently applied for by various stockholders. That the company is insolvent is among the allegations in the bill of complaint. This firm was incorporated in West Virginia and operates a mine at Clarksburg in that state, and had an authorized capital stock of $50,000.

Cleveland, Ohio—A Cleveland vessel owner recently took a contract to transport 200,000 tons of soft coal for delivery at a dock at Superior during the coming summer at 30c. Shippers generally will not be in the market for another few weeks and several vessel owners are in no hurry to charter their boats for coal until they know how much ore they will be able to secure.

Washington, D. C.—Attorney General MacReynolds recently stated that the Government would appeal in the Lackawanna case to the United States Supreme Court. He said it was the first time the commodities clause had come up for judicial decision, and that the Government would, of course, take it to the highest court as the railroad would have done had the decision been the opposite.

Whitesburg, Ky.—It is reported that the recent trouble between the coal operators in eastern Kentucky and southwestern Virginia and the Louisville & Nashville R.R., and other railways entering the territory over unreasonable and discriminatory rates on northbound coal has been settled. This matter of rates has been for some time in the hands of the Interstate Commerce Commission.

Coal Trade Reviews

General Review

Anthracite continues strong and active. Bituminous dull with prevailing circulars under heavy pressure. More than enough coal coming in to supply current requirements. No signs of improvement in the immediate future.

The customary spring activity prevails in the anthracite trade. Mines are working up to the full limit and nearly all the companies report more orders for April delivery than they will be able to fill. The movement has been heavy, and the cool weather has caused an unexpected consumption so that the tonnages carried over in the bins of the consumers will be materially reduced.

Even in the face of what appears to be an indefinite suspension, bituminous quotations are under a severe test because of the effort to force coal on an already over-stocked market. The general contraction in all lines continues, and coal is now shipped only on specific orders, the general market being too uncertain to risk demurrage. Stocks at tidewater are heavy, and, in view of the light demand, conservative observers believe there is sufficient production in the nonunion districts to take care of the consumption and that the situation may continue indefinitely on the present basis. With plenty of coal coming in and large stocks on hand, there certainly is no cause for anxiety, and it will be interesting to see how operators maintain prices during the summer. In fact, buyers do not regard the situation seriously, and there is so little business being negotiated that the market is hardly quotable.

Production in the Pittsburgh district is at less than half capacity, with shipments confined entirely to contracts. Some relief is anticipated when the lake season opens, but at the present time consumers are using up surplus stocks, a great deal of which is on demurrage. It is estimated that it will take about a month to clean up the storage supplies. With practically all the mines in Ohio shut down, the market continues at a complete standstill, and the entire interest of the trade is concentrated upon the proceedings initiated to test the validity of the recent adverse legislation. Steps are also being taken toward holding another conference over the wage scale and, on the whole, the situation in Ohio has taken a decided turn for the better. Quotations at the Hampton Roads piers have been well maintained, in fact, much better than at the distributing centers; dumpings have also been heavy, and indications are that they will continue so through the balance of the month, while there is only a normal accumulation in the railway yards and a fair amount of tonnage due. The rather grave situation in the union fields has not affected the West Virginia trade in the least.

Plenty of coal is still available in the Middle-west, while operations are practically at a complete standstill and the market appears to be getting steadily weaker, with prices showing a tendency toward lower levels. The adverse conditions on prompt business are making it difficult for operators to negotiate on the new contracts as is also the uncertainty in the labor situation.

EASTERN MARKET

BOSTON

Little change in Pocahontas and New River. "Market cargoes" still a danger spot on season prices. About 65@70% of the steam contracts are reported closed. Pennsylvania grades quiet and Georges Creek dull. Anthracite coming forward freely.

Bituminous—The market for Pocahontas and New River shows no appreciable change from a week ago. "Dull" is the word everywhere and no improvement is expected for weeks to come. The base price is being fairly well maintained on spot business f.o.b. Hampton Roads but as much cannot be said for quotations at the distributing points. Cargoes continue to arrive at this end without disposition orders and prices have suffered through the effort to force supplies on a reluctant and already over-stocked trade. This has its serious aspect when considered in connection with contract business on which all the shippers are most anxious to see the regular basis maintained. About 65@70% of all season business on Hampton Roads coals in this section is now understood to have been placed and it would be a great pity if the various agencies should have to make ruinously low prices through foolish moves on the relatively small and scattering tonnage that is yet to be closed.

There are few "bull points" in the situation here. With the large volume of Southern coal available for this territory it is very doubtful if the $2.85 price carries through. There are some who freely predict lower prices in June and July. In some instances the price has been shaded but as a rule the operators themselves are holding the strings and are firm in their purpose not to mine coal at a loss.

The trade in the Pennsylvania coals is also very quiet. An increasing number of the larger all-rail contracts are placed each year in May and June rather than in April, so that with labor conditions more or less upset, in addition to other uncertainties, there is little doing on season orders. At tidewater there is no change. Coal is being sent to the loading piers only on special orders, the general market being too unreliable for shippers to take risks of demurrage or of softening prices.

Anthracite—Receipts continue heavy at all the ports and retail trade is remarkably brisk for the season. The cool weather has kept up with hardly a break, a condition that argues well for the demand in the summer and fall. The amount of hard coal carried over by consumers this year will be the smallest for several years.

Bituminous prices are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@1.50	$1.25@1.65	$1.67@1.77	
Philadelphia*	2.20@2.75	2.50@2.90	2.92@3.02	
New York*	2.50@3.05	2.80@3.20	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.80@2.85
Boston†				3.63@3.78
Providence†				3.60@3.78

*F.o.b. †On cars.

NEW YORK

Anthracite mines working full time with more April orders than can be filled. Some uncertainty regarding the retail circular. Bituminous continues heavy and with no indications of any improvement in sight.

Anthracite—While the hard-coal companies are all working up to full capacity there is a tendency to hold off in the local market, dealers hesitating to buy because of the increase in prices and some uncertainty as to what the summer discounts will be. It is understood just now, that in view of the increase of 25c. in the retail circular, the New York dealers probably will not make the customary advance of 10c. per ton on May 1. On the other hand it is stated that the Brooklyn dealers will make this advance as usual, in which event there will be a differential of 10c. per ton between the New York and Brooklyn price on prepared coal when the full winter schedule finally goes into effect.

While mines are all working full time, it is noted that off prices are occasionally obtainable on tonnages of individual coal threatened with demurrage, particularly at the lower ports. The large companies report more orders for April than they will be able to fill, and indications for the next month are generally bright although a little doubtful in tidewater business.

The good grades of pea coal are in fair demand at the upper ports where there is some scarcity due to considerable of this grade being diverted into the line business; shipments to the lower ports are not so available for the rail trade and pea coal is in plentiful supply there. About the same condition prevails on No. 1 buckwheat. The poorer grades of No. 3 buckwheat are exceptionally long, while the off qualities of No. 2 are also heavy, but somewhat stronger than either Nos. 1 or 3.

The New York market is now quotable as follows:

	Upper Ports		Lower Ports	
	Circular	†Individual	Circular	Individual
Broken	$4.60	$4.60	$4.55	$4.55
Egg	4.85	4.85	4.80	4.70@4.80
Stove	4.85	4.85	4.80	4.70@4.80
Chestnut	5.10	5.10	5.05	4.95@5.05
Pea	3.55	3.55	3.50	3.35@3.50
Buckwheat	2.80	2.80@2.90	2.50@2.75	2.35@2.75
Rice	2.30	2.30@2.40	2.00@2.30	1.80@2.25
Barley	1.80	1.80@1.85	1.70	1.40@1.75

Bituminous—Even with a suspension now nominally in effect the general contraction in the soft coal market continues. There is not a ripple of any kind in the trade, buyers refusing absolutely to take the situation seriously. There is a lot of coal coming in from the nonunion fields in West Virginia and stocks at tidewater are generally considered heavy particularly at Port Reading. Whether this was brought down on speculation or as a protection against a possible shortage, it appears doubtful if it will be required.

Even the optimists generally agree that the immediate future of the bituminous trade is shrouded in gloom. With the entire absence of any demand whatever, as a result of the depression in all lines of industrial endeavor, it is felt in all quarters that there is sufficient coal being produced to meet the reduced requirements. Under more normal conditions there would have been some spurt in the coal market by this time, but the situation may continue unchanged indefinitely without more than a slight advance in prices.

Low quotations are occasionally heard on demurrage coal. As a rule, however, there is so little business being negotiated that there is hardly any market at all and we continue nominal quotations on the same basis as for the past several weeks as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

PHILADELPHIA

Anthracite trade still continues satisfactory. Steam sizes likely to improve if bituminous suspension is long continued. Soft coal quiet, with orders down to a minimum, and no indications of any change in the near future.

Anthracite—Work at the mines continues full with the exception of the Easter holidays. This, however, is to be expected at this season of the year, although coming so late, it has thrown the production back just that much. All sizes seem to be in good demand, with the call centered on egg and stove. It is understood that the market has been such that the production of egg is not sufficient to supply the demand, and considerable of this coal is being picked up. Early deliveries of this size, however, are the rule, rather than the exception. The scarcity of stove is making substitutes necessary and egg is invariably the size suggested. The market for chestnut does not appear to improve, the current output is being taken care of, but there is apparently no necessity for calling on reserves. Pea is about the only grade on which concessions are being offered; anywhere from 20 to 35c. from the circular price is being quoted in some cases. Prices at tidewater rule about the same as the week previous, with the possible exception of pea, as follows:

	Circular	Individual
Broken	$4.25	$4.35 @ 4.50
Egg	4.50	4.50
Stove	4.50	4.60
Chestnut	4.75	4.75
Pea	3.25	3.00 @ 3.10

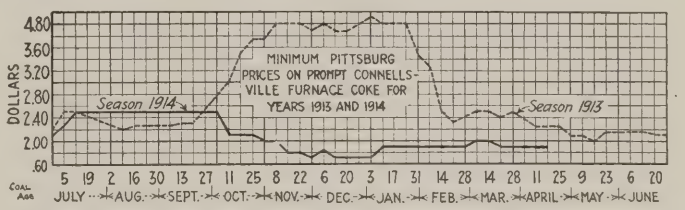
Bituminous—In the face of what looks like an indefinite suspension at the mines, the bituminous trade shows no apparent change. As a matter of fact, conditions are even worse than reported last week. Predictions of the possibility of short supplies, meet with little interest, and there seems to be no difficulty in obtaining plenty of coal at the prevailing prices of the last two months, or even less.

BALTIMORE

Dull and uninteresting conditions mark the bituminous trade. Some uncertainty due to Central Pennsylvania suspension. Slump in slack. Anthracite trade in dull list too.

The bituminous trade is generally dull. Not only is there a decided let up in the call for prompt coal, but a noticeable slowing down in contract inquiries as well. There is little new business developing while it is difficult to keep the old trade up to normal. One element of uncertainty is the suspension in Central Pennsylvania. While this coal as a usual thing only touches the situation here to a limited degree, a suspension will create an increased demand.

A discouraging feature of the situation in West Virginia the past week was the growing weakness in slack. Sales at the mines around 70c. were recorded in some instances. Three-quarter gas, largely by reason of poor prospects in the Lake trade, was not over strong either. Sales were noted around 85 and 90 cents. No change was noted in the price list for Pennsylvania coals. Little, even of poorer grades, was to be had below $1.05 while the best grades still command from $1.30 to $1.40.



The anthracite trade here continues listless. While there has been talk of adding to the schedule to cover the Pennsylvania mine tax, some dealers have been offering coal about on the same basis as last spring.

CENTRAL STATES

PITTSBURGH, PENN.

Pittsburgh district producing less than 50% of capacity, with many mines entirely idle. Lake shipments promise to be very light up to July 1, with fairly good movement later. Coke market very dull.

Bituminous—Production in the Pittsburgh district is at considerably less than 50% of capacity, and many mines are entirely idle. This, in despite the fact the whole state of Ohio is idle and central Pennsylvania is doing practically nothing, on account of wage disagreements. Present shipments from the Pittsburgh district, limited as they are, are chiefly against contracts and hardly any coal is being bought so that no definite market is developed. It is claimed that occasional sales are made at the regular list, but it would appear that little difficulty would be experienced in securing coal at cut prices, except possibly in the case of slack, which is far from plentiful, by reason of the light production of screened coal. Consumers are using up their stocks as fast as they can, and taking as little as possible from mines. In many instances the coal stocked is subject to demurrage. The early prospects for lake shipments are poor, and the movement up to July 1 is likely to be small, but shippers are expecting that the season as a whole will not show much decrease from 1913. List prices are: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market is quiet and not overly strong, as consumption is tending to decrease rather than increase. No important transactions are reported for the past week. We repeat former quotations: Prompt furnace, $1.90 @2; contract furnace, $2; prompt foundry, $2.40@2.50, per ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ending Apr. 4 at 356,320 tons, a decrease of 3698 tons, and shipments at 348,950 tons, an increase of 1460 tons. The production exceeded the shipments by 8830 tons.

BUFFALO

Mining suspension extending fast much to the satisfaction of the operators as there is little market for bituminous coal. Prospect of light production for the rest of this month.

Bituminous—There is no improvement in the demand as the consumer is heavily stocked up and will not be in the market for some time. At present the miners are mostly idle all through the bituminous districts of Pennsylvania and it is believed that no great amount of work will be done before May.

Reports from the Allegheny Valley mines state that the local miners' unions have refused to obey the orders of their officers to continue at work and in some instances have dismissed them and elected new officers, in order to obtain authority for suspending. This is, of course, entirely satisfactory to the operators, who are unable to sell coal at a profit. As it looks now business for some time will be confined to filling the existing contracts. It will require at least a month to use up the surplus already in consumers' hands. The future of the trade is uncertain, the most favorable feature at present being that consumption is once more greater than production.

The nominal market is weak and dull, except that there is some natural demand yet for slack, at prices based on $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.25 for slack, with little doing. Allegheny Valley coal is about 25c. lower, except that the better condition of slack brings it about on a par with Pittsburgh.

Coke—The demand is not improved and so long as iron and steel remains so quiet there is little to be expected of the coke market. Dealers report the price of 72-hr. Connellsville foundry at $4.50, which appears to be a bottom quotation.

Anthracite—The activity in the anthracite market is not great, but there is a good volume moving and shippers find it impossible to get much surplus for water shipment. The cold March and April have cleaned up the stocks in a way that was not anticipated. The opening of the lakes promises to be late so the season will probably be active; the failure of iron ore to move is holding everything else back at present.

A report from the north-shore ports of Lake Ontario is favorable to a good season, as the supply laid down there last year is well exhausted. Coal will be loaded at both Oswego and North Fair Haven for lake shipment this week The bituminous movement from Charlotte continues all winter, but there is no activity at Sodus Point yet.

TORONTO, CAN.

Plentiful supplies and business normal. Active Lake trade in anthracite anticipated.

Trade is normal for the season with abundant supplies on hand. Dealers having anticipated the labor troubles made provisions accordingly, and have stocks on hand sufficient to last for about two months.

As soon as navigation has fairly opened large orders will be placed for anthracite for delivery by water. The usual reductions in price will be made next month, but meantime quotations remain unchanged as follows: Retail anthracite egg, stove and nut, $8.25; pea, $6.75. Bituminous steam, $5.25; screenings, $4.35; domestic lump, $6, cannel, $7.50. Wholesale f.o.b. cars, three-quarter lump, $3.75@3.85; screenings, $2.90@3.

COLUMBUS

Meeting of Ohio operators the feature of the industry during the past week. All Ohio mines are still closed and the trade is at a complete standstill. Prices unchanged.

Ohio operators met in Columbus last week and decided to test the Ohio mine-run law as soon as practicable. Action was also taken looking toward a conference between the operators and miners with a view to receiving the latter's proposition on the renewal of the wage scale. It is felt generally that considerable progress has been made toward solving the snarl in the Ohio coal trade.

The suit to test the constitutionality of the mine-run law will be brought by a Cleveland firm of attorneys in the United States court. It will be in the form of an application for an injunction to restrain the state officials from enforcing the new law after May 15 when it becomes effective on the grounds that the law curtails the freedom of contract which is guaranteed by the constitution of the state of Ohio as well as the United States. It will also be urged that the law illegally confiscates property.

There was a slight difference of opinion between the operators in Eastern Ohio and the Hocking Valley with reference to conferences with the miners. The operators from No. 8 district were loath to treat with the men until after the new law was tested. Producers from other fields believed that they could proceed with their conferences with the miners and if possible get a scale with both the mine-run and the screen basis. A conference of operators and miners is scheduled for some time soon.

The coal trade has been quiet in every respect. As no coal is being produced in this state there is practically no market or supply. Dealers stocks appear to be sufficient for all current needs up to the time of the stocking up period and consequently there is little likelihood of a fuel shortage.

Steam trade is also dull. Practically all steam users have stocked up with a supply to last for 60 to 90 days. Their fuel requirements are not very large because of the dullness which prevails in the manufacturing line. Railroads have taken off many trains and as a result their fuel requirements are decreasing right along.

What quotations are being made in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.45 @ 1.35	.....	$1.50 @ 1.40	$1.40 @ 1.35
¾ inch	1.30 @ 1.25	$1.20 @ 1.15	1.35 @ 1.30	1.30 @ 1.25
Nut	1.25 @ 1.20	.....	1.30 @ 1.25	1.25 @ 1.20
Mine-run	1.15 @ 1.10	1.10 @ 1.05	1.15 @ 1.10	1.15 @ 1.10
Nut, pea and slack	0.90 @ 0.85	.....	0.90 @ 0.85	0.80 @ 0.75
Coarse slack	0.80 @ 0.75	1.00 @ 0.95	0.80 @ 0.75	0.70 @ 0.65

CLEVELAND

Spot coal heavy at low prices. Demand for prompt Pocahontas good in the smaller towns, but slow with local dealers. Lake chartering heavy during the week.

Since shipments from the mines have stopped a few grades of coal are beginning to disappear from the spot market although prices are hardly altered. The only advance noted during the week was a slight premium on Pocahontas egg among dealers in the smaller towns about Cleveland. Lump is plentiful.

The retail dealers of Cleveland are accumulating all the hard coal they can. Few yards are in a position to store as much anthracite now as they ought to because they have surplus steam coal in the bins.

During the last week vessel capacity to transport 600,000 tons of bituminous coal from Ohio ports to Superior was chartered at 30c. There are offers of 27½c. for the same service, but those who are making them have not actively sought boats recently. With one or two exceptions the lake coal shippers are not considering chartering for another two weeks or more. The stocks at Duluth-Superior docks were estimated at 2,000,000 tons the first of the month. Docks at the upper lake ports are in about the same shape and will not need coal until well into June or early July.

Navigation opened officially Apr. 15, but owing to the channels at the Straits of Mackinac and Sault Ste. Marie being filled with ice, boats did not leave for upper lake ports. It will be Monday or Tuesday, Apr. 20 or 21, before it will be possible for ships to pass these points.

The local market for slack was a little stronger toward the last of the week and was even more so early this week. Coarse coals are still a drug on the market. There has been some inferior coal, from mines that usually ship other markets, that could not be moved.

Fairmount shippers sold a large amount of slack a month ago at 75c. This has come into the market during the last few weeks and has been sold at a loss of 5 to 10c. The same slack can be bought at 65c., which makes it cost $1.80 here, 5c. over the market. Three-quarter No. 8 is being offered at $1.20 at the mines for shipment and mine-run at $1.10. The freight rate is 90c. Middle district coal for shipment, freight rate 70c., is being offered at $1.30 for three-quarter and $1.20 for mine-run.

Sales agents of Ohio mines are meeting with considerable difficulty closing contracts. The buyers want a definite price which coal operators of Ohio are unable to make. The mining scale and spotting charges are still to be established and will effect the price. The consumers are not willing to buy subject to advances equal to the increased expenses possible through these sources. They point to the settlement of the western Pennsylvania wage question and explain they can buy on a definite price from that field.

The spot prices f.o.b. Cleveland are as follows:

	Pocahontas	No. 8	Middle District	Youghiogheny	Fairmount
Lump	$2.95*				
Lump, 1¼-in.				$2.50*	
Lump, 2½-in.					$1.90@$2.00
Lump, ¾-in.		$1.90	$1.90	2.40*	
Egg	2.95*				
Mine-run	2.60*	1.80	1.80	2.30*	
Nut		1.85		2.20*	
Slack	2.60*	1.75	1.65@ 1.70	1.90	1.75

* Indicates price for shipment.

CINCINNATI

Market weak but steady. Dealers report that most buyers have large tonnages stored. Outcome of West Virginia conference between operators and miners being anxiously awaited.

Uncertainty as to the outcome of the conference of operators and miners in the West Virginia field is occupying the attention of the local trade. Local managers are of the opinion that an amicable arrangement will be arrived at. There is little new in the market in the way of prices and but a fair amount of business is being transacted although dealers confidently look for a sharp demand within the next ten days or two weeks. The quiet attitude is not causing any considerable alarm as this is the season between buying periods. But little new business is being offered, the majority of coal now being moved, representing contract orders. There is some coal on the tracks here awaiting delivery, but much less than two weeks ago.

Dealers in Pocahontas are the only ones that report a good movement and while there is no heavy demand for the same, still the market is steady with prices firm. Pennsylvania mines are operating from three to five days a week and are doing this only to keep their men at work. They state that they have plenty of coal on hand with a rather light demand. New River domestic coal is reported as sold up for the month of April with an active demand for later. Good prices prevail on New River.

DETROIT

Consumers showing some anxiety over the labor situation. Ohio grades slow with West Virginia active. Large tonnages of anthracite moving.

Bituminous—Several large contracts have been closed, three-quarter lump being negotiated at $1.10 per ton, with mine-run at $1, and, occasionally, $1.05. Slack coal is in good demand at 90c. for spot shipments and 85c. on contracts for the new year.

Ohio coals are slow, the trade believing that it is hardly worth while to negotiate for these because of the unsettled conditions there. Pocahontas grades are active and Kentucky coals are arriving in greater abundance than ever before. Manufacturers are beginning to evince some anxiety over the situation and are taking pains to ascertain whether shipments on contracts will be maintained. The outlook is much better on steam coals but is less favorable on the domestic grades, the demand for which is weak.

Anthracite—There is a great deal of activity evident in hard coal, dealers making every effort to get their full quota of all sizes at the minimum April circular. No track coal is to be found, immediate disposition being made upon arrival, some dealers even paying a premium of 10c. per ton in their anxiety to obtain the coal.

Coke—Coke is moderately active, contracts for Connellsville being closed at $3, with Semet Solvay at $3.25 and gas house at $2.90, all f.o.b. ovens.

HAMPTON ROADS

Week's dumpings very good. Large shipments to both West Indian and Italian ports. Prices on all grades firm.

Dumpings over the piers at Hampton Roads for the week have been heavy. The largest cargo went into the U. S. Collier "Orion" this vessel taking 11,329 tons from the piers of the Virginian Ry. in the short space of 7 h. and 55 min. The demand for run-of-mine, both Pocahontas and New River, is still excellent and the indications are that there will be a good movement over tidewater piers all through the month. Although there has been some demand for prepared coal there is practically no call for the high volatile grades.

There has been no change in prices during the week. Export cargoes have gone to Naples, Kingston, Curacao, Leghorn, Canal Zone, Bridgetown, St. Lucia, Port Antonio, Havana and Santiago. The accumulation in the railway yards is about normal with a fair amount of tonnage due.

LOUISVILLE, KY.

Freezing weather has helped the retail market to some extent, but not much business has been handled. A growing scarcity of screenings; prices rising.

Unseasonably cold weather during the past week kept the retailers busy delivering small orders as many domestic consumers found it necessary to have fuel after expectation of any such a need had passed. This naturally did not make up any great total volume of business, and while the operators received a few orders, the market was dull. As yet there is no indication of a stocking movement in any section, despite the rather grave labor situation, and prospects are for a slow domestic market, and a correspondingly tight steam market, for some time to come.

The short production of the prepared grades has at last resulted in a marked scarcity of screenings, and prices have stiffened lately, especially on the Western Kentucky product where curtailed operations have made the shortage quite acute. The railroads are taking practically no mixed coal from this district just now, making pea and slack, hard to get, with nut and slack also scarce, while the market generally is stronger than for some time. Western Kentucky sales at 75c. a ton f.o.b. mines are reported, which is nearly as high as the better Eastern Kentucky grades, although, of course, the lower freight rate cuts a figure in this price. Domestic prices are stationary at the low level which has been maintained for some weeks.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM

Some orders for domestic lump booked at spring prices but market is very quiet. Steam coal continues dull and furnace and foundry coke show little change. Practically nothing doing in pig iron. Car supply adequate.

Even though all operators have put the spring prices into effect, the retail dealers are holding off buying, believing that the regular schedule will not be adhered to, and that they will be able to buy at a reduced price later. However, it is probable that no reduction in these prices will be made, even with a fair business. Some of the retailers have booked orders for spring and summer shipment, but the tonnage has not been as large as usual during the first two weeks of April. The market on steam coal still continues quiet, but the prices are not being reduced, except in a few rare instances on demurrage coal.

The manufacturers of coke state that there is practically no business to amount to anything either on furnace or foundry coke. Blacksmith coal, however, is in a satisfactory condition. All furnaces report small sales of pig iron, with no immediate relief in sight. The car supply is sufficient to take care of the present business.

INDIANAPOLIS

Mines have been gradually closing since Apr. 1, partly for repairs and partly because of the heavy stocks. Will probably resume sometime this month.

While the miners of the state have been willing to continue at work, pending the fixing of a new wage agreement, the mines have gradually been shutting down since the old contract expired Apr. 1. Most of the large consumers in the state have stocked up heavily with coal and can give no more orders to the mines. As there is also considerable coal in cars at the mines, junction points and terminal yards, this has been available for current trade. Owing to the urgent demands of the public utilities and other large consumers, they have had preference and retail yards have had to wait. As a result some of them have run out of Indiana coal, particularly the domestic grades, the demand for which has kept up on account of touches of freezing weather.

Another reason for closing down of the mines was the necessity for repairs caused after steady operations for two months practically at full capacity, on account of a stretch of several weeks of snow and cold. While the mines are closed, operators are busy renewing contracts. This is progressing satisfactorily and practically on the same basis as last year. A clause in the contracts protects the operators from loss in case of an advance in wages. Prices at the mines have not been materially changed. Retail quotations in this city continue on the basis set Sept. 20 last, although summer prices will soon prevail, after the new wage scale is settled.

CHICAGO

Market dull with many uncertainties. Despite the general curtailment, there has not been sufficient business to absorb the surplus tonnages accumulated in anticipation of the suspension. Dealers' stocks are low, but buying is light even at the April discount.

A great deal of uncertainty has developed in the smokeless market as a result of the tendency on the part of jobbers and agencies to speculate on this grade. That, and almost violent fluctuations in the spot market has made it exceedingly difficult for the companies to prevail upon buyers to sign up contracts. The larger agencies are holding determinedly for $1.25 for mine-run, but there is a great deal of coal available in the market at much less than that figure. Spot prices are generally about $1, and considerable business has been negotiated at 80c. with some down to 75c. These fluctuations are naturally affecting contract negotiations adversely.

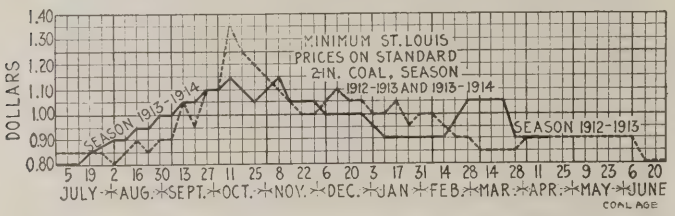
There has been little coal come in from the Hocking district that arriving being quickly disposed of. Splint coal is slightly stiffer as the result of restricted shipments, and the same conditions prevail on Eastern Kentucky which is quoted at $1.75. Particular disappointment is felt over the screening situation, a strong market having been anticipated during the spring and summer on this grade. It is rather remarkable, but nevertheless it is a fact that with practically all mines shut down the price tendency still continues downward.

The only department in which any improvement is noticeable is in the byproduct coke, several fairly good contracts having been closed. Gas house coke for prompt shipment is weak; although nominally it sells at $4.25, sales are reported at reductions of 10 and even occasionally 20c. per ton. Furnace and foundry coke are dull.

The Chicago market is now quotable on the following basis:

	Springfield	Franklin Co.	Clinton	W.Va.
Domestic lump.....	$2.07	$2.30@2.40	$2.12	
Steam lump.....	1.97		1.97	
Egg.....		2.30@2.40		$3.65
Mine-run.....	1.87	2.15@2.25	1.87	3.30
Screenings.....	1.67	1.85@1.95	1.62	

Coke—Connellsville and Wise County, $5 and $5.25; byproduct egg, stove and nut, $4.45; gas house, $4.25.



ST. LOUIS

Operations at a complete standstill. Plenty of coal available and prices continue weak. Colder weather stimulates demand.

Trade conditions in and around St. Louis are absolutely at a standstill. Over in the Illinois field a few coöperative mines are working and here and there a railroad mine, and a few commercial mines. These operations are all, as a rule, in the fifth and ninth districts, which shows that the

attitude of the operators in these districts is to cater to the miners instead of holding out with the producers from the other districts. In the Williamson-Franklin field a few mines started up and worked for a day or two, but operations are practically suspended now. There is plenty of coal on track, especially lump and egg, the only scarcity being for the nut and steam sizes.

In spite of the possibility of a prolonged shut down, coal is still being sold below or at the cost of production in all fields. Standard 2-in. lump is offered as low as 85c. and mine-run at 80c. Screenings, however, are selling for as much as mine-run, and will likely be worth as much as lump in the course of a few days. Franklin County coal is down to $1.15, while the average price for Carterville is $1.25. The low Franklin County price is made by a couple of jack-legged operators in that field the regular circular for that grade being from $1.25 to $1.35 from the better operations.

A small tonnage of anthracite has moved into the St. Louis market in the past week, but the smokeless and coke trade are at a standstill. During the past week the weather has been wet and chilly, causing an unusual demand at this season upon the retailers, who have found business good in small lots only. The future as regards local conditions is an uncertainty.

There is no material change from the prices of last week, with the exception of screenings, which in the Standard field are bringing 75 to 85c., and in the Carterville field 90c. to $1, with little offering. There is no washed coal on the market at all.

KANSAS CITY, MO.

Market continues practically unchanged, although showing a slightly improving tendency.

Unseasonable weather has stimulated domestic business to some extent and most of the operators in this field were a trifle more active than they had expected. The outlook is still serious for shaft operators, shovel mining in the Pittsburg field being at its height, with weather conditions favorable for this class of work. The shaft operators, however, are disposing of most of their output without serious difficulty at present, steam demand showing particular strength.

PORTLAND, ORE.

Prices on Utah and Rock Springs coals in wholesale lots reduced. Retail business light now that mild weather has set in.

Local coal dealers received word this week that the price on Utah and Rock Springs coal have been reduced on car-load lots. The reductions are 50c. per ton on Utah lump, bringing the price to $2.25 per ton, and to $1.75 per ton for egg coal. The reduction on the Rock Springs coal is 25c. per ton on lump and 50c. on nut, leaving the price at $2.50 for lump and $2 for nut. While these reductions have not yet affected retail prices, it is supposed that they will mean the announcement of summer prices in the near future. The weather being mild, with summer rapidly approaching, the demand for coal for domestic purposes is light.

FOREIGN MARKETS

GREAT BRITAIN

Apr. 3—The market continues to gain strength, and all classes of coal are well booked for early shipment. Sellers are firm in their ideas of price for forward loading, as it is anticipated that a continuance of the strike in Yorkshire will result in a heavier demand for Welsh Coal. Prices are approximately as follows:

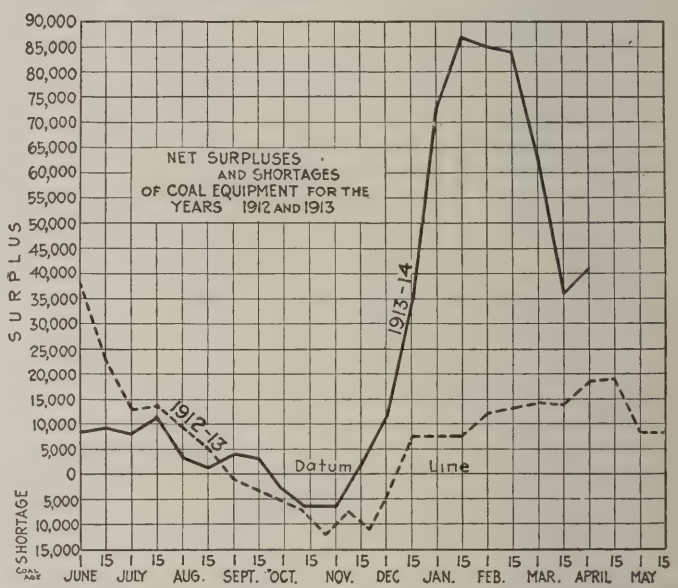
Best Welsh steam	$4.56	Best Monmouthshires	$4.14
Best seconds	4.32	Seconds	4.05
Seconds	4.23	Best Cardiff smalls	2.73
Best dry coals	4.20	Seconds	2.58

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are net f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days.

COKE

Special foundry	$6.36@$6.72
Good foundry	5.52@ 6.00
Furnace	4.92@ 5.28

PRODUCTION AND TRANSPORTATION STATISTICS



THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Apr. 1, as follows:

Index of Coal Literature

We will furnish a copy of any article (if in print) for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be sent with order.

ACCIDENTS AND THEIR PREVENTION

Monthly Statement of Coal-Mine Fatalities in the United States, December, 1913, with Revised Figures for Preceding Months. Albert H. Fay. Bureau of Mines; 23 pp.

The Prevention of Accidents in Mines. Chas. P. McGregor, Coal & Coke Op., Mar. 12, 1914; 2 pp. 20c.

BLASTING, EXPLOSIVES

Heat Test as Applied to Explosives. (First report of the Departmental Committee.) Iron Coal Tr. Rev., Mar. 30, 1914; 1¼ pp. 40c.

Permissible Explosives Tested Prior to Jan. 1, 1914. Clarence Hall. Bureau of Mines, Tech. Paper 71; 7 pp.

Production of Explosives in the United States During the Calendar Year 1912. Albert H. Fay. Bureau of Mines, Tech. Paper 69; 4 pp.

Self-Testing Electrical Shot-Firer. Coll. Guard., Mar. 13, 1914; ½ p., illus. 40c.

BORING AND TUNNELING

Air-Hammer versus Rotary Drills. Pol Dunaime. Coll. Engr., April, 1914; ⅝ p. 35c.

Air Consumption and Maintenance Cost of Rock Drills. Chas. C. Hansen. Comp. Air Mag., March, 1914; 1¾ pp., illus. 20c.

Hammer vs. Piston Rock Drills. Coll. Engr., April, 1914; 1⅝ pp., illus. 35c.

BRIQUETTES

Commercial Development of the Briquetting Industry. Chas. T. Malcomson. Coal Dealer, April, 1914; 1 p. 20c.

Use of Napthalene in Coal Briquettes. Berg. Grahn. (Translated from Glückauf.) Coll. Engr., April, 1914; ½ p. 35c.

COAL DUST

Moistening Coal Dust. Jas. L. Davidson. Coll. Engr., April, 1914; 2½ pp. 35c.

German Coal-Dust Precautions. Dr. Tornow. Coll. Engr., April, 1914; 10⅓ pp., illus. 35c.

COKE

Analysis of Coke. Coll. Engr., April, 1914; ⅓ p. 35c.

A Large Koppers' Regenerative Coke-Oven Plant in Great Britain. Coal Age, Mar. 28, 1914; 1½ pp., illus. 10c.

The Automatic Control of Byproduct Coke-Oven Plants —IV. (Thermometers and Pyrometers.) A. Thau. Gas Wld., Mar. 7, 1914; 1¼ pp., illus. 40c.

The Manufacture of Byproduct Coke. T. V. Salt. Jour. West. Soc. of Engrs., February, 1914; 30 pp., illus. 60c.

Vertical Retorts and Conveying Machinery at Leicester. Gas Wld., Mar. 28, 1914; 1½ pp., illus. 40c.

COMPRESSED AIR

Moisture in Compressed Air. Frank Richards. Power, Apr. 14, 1914; 2 pp., illus. 15c.

Some Efficient Compressed-Air Plants in Coal Mines. S. W. Symons. Coal Age, Mar. 14, 1914; 3¾ pp., illus. 10c.

The Efficiency of an Air Compressor in Mine Operations. Min. & Eng. Wld., Mar. 14, 1914; 1 p. 20c.

DRAINAGE, PUMPING, ETC.

A Mammoth Mine Pump. (Built for a service of 2500 gal. per minute against a 750-ft. vertical head.) Coal Age, Apr. 4, 1914; 1¼ pp., illus. 10c.

Combined Air-Lift and Pumping System. Lewis Jones. Coal Age, Apr. 4, 1914; 2 pp., illus. 10c.

Electric Pumping at Tilmanstone Colliery. Coal Age, Apr. 4, 1914; 3½ pp., illus. 10c.

Stripping a Mine by Hydraulic Methods. P. J. McAuliffe. Coal Age, Apr. 4, 1914; 1 p., illus. 10c.

Self-Starting Motors for Mine Pumps. W. H. Easton, Coal Age, Apr. 4, 1914; 1 p., illus. 10c.

The Proper Choice and Care of Mine Pumps. C. W. Crawford. Coal Age, Apr. 4, 1914; 1 p. 10c.

The Principle of the Centrifugal Pump. J. D. Cone. Coal Age, Apr. 4, 1914; 2 pp., illus. 10c.

ELECTRICITY

Brush-Shifting Polyphase Motor. Coll. Engr., April, 1914; 1 p., illus. 35c.

Electric Circuit Testing. Sci. & Art of Min., Mar. 28, 1914; 2 pp., illus. (to be continued). 40c.

Electric Switches for Use in Gaseous Mines. H. H. Clark and R. W. Crocker. Bureau of Mines, Bull. 68; 31 pp., illus.

Electrical Equipment for Low-Energy Consumption. (Paper read by J. Glynn Williams before the Assn. of Min. Elec. Engrs.) Iron Coal Tr. Rev., Mar. 6, 1914; ¾ p. 40c.

Fire Protection for Electrical Equipment. Lewis H. Eddy. Eng. & Min. Journ., Mar. 21, 1914; 1 p., illus. 25c.

Mine Substations—II. Motor-Generator Sets vs. Synchronous Converters. Will M. Hoen. Proc. Amer. Inst. Elec. Engrs., April, 1914; 6¼ pp., illus.

Mine Substations—I. Their Construction and Operation. H. Booker. Proc. Amer. Inst. Elec. Engrs., April, 1914; 5½ pp.

Mine Duty Controllers. Harrison P. Reed. Proc. Amer. Inst. Elec. Engrs., April, 1914; 12 pp., illus.

Power Economics for Intermittent Loads. (Paper by E. I. David read before the Rugby Eng. Soc.) Iron Coal Tr. Rev., Mar. 27, 1914; 3¾ pp., illus. 40c.

Selection of Induction Motors. C. A. Tupper. Coll. Engr., April, 1914; 2¾ pp., illus. 35c.

Explosions

The Air Factor in Mine Explosions. John Verner. Coal Age, Apr. 11, 1914; 1¾ pp. 10c.

FUEL TESTING

Helium in Firedamp and and Radio-Activity of Coal. Coll. Guard., Mar. 27, 1914; ⅓ p. 40c.

The Absorption of Gases by Coal. (From Comptes Rendus.) Coll. Guard., Mar. 27, 1914; ⅓ p. 40c.

GENERAL

A Triangulation Survey of the Fairmont Region. A. W. Hesse. Coal Age, Apr. 11, 1914; 3¾ pp., illus. 10c.

The American Coal Industry; Its Risks, Reserves and Trust Relations. A. T. Shurick, Eng. Mag., April, 1914; 3 pp. 35c.

Austro-Hungarian Iron, Steel and Coal Industry in 1913. Iron Coal Tr. Rev., Mar. 13, 1914; ⅓ p. 40c.

Buying Coal on Specification. F. G. Lemke. Power, Apr. 14, 1914; ½ p. 15c.

Burning Pulverized Coal. (Experience of the American Iron & Steel Co. in burning pulverized coal in its metallurgical furnaces.) Iron Tr. Rev., Apr. 9, 1914; ½ p. 25c.

Coal Industry of the British Empire. (From the annual Statistical Abstract for the British Empire issued by the Board of Trade.) Iron Coal Tr. Rev., Mar. 13, 1914; ½ p. 40c.

Dwelling Houses at the L. C. & N. Co.'s New Hauto Plant. (Hollow tile is used in the erection of these houses.) E. L. Kellogg. Coal Age, Mar. 28, 1914; 1¾ pp., illus. 10c.

Coal-Mining Operations in Belgian Collieries. (Translated from Annales d. M. de Belgique.) Coll. Guard., Mar. 13, 1914; 1¼ pp., illus. 40c.

Founding a Building over Coal-Mine Workings. Geo. E. Stevenson. Eng. News, Apr. 9, 1914; 1½ pp., illus. 25c.

Fifteenth Annual Report of the Mining Industry of Idaho for the Year 1913. Robt. N. Bell. 114 pp., illus.

Flooded Coal Mine in Illinois. Frank Rosbottom. Coll. Engr., April, 1914; 1 p. 35c.

Important Details in Construction of Colliery Plants. (Paper by M. L. Hyde read before the Can. Min. Inst., February, 1914.) Coal Age, Mar. 21, 1914; 8 pp., illus. 10c.

Insurance on Mine Property. W. H. Charlton. Coll. Engr., April, 1914; 2 pp. 35c.

Methods of Weighing and Computing Mine Outputs. Neill Hutchings. Coal Age, Apr. 4, 1914; 2 pp. 10c.

Nationalization of Mines and Minerals. (Paper by Prof. Henry Louis read before the Economic Soc., Feb. 25, 1914.) Iron Coal Tr. Rev., Mar. 6, 1914; 2⅓ pp. 40c.

Principles of Efficiency for Mine Management. (Abstract of paper read by G. A. Collins before the Pacific Northwest Soc. of Engrs.) Min. & Eng. Wld., Apr. 4, 1914; 3 pp. 20c.

The Combustion of Coal and Smoke Abatement. (Paper by S. B. Flagg read before the Cleveland Eng. Soc., Mar. 10, 1914.) Coal & Coke Op., Apr. 2, 1914; 3⅓ pp., illus. 20c.

Third Annual Report of the Director of the Bureau of Mines. Joseph A. Holmes, Bureau of Mines, June 30, 1913; 106 pp.

The Advancement in Bituminous Coal Mining. (Address of S. A. Taylor before the Engrs. Soc. of West Penn.) Proc. Engrs. Soc. of West. Penn., January, 1914; 60 pp., illus. 60c.

Uniformity in Inspectors' Reports. Rufus J. Foster. Coll. Engr., April, 1914; 2 pp. 35c.

GEOLOGY

The Ching Hsing Coal Basin. Edward Di Villi. Min. & Sci. Press, Apr. 4, 1914; 1 p., illus. 20c.

The Occurrence of Coal in Squaw Creek Basin, Coos County, Oregon. Ira A. Williams. Min. Resources of Ore., Vol. 1, No. 1; 23 pp., illus.

The Pittsburgh Coal Bed. W. G. Burroughs. Coal Age, Mar. 14, 1914; 2½ pp., illus. 10c.

Conditions Affecting Mining. (Relates to the Bering River and Matanuska coal fields of Alaska; folded and faulted coal beds with irregular cleatage and much water.) W. R. Crane. Coll. Engr., March, 1914; 4¾ pp., illus. 35c.

Coal Fields of Jasper Park, Alberta. Frank E. O'Neal. Coll. Engr., February, 1914; 3⅓ pp., illus. 35c.

Hisylvania Mine 23. (Geology of the Hocking Valley and description of mining methods used in the Sunday Creek, Ohio coal field.) W. G. Burroughs. Coll. Engr., February, 1914; 3½ pp., illus. 35c.

HOISTING AND HAULAGE

Some Advantages of the Electric Hoist over the Steam or Air Hoist. K. A. Pauly. Gen. Elec. Rev., April, 1914; 6 pp., illus. 30c.

The Development of the Electric Mine Locomotive. G. M. Eaton. Proc. Amer. Inst. Elec. Engrs., April, 1914; 22 pp., illus.

The Electrical Driving of Winding Engines and Rolling Mills. (Abstract of a paper read by C. Anthony Ablett before the Can. Soc. of Civil Engrs.) Can. Min. Jour., Apr. 1, 1914; 6½ pp., illus. (To be Continued.) 25c.

LEGAL REFERENCES

An Analysis of the Commerce Law. Sydney A. Hale. Coal Age, Mar. 14, 1914; 3 pp. 10c.

Pertinent Supreme Court Decision, Affecting Mine Cave Problem. (Editorial.) Coal Age, Mar. 14, 1914; ¾ p. 10c.

Rescue Corps at a British Colliery

The First Trained Rescue Team in Western Canada

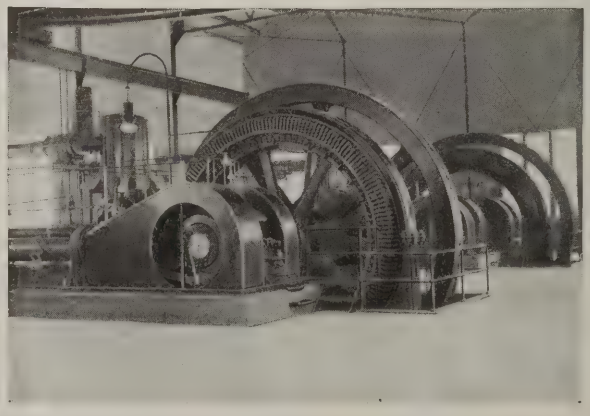
This is an end view of a Westinghouse Electric Synchronous Motor. It is interesting to mining men because these motors provide

The Most Satisfactory Drive for Air Compressors

They can be direct-connected to the compressor and hence **cost less to install** than belted drives and require less floor space. Belt maintenance expense and transmission losses are eliminated.

The first cost is about the same as for other types of drive for compressors of 1000 cubic feet per minute capacity. For larger sizes, it is less.

The efficiency is higher than that of any other type of drive and the high power factor at which these motors can be run improves the operating characteristics of the entire circuit.



The great reliability of these motors is proved beyond all question by successful installations in all parts of the country.

Send for full description of these motors.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication. Subscription price $3 per year, in advance, for 52 numbers to any postoffice in the United States or possessions, and Mexico. $4 to Canada.

Published Weekly By HILL PUBLISHING COMPANY
505 Pearl Street, New York, N. Y.

JOHN A. HILL, Pres. ROB'T MCKEAN, Sec'y.

Cable Address, "COAGE," N. Y.

$5 or its equivalent to any other foreign country. Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London Office, 6 Bouverie St., London, E. C., England.
Notice to change address should be written to the New York Office in every instance.
Advertising copy should reach New York Office by Thursday of week prior to date of issue.
Entered as second class matter, October 14, 1911, at the Postoffice at New York, New York, under the Act of March 3, 1879.

VOLUME 5 APRIL 25, 1914 NUMBER 17

CONTENTS

WITH PRINCIPAL ARTICLES SUMMARIZED.

*Illustrated Article

FOREWORD: *Page* 673

Some companies are endeavoring, through welfare work, to establish a business based on friendship. This causes the employee to feel that he is too much the ward of the company. Welfare work to be successful should never savor of charity to the men. Don't do welfare work as the means to an end.

*PROBLEMS ENCOUNTERED IN KENTUCKY COAL MINING: *Pages* 674-676

In the west Kentucky coal field about 66 per cent. of the coal is extracted, and in some places only 44 per cent. The roofs of the beds are weak, but coal is left in mining to protect the miner. As a result of this, and other care, the death rate is less than one fatality for 790,000 tons. Gob fires give much trouble. Newell G. Alford. COAL AGE, Vol. 5.

NEW MINING LAW IN KENTUCKY: *Pages* 676-677

*ANTHRACITE COLLIERY BOILER PLANT: *Pages* 678-682

Many boiler plants throughout the anthracite region of Pennsylvania are anything but economical in their use of fuel. By the use of modern boilers, equipped with proper auxiliaries, the cost of steam may be reduced 60 per cent. J. F. McMahon. COAL AGE, Vol. 5.

AN EXTRAORDINARY EXPERIENCE: *Page* 682

THE KENTUCKY COMPENSATION ACT: *Pages* 683-684

A review of the salient features of the Workmen's Compensation Act recently passed by the Kentucky Legislature, with particular reference to its bearing on the coal operations of the state. COAL AGE, Vol. 5.

*A METHOD OF MEASURING GOAF TEMPERATURES: *Pages* 684-685

A description of the construction and application of a new instrument for measuring goaf temperatures, together with certain tests relating thereto. The device exhibits increased electrical resistance on any rise in temperature. T. F. Winmill. COAL AGE, Vol. 5.

*A SMALL PORTABLE ELECTRIC HOIST: *Page* 685

EXAMINATION QUESTIONS WITH ANSWERS: *Page* 702

COAL AND COKE NEWS: *Pages* 703-706

ACCIDENT FREQUENCY AMONG ENGLISH-SPEAKING MEN AND OTHERS: *Pages* 686-687

Only in West Virginia are statistics on this subject available. The Germans appear to have the highest nonfatal accident rate. It seems established that the Italians and Negroes take less care of themselves than the American whites. Howard I. Smith. COAL AGE, Vol. 5.

*LONGWALL IN SEAMS LIABLE TO SPONTANEOUS COMBUSTION: *Pages* 687-688

Working a seam at South Derbyshire, England, where the coal is liable to spontaneous combustion. Several attempts to prevent the ignition of the coal by excluding the air from the waste proved unsuccessful, until the adoption of the longwall system of mining. J. E. Spicer. COAL AGE, Vol. 5.

*AVAILABILITY OF THE CEMENT GUN FOR MINE WORK: *Pages* 689-692

The cement gun deposits cement mortar by an air blast, mixing the water with the dry ingredients at the delivering nozzle. The material formed is known as gunite and is denser and stronger than ordinary cement mortar or concrete. It is well suited for making buildings fireproof and permanent, and for coating headframes, tipples and mine roadways. COAL AGE, Vol. 5.

THE TRAITOR: *Page* 692

Poem by Berton Braley. COAL AGE, Vol. 5.

*AUTOMATIC SAFETY MINE-CAR CAGERS: *Page* 693

E. G. Banta. COAL AGE, Vol. 5.

WHO'S WHO IN COAL MINING: *Page* 694

Brief sketches of the lives of E. V. d'Invilliers, geologist and mining engineer of Philadelphia, and William Haven, formerly manager of the Inland Fuel Co., Charlton, Iowa.

EDITORIALS: *Pages* 695-696

One Way to Introduce Your Coal—Manyana—The Operators of Central Pennsylvania—One Great Item of Cost in Mining—Rules, General and Special—The 100-Per Cent. Union—The Saloonstead.

DISCUSSION BY READERS: *Pages* 697-699

Starting Longwall in Room-and-Pillar Work. Letters Nos. 1 and 2.

STUDY COURE IN COAL MINING: *Pages* 699-700

INQUIRIES OF GENERAL INTEREST: *Page* 701

Room-and-Pillar System vs. Longwall—*Laying Out Mine-Track Curves.

Advertising Is Not A Tax

The Weekly Ad-Talk Page

Who pays for the advertising—the buyer or the advertiser?

Perhaps many of you have long waited for an answer to this question. Perhaps you have heard it answered before—both ways.

Our answer is that the advertiser pays for the advertising, and it in turn pays both you and the advertiser.

The fact that the advertised article usually costs less, whether in first cost or ultimate cost, than the unadvertised article, proves the truth of the statement that you do not pay any part of the advertising costs of any article you buy.

The big department store which has the most popular corner in your city pays an enormous rent when compared to that which the little fellow pays on the side street—and yet you pay no more for the article you buy in the big store (usually you pay less) than you do for the same thing in the small store, which pays small rent.

Therefore you are not taxed for any part of the difference in rent between that which the big store on the corner pays and that which the little store pays on the side street.

The former can afford to pay big rent because his location, among other things, is the big factor in drawing the trade. His profit may be less on the individual article, but in the aggregate it is more—because he *sells* more.

And so it is in advertising. The concern which advertises is the concern which can *afford* to give you a better article at a better price than can the concern which does not advertise at all.

This point was well illustrated a few months ago when the writer took a chance on some merchandise, at the merchant's advice that the brand he had was "just as good" as what was asked for, and that it was cheaper "because the manufacturer did not advertise, and hence did not have to pay any advertising costs."

Yes, it was cheaper—both in price and quality, but mostly quality; as it did not give 50% of the wear and service of the advertised brand.

You will find the same conditions in the technical field. The concern which advertises its wares week after week must make good *both* in price and in quality, for the reason that he has more investment and more prestige at stake than does the concern which stays in its shell out of sight of the distant buyer.

And because he does advertise, he sells more. His profits in the aggregate are more, and thus he can meet competition without taxing *you* for any part of his advertising costs.

Go to the Selling Section of COAL AGE when *you* want equipment for plants in the coal mining field. You'll find the competition keen, the prices right, and service the best.

COAL AGE

Vol. 5 NEW YORK, APRIL 25, 1914 No. 17

It is a saying of one of the richest men in America, the head of a great industrial corporation, that:

"A Friendship founded on Business is a good deal better than a Business founded on Friendship."

Most concerns have learned the value of service; that is, following up the goods sold to see that the customer is not only satisfied with his purchase, but that whatever is necessary in the way of advice as to the best use and operation of the articles bought, together with all essential repair parts, etc., is constantly and easily obtainable.

That is SERVICE and it makes friends as the result of good business.

A good many coal-mining companies nowadays are making SERVICE an integral part of their operations by doing "Welfare Work" which consists of service to employees through making living conditions in mine camps and towns more desirable by reason of proper housing, sanitation, etc. Also by making life in such camps and towns more like life should be, in the way of providing churches, schools, playgrounds, baseball and tennis grounds, moving-picture halls, etc. In fact to make a mine camp or town as attractive and desirable a place to live as anywhere else.

This welfare work is good. Without doubt it is responsible for improved living conditions in many coal-mining communities. The cost of it is nearly all borne by the companies engaged in the work. Yet, welfare work still has many critics, and, strange to say, most of these are among the very employees for whose benefit such work is being done. What is the basis of this criticism and how can the companies that are honestly trying to improve conditions for their employees and familes, overcome it?

The answer to the first question is that some companies are endeavoring, through welfare work, to establish a business based on friendship, which they hope to secure through this medium. The welfare work they do is played up so strong and is so much advertised, that the employee is led to believe that he is too much the ward of the company, and that after all whatever Charity—as he terms it—the corporation bestows on him in the way of welfare work, it got out of him down in the mine.

Sometimes too this is true as in the case of one model mine camp we recall, where everything on the surface from tenements, church and schoolhouse to steel tipple, was so pretty, that men on going there to seek work turned away, saying "Nothing doing—it's too d—n nice on top." Certainly that sounded like these men had been to places where the inside was neglected for the benefit of the outside.

The answer to the second question is that while criticism of welfare work will possibly never be entirely overcome, because of the instinctive belief the miner has that when you do so much of this kind of thing for him, you are striking at his independence somewhere; it can in large measure be overcome by making the welfare work a company does, as much an integral part of its operations as running pumps and motors. To persist in it through good times and bad, yet never to let it savor of Charity to the men. In other words to conduct the business so that friendship follows.

After all it is simply a matter of following the right principle, for it is next to impossible for men to be proof against good treatment when they are convinced that there is no ulterior motive. But the most lavish welfare work will finally be of no avail if the wages, conditions and treatment of men in and about the mine itself are not equally as good and even better in kind than the welfare work itself. In other words, don't do welfare work as the means to an end. If this principle governs the conduct of it, you may as well not do it.

Problems Encountered in Kentucky Coal Mining

By Newell G. Alford*

SYNOPSIS—In the west Kentucky coal field about 66 per cent. of the coal is extracted and in some places only 44 per cent. The roofs of the beds are weak, but coal is left in mining to protect the miner. As a result of this and other care the death rate is less than one fatality for 790,000 tons. Gob fires give much trouble.

In the latest available reports of the Kentucky mine inspector and the United States Geological Survey's "Production of Coal in 1912," it is estimated that the total coal acreage of the state is approximately 16,670 square miles, of which the western Kentucky coal field embraces 38.3 per cent.; also that Kentucky's coal production in 1912 was 16,491,000 tons, 47.7 per cent. of which was produced in the western field.

This 47.7 per cent., which amounts to slightly less than 8,000,000 tons, was produced by 120 mines, operated by 98 companies. I have made a detailed classification of these 120 mines and their outputs as follows: 21 per cent. produce less than 10,000 tons; 51 per cent. produce less than 60,000 tons; 23 per cent. produce more than 100,000 tons; two companies operating 18 mines, produced 2¾ million tons.

Coal Beds Worked

The workable coal beds in the western Kentucky field, under development, are with but a few exceptions No. 9 and No. 11 as identified by the Kentucky State Geological Survey. Being more consistent in occurrence, No. 9 supplies about three-fourths of the total output of the field. This seam, which is present in eight counties, averages 5 ft. in thickness. While this bed is most generally approached by shafts 300 ft. or less in depth, there are depressions in some vicinities which make entrance possible by slope or drift.

Seam No. 11, which is from 40 to 100 ft. above No. 9, is the next bed of importance in this field. It averages 6 ft. in thickness.

Room-and-Pillar Workings

Without exception, the mines of western Kentucky are developed by the room-and-pillar method, with double or triple entries. The triple-entry system is used only in the larger mines. There the motor parting is made in the central entry; the side entries are used for mule haulage and ventilation, respectively. This not only facilitates ventilation, but permits of the motor parting being placed nearer the working rooms, thus reducing the mule haulage. This efficiency is gained, however, only at the increased cost of driving an extra entry.

Robbing pillars in No. 11 coal is particularly hazardous and impracticable because of the heavy, solid limestone roof. No. 11 coal is friable and crushing results where insufficient pillars have been left. Moreover, the pillars settle under pressure with the consequent heaving of the soft, fireclay bottom.

In some of the mines in this field, old works are used as air courses. Gases generated from gob and shale piles are absorbed and carried along by the air current.

The difficulties arising from this practice indicate that it should be avoided in all cases, for the numerous wooden brattices to be maintained make it impossible to prevent large leakages in the current. In addition to this, the friction resulting from the large rubbing surfaces encountered necessitates an increase in the horsepower of the ventilating equipment.

An instance is referred to, in the territory under discussion, where within the last few years an old mine was abandoned. The intake air was delivered by way of a long, circuitous route through old workings to the working faces. Owing to the long distance which the air had to travel, it finally reached the faces so permeated with impurities that its vitiated condition became one of the causes for the closing of the mine.

Ignition of No. 11 Coal in Old Workings

Seams No. 9 and No. 11 with their accompanying shales and gob roof are highly charged with iron pyrites. The atmospheric oxidation of the iron pyrites in the pillars of old works accounts for the generation of much heat, slow as the process may be.

It is also believed that the energy expended in crushing pillars of insufficient size, by the overlying strata, is transformed into heat which promotes a rise in temperature.

The consequent expanding of the coal produces crevices which in turn augment oxidation. Gradually after smoking awhile the coal breaks into a smoldering fire, the boney roof ignites and falls, and this is followed by the ignition of No. 12 coal, where the intermediate stratum of limestone is absent. This last development occurs where the fire has gained sufficient headway.

The prevention of such fires presents an interesting problem, which is solved by sealing off the works liable to such chemical action; or by increasing the quantity of circulating air.

The pursuance of the first method is a popular one because it not only prevents spontaneous combustion, but avoids the impregnation of the circulating air with the gob or shale gases. Since this method can best be worked out by sealing up an entire block of old workings after their abandonment, it has created a tendency on the part of the largest operator in the field to adopt the panel system in working No. 11 coal. To brattice off the old works largely excludes the oxygen necessary to the oxidation of the iron pyrites.

The second scheme is important because conditions arise where it is impossible to follow the sealing-off method. Here the end is accomplished through reducing the temperature of the air in contact with the pillars, by increasing the quantity in circulation and thus preventing the development of heat.

Coal Dust

In workings where there is a scarcity of mine water, the accumulation of coal dust is, in most cases, given the close attention of the various managements. In keeping

*Assistant engineer, St. Bernard Mining Co., Earlington, Ky.

Abstract of a paper presented at the winter meeting of the Kentucky Mining Institute, Dec. 8, 1913.

with the usual practice, coal dust is cleaned up at intervals and hauled from the mines. Sprinkling is also in prevalent usage in this connection. Humidification of the intake air in the winter months has been universally adopted by the larger operators.

Shooting Off the Solid

Because of the dangers attending the shooting of coal from the solid, Chief Inspector Norwood has repeatedly discouraged this practice. In his report of 1891, he comments in part as follows:

"Shooting off the solid is less common now than a few years ago, when the prevalence of this practice called for a warning from this office. Coal dust is now (speaking of 1891) generally admitted by those who have studied the question, to be almost as dangerous as firedamp. An explosion may occur in any dusty mine and one is to be expected where shooting off the solid is practiced."

When unsupported, the roof of the working places in the No. 9 seam presents a great hazard to the life of the workman. Only by careful inspection and thorough propping, can accidents be avoided. As workings approach crop lines the liability of accident becomes even greater, since the black slate here shows marked tendencies toward disintegration.

In the No. 11 seam, the bone roof, between the coal and the limestone, is even more dangerous than the slate roof of No. 9. After the coal has been shot down, the bone roof will overhang the working places in thicknesses varying from 4 to 30 in. Being exceedingly treacherous, it will work downward from the limestone cover and fall without warning.

One of the large operators has the coal cut by hand in the workings of those entries where the roof is such as to necessitate propping too close for the operation of a coal-cutting machine.

The West Kentucky Coal Field

Thus, almost two decades prior to the scientific investigations and experiments conducted to prove that coal dust was an explosive agent, the chief inspector of Kentucky, together with other advanced thinkers, declared that dangers were attendant upon the presence of coal dust in our mines.

In connection with shooting coal from the solid, it is worthy of note that the machine-mined coal in western Kentucky was 26 per cent. of the field's output in 1895; in 1911 it was 79 per cent., an increase in 16 years of 53 per cent. In Hopkins County, the largest producing county of the state, 2,550,000 tons of coal were mined in 1912, 99 per cent. of which was undercut by machines

Accidental Death Rate Low

It is to the credit of the mine inspectors and mine managers alike, that the last report shows an unprecedented increase in the amount of coal mined per fatal accident. In 1910 there were 159,033 tons of coal won for each life lost. In 1911, the production per fatality was 790,222 tons.

Overlying these coals is from 10 to 15 ft. of light-gray shale, which is in the advanced stages of disintegration. On removing all the coal, the shale will fall to heights of 6 to 8 ft.; 12 to 18 in. of coal is, therefore, left overhead as a roof, of which 60 per cent. is reclaimed in the rooms after they have been exhausted. When the coal is mined to its full thickness the rotten overlying shale requires timber sets, thoroughly and solidly lagged, to hold it. In all entries no attempt is made to reclaim this top coal.

The degree of caution exercised within the mines in this field by superintendents and foremen is reflected in the following accident list:

During the year 1911, in the entire western Kentucky field there were only three fatal accidents from falls of roof, and 19 minor or nonfatal accidents from the same cause.

Coal Recovery 66 Per Cent.

A fair estimate fixes about two-thirds as the net proportion of coal which is won from the mines. Excessive competition in this field leaves so small a differential between

costs of production and sales prices that crop coal, and coal of more expensive excavation must be left untouched and forever lost. Despite decreases in the market price, the consumer becomes more exacting and much coal is wasted at the tipples in cleaning the product to make the grades salable at even a small figure. Good coal clinging to lumps of sulphur is often discarded on the waste piles in quantities which more than justify the lamentations of those who are sincerely interested in the conservation of our coal resources.

Excessive Loss in Cleaning

A large operator in this field discovered that in satisfying the exacting demands of his customers he was throwing away, on his refuse pile at a single mine, coal, which if properly cleaned, would have yielded him in the neighboorhood of $1000 per month. This shows that if there had been some means of preparing this coal for use, provided that the mine was operating on a very narrow margin of profit, the net value would have done much toward helping the balance on the credit side of the ledger.

Another source of waste in this district is the indifference with which some of the operators plan the future development of their property. On good authority, it is claimed that 50 per cent. of the operators have no idea as to the amount of the holdings which they have already exhausted. Coincident with this is the general scarcity of technically trained engineers.

Inadequate pillars also contribute to the general waste. Frequently the smallness of pillars results in a squeeze which necessitates the abandonment of the working places. These rooms must then be recovered by driving "cutoffs," at much additional expense. Much of this coal is ultimately lost.

It is taken for granted by most western Kentucky operators that squeezing goes hand in hand with the mining of coal. It is regarded as a necessary evil, as if it was one of the penalties of mining.

Operators working seams other than Nos. 9 and 11, in several instances, find it wholly impossible to recover more than 44 per cent. of their available coal and are required by their conditions to leave more than half of the coal unmined.

Cost Keeping

Another question needing attention in this field is that of cost keeping. It is perfectly safe to say that 75 per cent. of the operators do not know what it costs them to mine a ton of coal. They get extensions on bills and buy equipments on the instalment plan with interest. This method of doing business does not constitute bad management, but in many cases these items are not charged off in keeping with a careful accounting system. At the end of a given period the operators find their balance on either one side of the ledger or the other, but how it came about there is no telling.

The other 25 per cent. of the managers who keep detailed information on this phase of operation are those that have been producing the larger outputs.

Pond Sites

Most of the coal acreage in the western field lies inland between the Ohio and Green Rivers, and because of the flat surface, trouble is often experienced in locating reservoir sites with sufficient water sheds. In such cases, extended droughts necessitate either long pipe lines or the hauling of water in tank cars.

Competition

The conditions which tend to promote keen competition in this field deserve mention. Involuntary suspensions in other fields have in times past created a demand for western Kentucky coal in the large markets outside of its natural sale zone. Limited capital has drawn the conclusion that the lucrative mining of coal means only the sinking of a shaft or the opening of a drift. The comparative ease with which such openings are made in this field, the cheapness of coal "in place," together with short periods of spasmodic prosperity, have brought into being small operations which cannot be sustained by the normal demands of the present market.

New Mining Law in Kentucky

A bill was recently introduced by Mr. Arnett (Senate Bill No. 321, Feb. 19, 1914), in the Kentucky Assembly, and promptly referred to the Committee on Mines and Mining. The bill is a practical revision of the mining laws of the state. It passed the Assembly, Mar. 15, and became the law of the state by the signature of the governor, Mar. 23.

A Kentucky Department of Mines

Among the important changes in the state mining law, made by this enactment, is the creation of a Department of Mines and the authorization of the title "Chief Inspector of Mines," as applied to the official who shall have full charge of said department. By the law of 1891-93, mine inspection in the state was placed in the hands of the Dean of the School of Mining Engineering, of the State College, at Lexington, who then became the inspector of mines.

The Old Mining Law

By act of the General Assembly, 1906, the governor was authorized and directed to appoint two additional assistant inspectors. Two more assistant inspectors of mines were authorized by the enactment of the General Assembly, 1908. The same act provided a board of examiners for the examination of applicants for certificates of qualification to serve as mine foremen. This board consisted of the chief mine inspector and two of his assistants chosen by himself from his own staff. The same law also authorized the chief mine inspector to order the employment of shotfirers in any dangerous or gaseous mine or mines employing 10 or more persons.

By act of General Assembly, 1910, the certificates of qualification were classified as follows: A first-class certificate authorized its holder to act as mine foreman in any coal mine in the state. A second-class certificate authorized its holder to act as mine foreman in any non-gaseous mine in the state. A third-class certificate authorized its holder to act as mine foreman in any non-gaseous mine employing not more than 25 persons at one time.

Provisions of the New Law

By the new law, Act of 1914, the chief inspector of mines is authorized to divide the state into inspection districts and to assign each assistant inspector to work in his

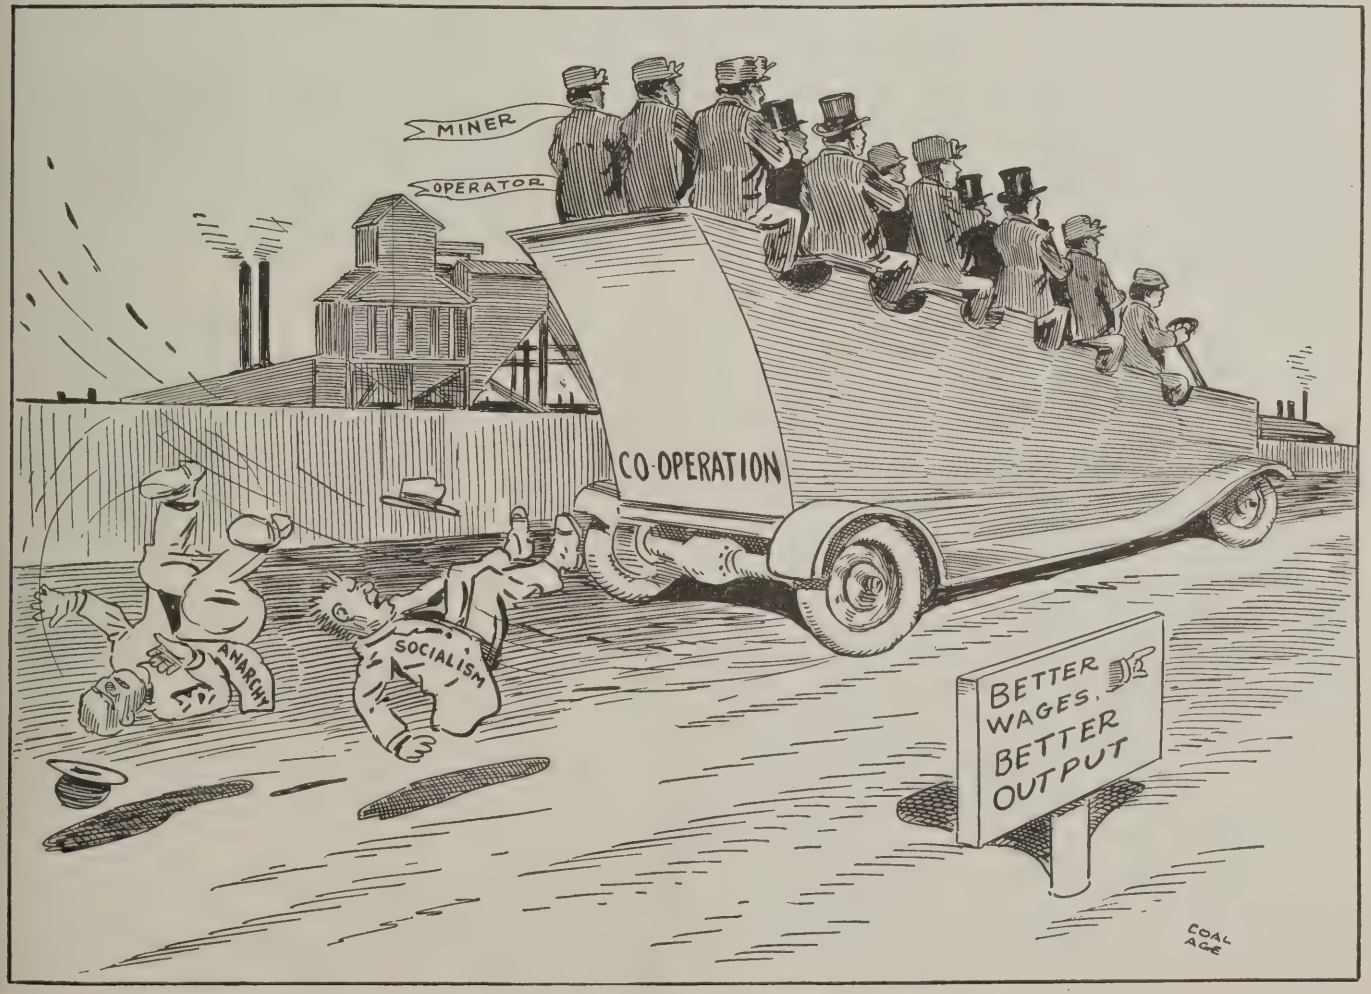
own district. The law also provides for the making of accurate maps and plans of the workings of each mine, within 60 days after Jan. 1, each year.

Personnel of the Examining Board

An important feature of the new law is the appointment by the governor of one miner who has had five years' practical experience in the mining of coal and is actually employed in mining coal at the present time, and one coal operator or his representative who is actually engaged in the operation of a coal mine in the state at the time, as members of the examining board, thus increasing the board members from three to five. The chief mine inspector is made chairman of the board and two of his assistants are of his own selection. The examining board examines all applicants for the positions of assistant inspector of mines, mine foreman and fireboss.

Another feature of the new law is the provision that no person shall be permitted to serve as mine foreman or fireboss, in any mine employing 15 or more persons at one time, except a person holding a certificate of qualification granted by the examining board, making him eligible for such position. The new law defines terms and specifies the duties of mine superintendent, mine foreman and fireboss, and contains a number of other provisions relating to ventilation, drainage, safety lamps, the firing of shots, electrical installations, first-aid supplies and the storage of oil and explosives. Many other points of importance are also included in the new law, which marks a commendable advance in the efforts to conserve our coal beds, increase efficiency and promote safety in mining.

First Aid and Accident Prevention



By A. S. Snyder*

Instruction to first-aid men should not be restricted to the rendering of first aid for injuries. Prevention of accidents is just as important a study as is how to take care of an injured man.

Those who have received instructions in first aid are usually more alive than others to the dangers surrounding mine work and more careful to avoid them. This care should be impressed on them in their training and they should be urged to report all dangerous conditions which may come under their notice to the foreman or his aides unless they can themselves remove the danger.

The saving of life is the most important of all conservation, for without human life of what use is the conservation of any natural resource—minerals, forests or what not? The prevention of accidents is profitable to everyone—to the employee, the employer, the community and above all, to those who are dependent on the wages of the employee.

Let's All Get into the Band Wagon

Anthracite Colliery Boiler Plants

By J. F. McMahon*

SYNOPSIS—Many boiler plants throughout the anthracite region of Pennsylvania are anything but economical in their use of fuel. By the use of modern boilers equipped with proper auxiliaries the cost of steam may be reduced 60 per cent.

It is an admitted fact that anthracite-colliery boiler installations seldom attain the standard of efficiency secured by public-service companies. The reason frequently ascribed for this state of affairs is that in many instances the colliery management has been incumbered with an adverse inheritance, consisting of either cylindrical, tubular, locomotive or some ancient type of water-tube boilers. These, besides being inefficient, possess disadvantageous conditions so far as fuel and ash handling is concerned, with the result that men and mules have become a constant charge in their operation. Furthermore, as the fuel consumed is ordinarily Buckwheat Nos. 2 and 3 with a more or less generous mixture of Buckwheat No. 1 in extreme conditions, it is impossible to realize even approximately the heat content of the coal.

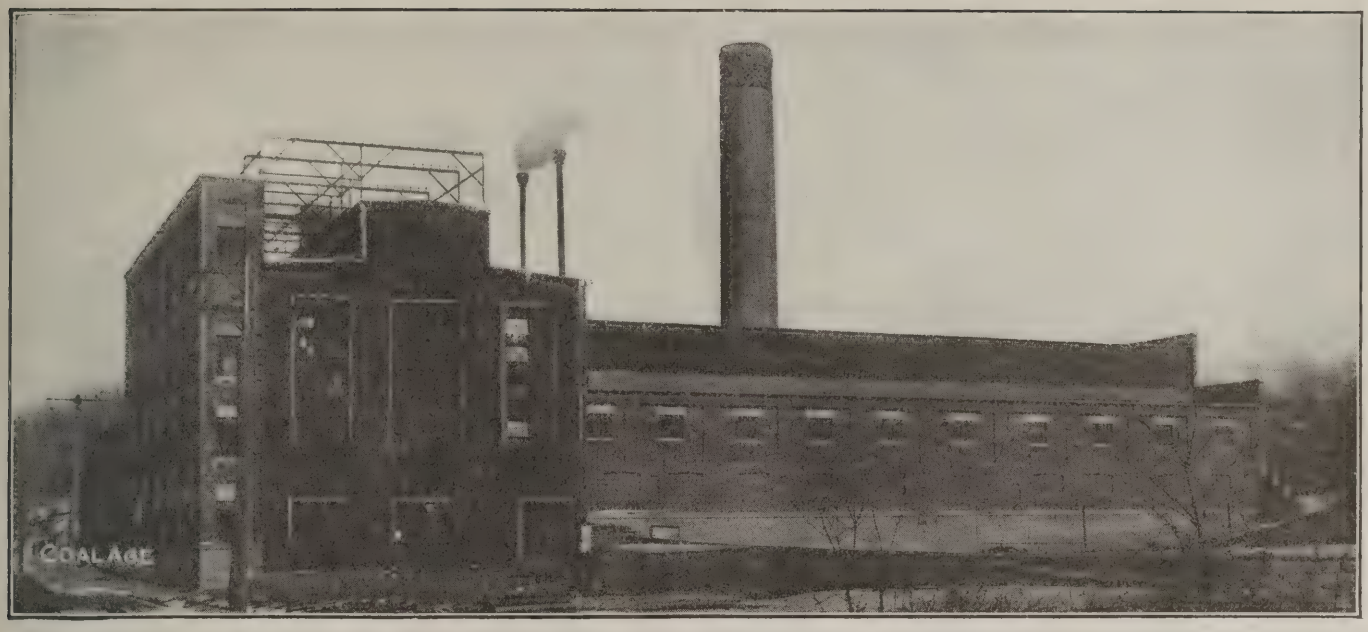
General View of an Ancient Anthracite Boiler Plant. Many Such Plants Are Still Operated

In many instances, however, such extravagant conditions and practices as exist in power plants throughout the anthracite region show either a lack of forethought or positive negligence upon the part of both engineering department and management, and unless the assured life of the colliery is extremely short, a change of equipment (upon which benefits might be realized at once) should be undoubtedly made. While cases may exist where good engineering economics would dictate that the equipment should remain in a *status quo* without remodeling or improvement, these are isolated and the general statement holds true that in most instances anthracite boiler plants might economically be made efficient and acceptable to the best present-day engineering practice.

*Wilkes-Barre, Penn.

Steam Equipment Should Be Centralized

In order to accomplish the maximum efficiency in power-plant design and operation, the entire steam-generating equipment should so far as possible be centralized in one general unit with the distribution lines radiating to the various steam consumers. Provided these lines are properly covered this arrangement is vastly superior in economy to several isolated plants.



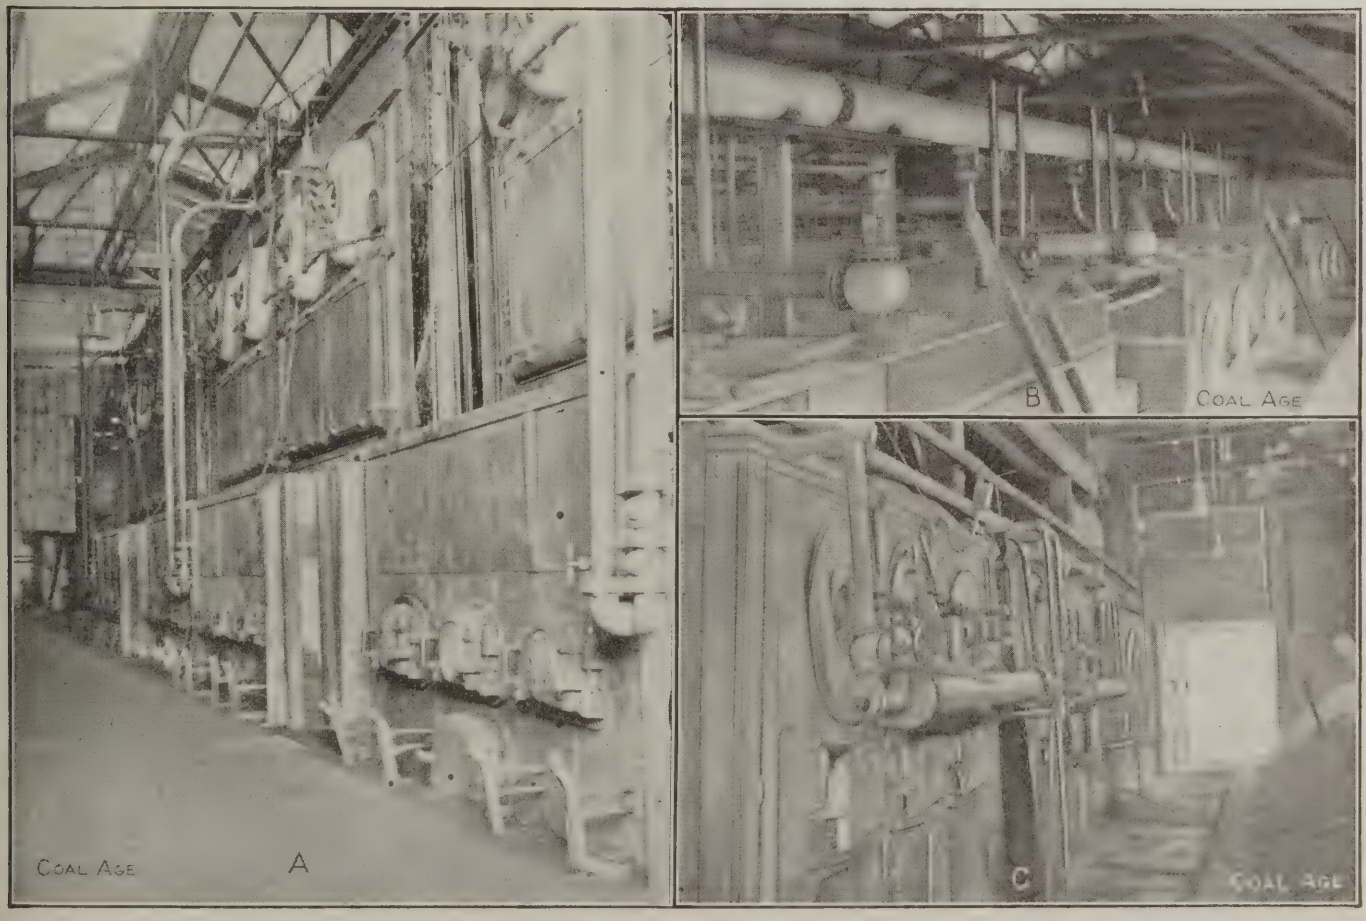
The boilers employed should be of the latest water-tube type, having a ratio of heating surface to grate area of about 25 to 1, and never exceeding 30 to 1.

The air space of the grate should be from 8 to 15 per cent. of the grate area with the openings suitable for sustaining buckwheat coal, which passes through a $\frac{3}{16}$-in. mesh and over a $\frac{1}{32}$ mesh. Sectional dumping grates, stationary grates having a discharging section or a discharge outlet in the deadplate should be employed. Regardless of whether the plant is erected new or remodeled every facility should be employed for discharging the refuse material quickly and with the least labor.

Ash disposal may be accomplished in a variety of ways. The ashes may be conveyed with water by gravity to a common point and there transferred to cars. The ash pits may discharge direct to tunnel cars, which may be disposed of in some suitable manner, or the refuse material may be disposed of by means of an overhead or aërial ash-handling equipment.

The fuel may be brought from the breakers by a conveyor line to a general overhead coal bunker or it may be brought to the boiler house in railway cars, being dumped through a tunnel or trough to a table or bench, so placed as to be most convenient to the firemen, thus eliminating unnecessary manual labor and tending toward a clean boiler room.

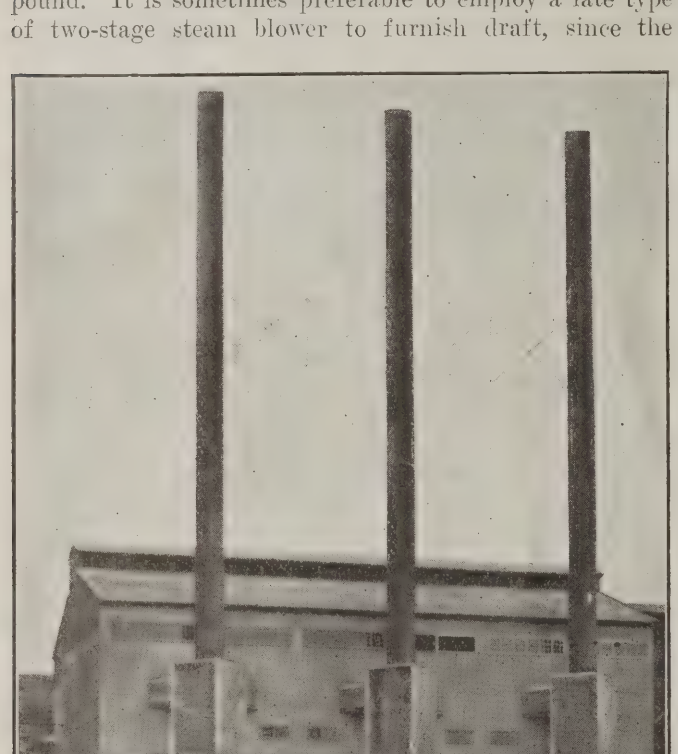
A firebrick arch, a Dutch oven, or an adequate distance between the lower row of boiler tubes and the grate line should be provided as these are important factors exerting a definite influence where high rates of combus-



General View of a Modern Anthracite Power Plant

tion are to be attained. The boiler should be so baffled that the gases may impinge upon practically the entire heating surface, yet still give sufficient stack temperature to maintain the draft. The stack dampers should be so controlled as to maintain as high a gas velocity as is consistent with the production of a minimum negative pressure in the firebox.

Some Attainable Results



With proper construction the temperature of the furnace should reach 2500 deg. F., and the products of combustion should leave the third pass and enter the breaching at a temperature not exceeding 550 deg. F. If these conditions exist, the boiler has done its full duty in heat absorption.

A. A Neat Modern Firing Alley. B. Piping above Boilers Shown in A. C. Firing Alley in Usual Type of Boiler Plant

In order to secure a proper gas velocity, it is imperative to have a suitable diameter and height of stack to give sufficient draft to overcome the resistance of the boiler when passing the maximum amount of the products of combustion and maintain a slight negative pressure in the firebox. Since forced draft is employed, the ashpit pressure is, of course, positive, and varies anywhere from one to three inches of water, depending on the thickness of the fire and the resistance of the grates.

The coal used will probably contain between 18 and 30 per cent. of ash; while the heat content in the combustible will range between 10,000 and 12,000 B.t.u. per pound. It is sometimes preferable to employ a late type of two-stage steam blower to furnish draft, since the

A Modern Reinforced-Concrete Boiler Plant

moisture of the steam passing up through the grates will prevent clinkering. This service represents about 4 per cent. of the evaporation of the boiler. Where sufficient exhaust steam is available and can be injected directly under the grate, an air blast is without question preferable, as this seldom requires over 2 per cent. of the evaporation.

But with all of their refinements, such boilers as have been described above, are not in themselves sufficient to give best results. It is first of all essential that boilers should be properly housed in a building giving abundant light and provided with ventilators for the escape of foul air and gas. The latter should be so arranged that in cold weather the boilers are so protected from drafts that there is no danger of the fittings freezing. Doors and windows should also be so arranged as to prevent currents of air sweeping from one end of the boiler room to the other and endangering the health of the attendants. A good boiler room is comfortable in the severest weather, the temperatures never falling below 60 deg. F.

Justifiable Auxiliaries

With such boilers and plants we are justified in installing such auxiliaries as soot blowers for the boiler tubes; regulating-valve control for the boiler feed water; draft-gage control for the stack and firebox, which indicates the air pressure and the condition of the fire, and whether the boiler is operating under or over its rating; steam-recording gages, which show the amount of steam produced; a temperature-recording gage in connection with the feed-water heater; and a gage showing the total amount of water used by the plant. Where much blowing off of boilers is required, a V-type recording gage is necessary.

With a coal-consumption recording device installed in the funnel leading to the receiving table of each boiler, a positive check is at hand on the firemen, and each man may be thus required to perform his true share of the work. The quantity of coal supplied to and consumed in the firebox must be uniform throughout, and the firemen, after being instructed by a qualified expert, may be placed in charge of the water tender, whose duty is to see that they do their *pro rata* work while he controls the feed water.

With this arrangement and organization any request for a greater quantity of steam or any complaint of whatever kind or source upon the boiler house should be taken up direct with the water tender, without interference of any kind or in any manner with the individual firemen.

It should be unnecessary, except as a passing remark, to state that all steam, exhaust and feed-water pipes, as well as exposed headers, should be properly insulated.

Besides providing connecting pipes suitably proportioned for the amount of steam carried, the safeguarding of workmen in and about the boilers, has become voluntary on the part of all coal companies. Such precautionary apparatus covering all suggested dangers is a necessary part of any new installation.

Non-return valves on the boiler nozzles with gate valves in the pipes connecting them to the main header, automatic closing valves on the water columns, safety fire doors, extra valves on the boiler blowoff, guards over dangerous moving parts of auxiliary machines and illuminated danger signs to be employed when repair work becomes necesary, have all become a part of modern equipment. Furthermore, for night operation abundant lighting should be furnished for reading gages, and for necessary movement about the building.

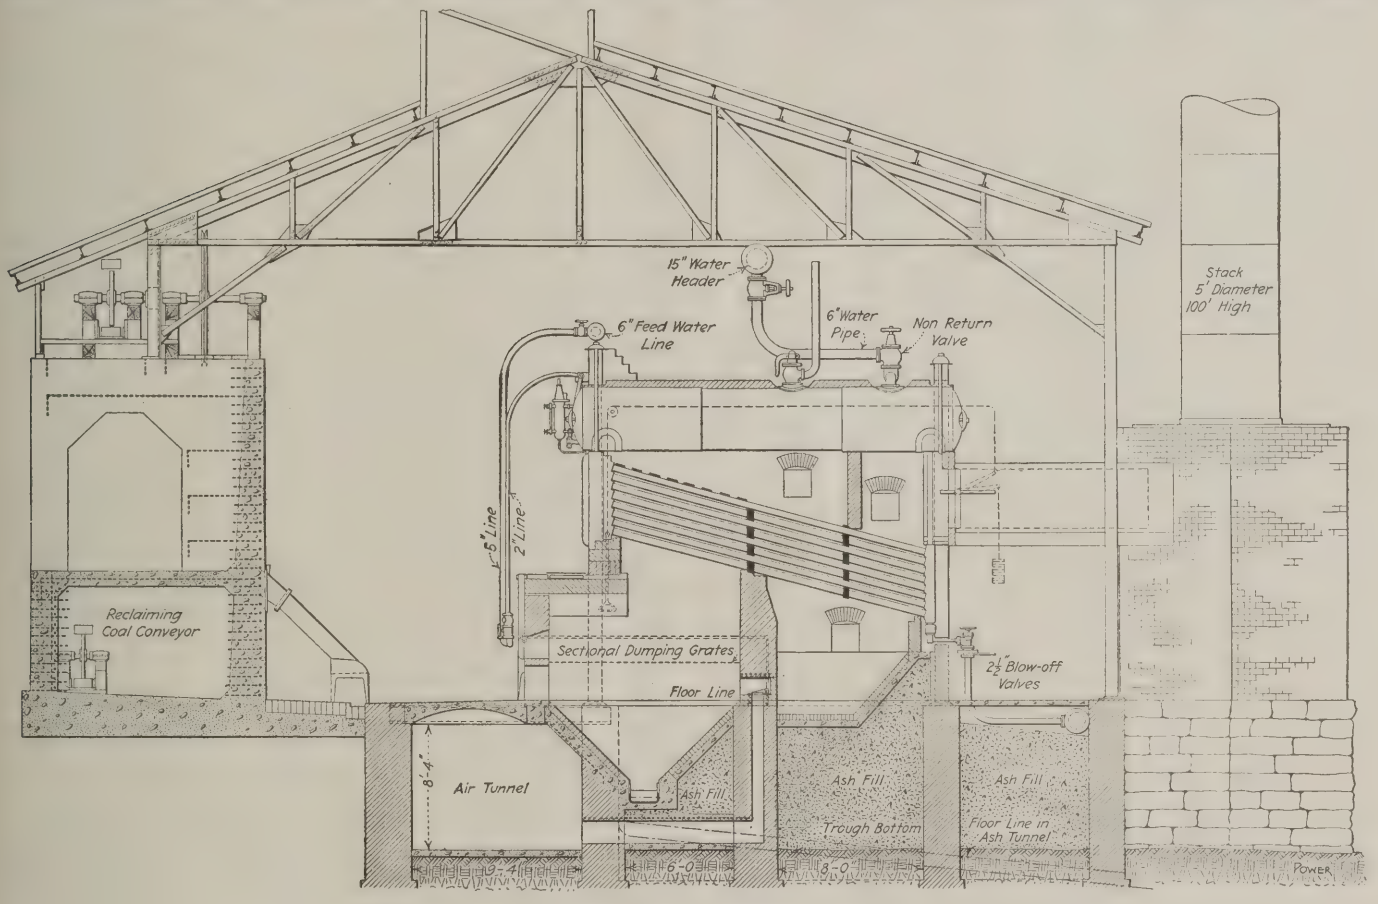
Sanitary wash rooms, drinking fountains and restful seats provided with backs may also well be provided. These latter may appear as an unimportant luxurious comfort, but observation of their effect by comparative timing in the cleaning of fires shows a saving due to their use of from 33 per cent. to 50 per cent.

A Permanent Log Should Be Kept

The employment of recording and measuring instruments is valueless unless the charts secured are properly worked up and placed in a log or static form, so that the superintendent or engineer in charge of the equipment may readily observe whenever there is a failure to maintain the standard established in any department. While this data is primarily valuable to those in direct responsibility for economic operation, it is of natural interest to those who actually handle the fuel and water. It is well,

therefore, to tabulate in simple form the weekly log, made up of the names of the firemen on the various shifts, together with that of the foreman and the actual quantity and size of fuel used, the steam generated or boiler horsepower developed, also the weather conditions and whether the figures were secured on an idle or working day.

After a standard for boiler efficiency has been established if the firemen develop skillfulness in exceeding this basis of work an approved sliding-scale bonus will automatically establish the best and most skillful men and make employment in the boiler house a competitive and desirable occupation. Such an arrangement should not conflict with the standard wage paid for general service in or about the colliery. Such standard wage, however, would become the minimum compensation and the basis upon which the bonus scale should be established.



Such improvements as have been above described would render it possible to operate a boiler continuously at 150 per cent. of its normal rating, while under emergency it might be crowded to 200 per cent. of its rated capacity. The number of boilers necessary for any installation will, therefore, be reduced to a minimum.

A still further refinement in steam consumption is that of superheating the steam to approximately 100 deg., delivering it at that temperature to the various steam users. Such a superheat has no particular bad effect upon the working parts of the various machines and effects a decided saving in the actual amount of steam consumed.

Advantageous though it may be to compound the cylinders of pumps, compressors, and the like, substitute Corliss or four-valve gear for the ordinary D-slide valve on simple engines and operate a plant condensing, as well as cover the steam lines leading to the various machines, the boiler house is in reality the first place wherein to inaugurate improvements, as there the fixed charges and the wastes are constant and consequently heavy.

Costs and Returns of Remodeling

The question to be solved, therefore, resolves itself into two parts, What will the necessary equipment cost, and what will be the saving? A new plant complete with a steel-frame building with reinforced-concrete or brick sides, fireproof roof, boilers, stacks, ash pits, forced draft, blowers, ash-conveyor lines and hoppers, steam headers, feed-water lines, steam soot blowers, concrete coal bunker, coal conveyors, turbine centrifugal or compound boiler-feed pump, feed-water heaters, recording instruments, gages, a complete equipment including every expense except the value of the land occupied by the plant and the tracks approaching it, will cost about $28 per boiler-horsepower.

Cross-Section through a Modern Boiler Plant

The type of boiler-feed pump to be used is worthy of careful consideration, as this is an important part of the steam-generating unit. A compound steam or a turbine-driven centrifugal pump of the number of stages most suitable for the steam pressure carried, is the most efficient.

Another important consideration is the location of the feed-water heater. This may be in the boiler plant or at some point in close proximity thereto, where the greatest number of exhaust-steam feeders is available. In the latter case the small feed-water line from the heater and pump to the boilers is much less expensive than a large exhaust line with its high insulation cost. This, however, is a consideration which may be readily determined in the layout of a plant.

With efficient and uptodate equipment, a boiler-horsepower-hour may be developed on about 4.36 lb. of dry coal, 8 lb. of water being evaporated per pound of coal from and at 212 deg. F. Assuming a value for the fuel of 50c. per ton, this corresponds to a coal cost of $1.09 for 1000 hp.-hr.; while the other expenses of the plant may be calculated as follows:

	Per 1000 Boiler Hp.-Hr.
Fireman, @ $6.18 per 24-hr. day	$0.29
Water tender, @ $6.24 per 24-hr. day	0.03
Ash removal, @ $1.51 per 9-hr. day	0.02
Maintenance of plant	0.008
Fire insurance, eliminated. Building fireproof.	
Safety boiler insurance	0.013
Total operating and maintenance cost	$1.451

With the old type of equipment, 7½ lb. of dry coal are necessary to develop 1 hp.-hr. Taking this coal as being worth 80c. per ton, this is equivalent to $3 per 1000 hp.-hr., while the other expenses as before are:

	Per 1000 Boiler Hp.-Hr.
Fireman, @ $6.18 per 24-hr. day	$0.60
Water tender, @ $6.24 per 24-hr. day	0.06
Ash handling, labor, @ $5.46 per 24-hr. day	0.10
Maintenance of plant	0.007
Fire insurance of plant	0.003
Safety boiler insurance	0.015
Total operating and maintenance cost	$3.785

As may be seen from the above, the saving which may be effected by the installation of modern apparatus is equivalent to $2.33 per thousand horsepower-hours, or 62 per cent. of the original cost for power. This may be properly credited against the amortization of the new equipment, and forms a basis upon which the advisability of remodeling a boiler plant may be readily determined.

It is further suggested that all of this class of work should be contracted for through competitive bids. This is because a mining organization should rightfully concentrate its efforts on the economic production and preparation of coal, and do as little work outside of this department as is consistent with reason.

An Extraordinary Experience

The following is an account of an experience that I recently had with gas, at a new opening along the Montour R.R., Washington County, Penn. Some who read this will undoubtedly recommend me for membership in the "Ananias Club"; but, nevertheless, the facts stated are absolutely true.

A few days ago, a fall occurred in one of two entries that were being driven for ventilating purposes. Three or four cars of roof slate and coal fell suddenly, near the face of one of these entries. A short time before, the roof was apparently sound. As the cavity filled with gas, I had a canvas brattice run from the last breakthrough to the fall, and the face was practically clear before the last nail was driven. A current of about 6000 cu.ft. per min. was passing the place.

A little later, not being able to detect gas with the safety lamp, I raised an open light into the cavity above the fall to inspect the condition of the hanging rock. About 6 in. from the top of the cavity, the light was suddenly drawn upward and the lamp extinguished. Wondering at this, I relit the lamp and tried again, raising it more slowly. At about the same distance from the top, as before, I noticed a blue flame appear around and above the flame of the lamp. Holding the lamp still in this position, I observed as pretty a cap as was ever formed in a safety lamp. This cap was from 4 to 4½ in. in length, about 1 in. in diameter at the base and tapered to a point. After observing the cap for about 30 sec., I slowly raised the lamp higher and the flame was extinguished. Continuing the experiment, I repeatedly got a cap on the open flame, which was extinguished on raising the lamp higher, as before.

On one occasion, the cap was detached from the lamp and drawn up against the roof where it revolved like a top, moving around a space from 5 to 10 ft. in diameter. This continued for about ½ min., when suddenly a burst of flame rolled up to the face, down both ribs and back both sides of the canvas. This left the impression that there was gas below and all around. The flame was not a compact body, but descended from the roof in folds or waves, making an interesting sight.

Two days later, I repeated the experiment, and obtained the same results as before, in the presence of the superintendent and two firebosses, who exclaimed, "Pretty!" "Beautiful!" During the last four days, I have repeated the experiment several times with the same results. In making these tests, immediately after the gas would burn itself out bursting into a flame as described, I would raise an open light and get a cap 1 ft. from the top, but the flame would be extinguished on raising the lamp higher. In some of these attempts, it would be difficult to light the gas, except where it issued from the fissures of the slate; but, after repeating the experiment two or more times, the gas ignited more readily.

I should state that the top of this cavity is about 3½ ft. above the "lip" or drawslate. The slate fell to a white "bastard" slate, having a smooth surface. The gas is given off quite freely through a fissure in the slate 9 in. in length and some fissures on the sides; but the pressure is not sufficient for the gas to be heard as it escapes from the strata. The color of the burning gas is a dark red or purple.

I have tried to describe the observed phenomena as nearly correctly as possible, relating the incidents as they have occurred with little variation during the last four days. I will not attempt to offer any opinion myself, but would be glad to have the readers of COAL AGE suggest a possible cause for the strange behavior of the gas. After an experience of six years as fireboss, assistant mine foreman and mine foreman, in mines of three different counties in the Pittsburgh district, all of which generated more or less gas, this is the most extraordinary occurrence I have witnessed.

I may add that, to test the gas further, I cut off the air from the place and allowed over a foot of gas to collect, when it acted the same as ordinary explosive gas. When doing this, however, I used only a safety lamp.

JOHN LAWLOR, JR.,
Mine Foreman.

Lawrence, Penn.

[The above narration must be taken for what it is worth. Allowing its credibility, it portrays an almost inconceivable exhibition of reckless daring on the part of those who observed the alleged experiments. While we would not question the veracity of our correspondent, we are compelled to suggest that the repetition of such experiments is to court danger and possible death, not only for one's self, but for all in the mine at that time. We hope to hear further comments from readers.—EDITOR.]

The Kentucky Compensation Act

SYNOPSIS—A review of the salient features of the Workmen's Compensation Act, recently passed by the Kentucky Legislature, with particular reference to its bearing on the coal operations of the state.

The recent passage by the Kentucky legislature of the Workmen's Compensation Act will affect scores of large and small coal operations in both the eastern and western sections of Kentucky. The passage of this act is due largely to the strong coalition formed in support of it by the coal miners and coal operators of the state.

Originally, there were four bills on this subject before the legislature, COAL AGE, Vol. 5, p. 362. The similarity between these several bills, however, led, eventually, to the substitution of the original labor bill (the Meyers-Knight bill), and it was this which became a law.

Supporting the bill, as finally adopted, were such organizations as the Kentucky Mine Owners' Association, the Southern Appalachian Coal Operators' Association, and the Western Kentucky Coal Operators' Association. The Kentucky Mine Owners' Association was most active in its efforts to secure compensation legislation, and during the entire session, maintained headquarters at Frankfort, the capital, where President Hywell Davies and Secretary W. H. Cunningham were in active charge.

The principal features of the compensation act are: State insurance, with options to permit the employer to carry his own insurance, or to secure liability insurance; administration by a board composed of existing state officials, with the minimum of expense; penalty by additional premiums where willful injury is inflicted, or is received, where the employer is violating the law; semiannual readjustment of rates, based on experience of the preceding six months.

The Workmen's Compensation Board

The attorney-general, the commissioner of insurance and the commissioner of agriculture, labor and statistics of the state are to constitute the Workmen's Compensation Board under this act, which will take effect Jan. 1, 1915. Each is to receive in this capacity a salary of $75 per month payable out of the compensation funds.

The board is given all necessary authority to administer the act, such as that to make investigations, swear and examine witnesses, punish for contempt (through the courts), and so forth. It is authorized to collect from employers detailed information regarding their business, insofar as it is pertinent for the purposes of the act, but it is provided that this information shall be regarded as confidential, and that any person connected with the board divulging any such information, except in authorized statistical form, shall be fined not less than $100 nor more than $500.

All employers of six or more persons, in any of the 22 classes created by the act, as these may be rearranged or modified by the board, and all who may, with their employees, voluntarily make application for that purpose, are made subject to the provisions of the act. And "coal mines, including their tipples, power, light, heating and ventilating plants, tramways, private tracks and sidings, and accessory and auxiliary plants, working in or with byproducts," comprise the first class.

Rates for the purpose of accumulating a compensation fund, not exceeding a maximum charge of $1.25 on each one hundred dollars of the gross annual payroll of each employer, are to be fixed by the board, subject to the semiannual readjustment referred to; and in order to enable the board to proceed to fix its rates, as provided by the act, they are required to furnish all information desired, under penalty of a fine of $500, to be collected by civil action. Premiums are payable monthly, but those for the first three months are to be paid on or before Jan. 1, 1915, in order to give a substantial fund to start with.

The usual provision, that the continuance in the employment shall be conclusively presumed, as against any employee, to constitute a contract with the employer to accept the compensation provided by this act, in case of injury, and to waive all right of action for such injury, where the employer has given notice of his intention to accept the provisions of the act, is included; but, it is also provided that where an employee elects, and so informs his employer, not to accept the provisions of the act as to compensation, the common-law defenses of contributory negligence, assumption of risk, and the act of a fellow-servant are to be available against him, with such others as may exist.

On the other hand, it is provided that where an employer elects not to accept the provisions of the act with reference to compensations, he shall be deprived of the common-law defenses. He is also specially penalized in cases where injuries are due to his willful act, to the failure to perform a statutory, or other nondelegable duty, or where a minor employee, illegally employed, is injured. In certain of these cases a right of election is given to the employee between his right of action and the compensation provided by the act.

Injuries received by employees while intoxicated, or by their deliberate, self-inflicted act, or by willful misconduct, are barred.

Compensation Obtainable

The act provides for a maximum compensation of $3750 in case of death or permanent disability, and of one-half of the weekly wages, with a maximum of $12 a week, for injury resulting in temporary total disability. For temporary disability the compensation is one-half of the loss of income caused by the disability, with a maximum of $12 a week. The minimum weekly indemnity is $5, except where the weekly wage is less than that sum, when the compensation equals the wage.

Hospital and medical attendance, to the extent of $100, are to be paid out of the fund, and funeral expenses up to $75, in addition to other compensation; and in case of death, where there are no dependents, these items are all the payments to be made out of the compensation fund. Dependents are defined as the wife, living with the deceased at the time of his death, and children under the age of sixteen, living with the parent. In other cases the board decides the matter as a question of fact, with the limitations that no person shall be considered a dependent except husband or wife, brother or sister, ancestor or lineal descendant.

Upon satisfactory proof of solvency and ability to pay

the compensation provided by the act, any employer may administer the compensation himself; and he may, in such case, carry liability insurance, "provided the amounts to be paid are not less than that provided in this act"—a proviso which would seem to be of but little benefit to the liability-insurance companies, in view of the fact that the usual policy limits their liability in any one accident to $10,000, and that their rates, for coal mines, at least, are much above the maximum rate provided for in the act.

All employers subject to the act must notify the board on or before Nov. 1, 1914, of their election not to accept the provisions of the act.

There are appropriate provisions covering adjustment of controversies, appeals, employers in interstate business, and so forth, but those outlined above are the salient features of the act. The coal interests of the state, operators and miners alike, are willing, as far as is now apparent, to accept it and act under it, leaving such defects as may appear to be remedied by future legislation.

A Method of Measuring Goaf Temperatures*

By T. F. Winmill

SYNOPSIS—A description of the construction and application of a new instrument for measuring goaf temperatures, together with certain tests relating thereto. The device exhibits increased electrical resistance on any rise in temperature.

It is important to know, in connection with the question of gob fires in mines, what is the normal goaf temperature. If the goaf be absolutely air-tight, its temperature should ultimately become that of the undisturbed strata surrounding it. A small air-leak will, however, cause oxidation of the coal left in the goaf and a corresponding rise in temperature.

An apparatus has been devised which will allow of a continuous measurement of the goaf temperature in any place, without the necessity for boreholes. As is well known, the electrical resistance of a metal varies considerably with the temperature, and this property is made use of in constructing resistance thermometers. These instruments are very commonly used for accurate temperature measurements, and a simple modification suitable for use in mines is herewith described.

Description of the Apparatus

A strip of sheet-mica 1 cm. broad and about 1 mm. thick is bound with two copper collars, made from strips of copper-foil. Both ends of a coil of nickel wire, ⅛ mm. in diameter, are soldered to the copper collars. For convenience in standardizing and subsequent use, the coil is made of such length as will give a resistance of 25 ohms at 0 deg. C. Two copper leads of No. 14 gage cotton-insulated wire are then soldered, one to each copper collar, in the position shown. The coil is now wrapped in very thin asbestos paper in order to insulate it, and slipped into a copper tube, the ends of which are then sealed with any of the usual silicate cements. Long leads must then be fixed to the projecting copper wires at *a* and *b* so that the coil may be well buried in the goaf. These wires are made most conveniently of three No. 22 gage copper twisted together and well insulated. Two leads are fastened to one of the coil-terminals and one lead to the other.

In measuring the resistance from the end of the leads *B* and *C*, the resistance of the coil plus the resistance of the leads is obtained; but in measuring the resistance between *A* and *B*, the resistance of the leads only is arrived at. Since all the leads are exactly similar, the difference between these two measurements gives the resistance of the coil independently of that of the leads. By this means leads any length desired may be employed. Certainly leads a mile long would offer no difficulties to accurate measurement of the resistance of the coil.

How the Apparatus Is Used

The apparatus is used as follows: The copper tube is placed in a strong iron tube of about the same length, and then put in the desired position in the open goaf. As the face advances and the goaf closes, the leads are carried forward along the floor, being covered with about 6 in. of sand, so as to prevent them from being cut as the weight comes on. The coil is then permanently in position and by measuring the resistance at any time the goaf temperature at that point is obtained. Under most favorable conditions the measurements are correct to about $\frac{1}{10}$ deg. F., more generally the accuracy is about ½ deg. F.

Instrument for the Measuring of Goaf Temperatures

The temperature-coefficient of the nickel wire described has been determined from measurements at 0 deg., 25 deg., 60.30 deg., 80.48 deg., 100 deg., 132 deg. and 184 deg. C., and from these results the following relation is deduced:

$$R = A + BT + CT^2$$

Where R = the resistance of the coil in ohms; A, B and C are constants, and T = the temperature of the coil in degrees Centigrade.

For a coil resistance of 25 ohms at 0 deg. C.,

$$A = 25$$
$$B = 1.128 \times 10^{-1} \text{ and}$$
$$C = 1.746 \times 10^{-4}$$

For a coil of resistance A at 0 deg. C., the above constants must be multiplied by $A/25$.

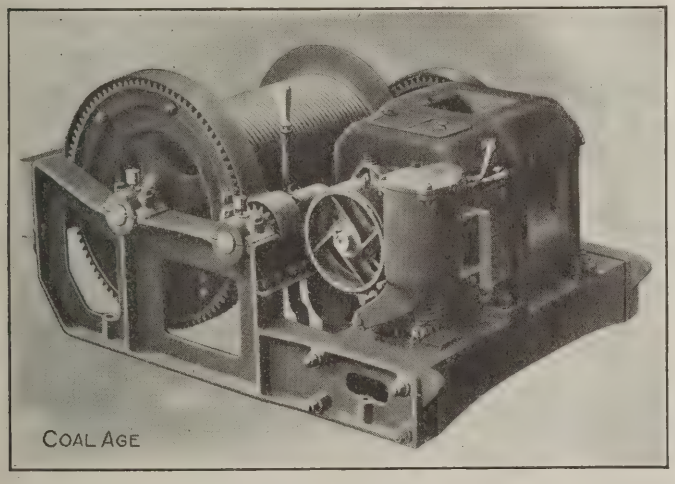
Results of Tests

The apparatus was tested at a rib-side which was being left to divide off a district and the results of the tests are given in the appended table. The coil is now buried at a point about 50 yd. from the edge of the goaf.

*From a paper presented at the 24th annual meeting of the Institution of Mining Engineers, Sept. 24, 1913.

RESULTS OF TESTS WITH THE APPARATUS

Date	Measured Resistance in Ohms Coil and Leads	Leads	Coil	Temperature, in Degrees Fahrenheit
Nov. 29, 1912	27.93	0.61	27.32	68
Dec. 13, 1912	27.91	0.61	27.30	67.8
Jan. 2, 1913	28.84	0.61	28.23	81.15
Jan. 3, 1913	30.41	2.21	28.28	*82.2
Jan. 10, 1913	30.21	2.10	28.11	80
Jan. 17, 1913	30.10	2.09	28.01	79
Jan. 31, 1913	29.91	2.10	27.81	76
Feb. 11, 1913	30.07	2.10	27.97	78
Feb. 17, 1913	30.60	2.12	28.48	85
Feb. 24, 1913	28.85	0.45	28.40	†84
Mar. 7, 1913	28.86	0.45	28.41	84
April 7, 1913	30.64	2.23	28.41	*84



* Leads lengthened. † Leads cut by a car.

The low initial temperatures are due to the fact that the rib-side on being left had been well stowed with wet sand. After this sand had dried, the temperature rose to that of the strata, showing that the stowing has been tight and that no air is leaking in.

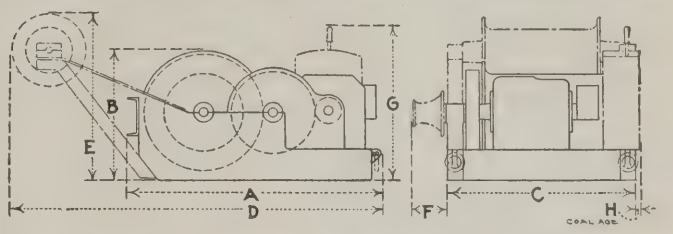
A Small Portable Electric Hoist

With the increased use of electricity around mining plants, the operators will welcome the appearance of a small portable electric hoist as shown herewith. This particular machine was designed essentially as a drag for spotting railroad cars on adverse grades, but the possibilities of such a portable and flexible apparatus around a mine are too numerous to mention.

The frame consists of heavy cast-steel sides securely connected by cast- and structural-steel cross pieces, forming a rigid unit. The frame bottom is made flush for skidding and provided with bosses for holding down bolts. Lugs are also provided for attachment to hauling links for moving the machine to different locations.

THE SHAW PORTABLE ELECTRIC DRAG

The winding drum is of cast iron, machined with grooves to keep the hauling cable in place. The cable is of special plow-steel rope, ¾ in. in diameter, 10 wires to the strand, six strands and a hemp core.



STANDARD RATINGS AND DIMENSIONS OF ELECTRIC HOISTS

Size	Rope Pull, in Lb.	Rope Speed Ft. P. M.	Dimensions A	B	C	D	E	F	G	H
5	2300	60	5 Ft. 5 In.	2 Ft. 10 In.	4 Ft. 2 In.	7 Ft. 10 In.	3 Ft. 6 In.	10 In.	3 Ft. 5 In.	
8	2700	85	5 Ft. 5 In.	2 Ft. 10 In.	4 Ft. 2 In.	7 Ft. 10 In.	3 Ft. 6 In.	10 In.	3 Ft. 5 In.	
12	3200	110	5 Ft. 5 In.	2 Ft. 10 In.	4 Ft. 2 In.	7 Ft. 10 In.	3 Ft. 6 In.	10 In.	3 Ft. 5 In.	5 In.
18	4000	130	5 Ft. 5 In.	2 Ft. 10 In.	4 Ft. 2 In.	7 Ft. 10 In.	3 Ft. 6 In.	10 In.	4 Ft. 7 In.	8 In.
25	5000	150	5 Ft. 5 In.	2 Ft. 10 In.	4 Ft. 2 In.	7 Ft. 10 In.	3 Ft. 6 In.	10 In.	4 Ft. 7 In.	11 In.

All shafts are carried in capped bearings with bronze bushings. The gears are of steel with cut teeth. All gears are guarded. The drum pinion is free on the shaft and a jaw clutch is provided thereon for coupling same to shaft. The drum is, therefore, free to rotate when necessary to unwind the rope by pulling on it. The clutch may be left in engagement and motor controlled at proper speed to unwind rope as the end is carried away.

The motor is rated on a basis of 40° C. temperature rise after 30-min. run with full load. It is designed exclusively for crane and hoist service.

The machine is regularly built as shown in full lines on diagram, or with either one or both auxiliaries, as shown in broken lines, i.e., guide drum or niggerhead. The accompanying table is for drags of standard specification, but machine can be altered to meet special requirements.

SKETCH SHOWING PRINCIPAL DIMENSIONS

The apparatus is designed so that it can be used as a portable electric winch, or as a stationary electric hoist. For the latter class of service the hoist would be arranged for dynamic lowering and the controller can be located independently of the hoist proper which often works out as a substantial advantage.

These machines are built by the Shaw Electric Crane Co., of Muskegon, Mich., and sold by Manning, Maxwell & Moore, Inc., New York City.

Recent Legal Decisions

Proving Unlawful Sale of Underweight of Coal—In a prosecution against a retail coal dealer on a charge of willfully selling coal at an underweight, the state was entitled to prove underweights in other sales made by him for the purpose of negativing a claim of mistake in the particular instance. (New Jersey Supreme Court, State vs. Mor, 89 Atlantic Reporter 755.)

Amount Recoverable for Injury to Miner—Where a coal miner established a right to recover against the company which employed him, on account of injury sustained by him in being overcome by black damp, a verdict for $300 in his favor was not excessive, though it appeared that he was not so seriously injured as to require medical attention. (Kentucky Court of Appeals, Mt. Morgan Coal Co. vs. Shumate, 163 Southwestern Reporter 1099.)

Danger Not Assumed by Miner—A coal miner does not assume the risk of being injured on account of noncompliance on the part of his employer with a statute requiring a certain space to be provided in entries sufficient to permit drivers of cars to keep clear of the same. (Pennsylvania Supreme Court, Smith vs. Stoner, 89 Atlantic Reporter 795.)

Extent of Mine Foreman's Control—Under the Pennsylvania Mine Foreman Law, a mine operator is not liable for injury to a person while in the mine to seek employment, even though such injury be due to negligence of a miner in failing to give warning of the approach of a car; this is a matter within the control of the mine foreman employed under the law. (New York Supreme Court, Appellate Division; Bigus vs. Lehigh & Wilkes-Barre Coal Co., 146 New York Supplement 107.)

Accident Frequency among English-Speaking Men and Others

By Howard I. Smith*

SYNOPSIS—Only in West Virginia are statistics on this subject available. The Germans appear to have the highest nonfatal-accident rate and greatest proportion of accidents from falls of coal, drawslate and roof and to rank second in general fatal accident frequency. But the number of Germans employed makes the value of the result uncertain. It seems established that the Italians and negroes take less care of themselves than the American whites. While the English-speaking foreigners are too few to furnish reliable evidence, the statistics do not give them a leading place as careful miners.

The frequency of accidents among those foreigners who come from other countries than those where English and German are spoken has been repeatedly discussed, but most of the men who expressed themselves have given merely personal observations and beliefs. These, while interesting, are not convincing and facts are needed.

Statistics on this question are sadly lacking because only one state, West Virginia, has gathered sufficient figures to permit the conclusions to be drawn. A few states do clasify the fatalities by nationalities, but fail to give the number of men employed from any given nation. However, on account of the compensation acts which are being considered and other important questions, the statistics bearing on this subject, no doubt, may, in the future, be more fully compiled and become available for use in attempting to improve the accident rates.

In Ohio and Pennsylvania, the number of men killed of the various nationalities have been tabulated, but not the numbers employed so we cannot draw sufficient evidence from which to establish just what nationalities are the most unfortunate.

As many of the foreign miners get their first experience in mining in this country, the following table drawn from the Chief Mine Inspector's Report of West Virginia for 1911, is of great interest:

TABLE I. LENGTH OF EXPERIENCE OF PERSONS KILLED AND INJURED AT THE WEST VIRGINIA MINES 1901 TO 1911, INCLUSIVE

	Per Cent.
Under 3 months	10.71
Over 3 months including 6 months	5.62
Over 6 months including one year	13.44
Total including one year	29.77
Over 1 year including 5 years	38.17
Over 5 years including 10 years	17.94
Over 10 years	14.12
Total	100.00
Number of men reported from which these deductions are made	6638

From the published report unfortunately there is no way of determining what proportions given in the above table of those killed in the several groups are foreigners or do not speak English. This table, if it represents the average conditions in the various coal fields, indicates that when the men first entered the mines they were ignorant of danger for the first period of three months, then they became very cautious during the second three-months period, at the end of which time they again become indifferent to dangers and accidents followed. The continued decrease in the number of accidents after the first five years is probably due to the smaller number of men employed having the stated length of experience.

The following tables, Nos. 2 and 3, taken from the mine-inspectors' reports of Ohio and Pennsylvania, show only the relative number of men of different nationalities killed in and about the mines, and so we are prevented from drawing conclusions from them. These tables are, however, interesting.

TABLE 2.—TOTAL FATAL ACCIDENTS IN AND ABOUT THE MINES OF OHIO ARRANGED ACCORDING TO NATIONALITY ABSTRACTED FROM THE ANNUAL REPORT OF THE INSPECTOR OF MINES—1911

	No.	Per Cent. of Total		No.	Per Cent. of Total
American	49	45.0	Hungarian	5	4.6
Polish	15	13.7	Austrian	4	3.7
Slavish	12	11.0	Greek	3	2.7
Italian	8	7.3	Other nationalities	13	12.0
Total				109	100.0

Thus 49 Americans were killed and 60 foreigners and the death rate of Americans was 45 per cent. of the total whereas the rate of foreigners was 55 per cent.

TABLE 3. PERCENTAGE OF MEN, BY NATIONALITIES, KILLED IN AND ABOUT THE MINES OF PENNSYLVANIA FROM 1899 TO 1911, INCLUSIVE

	Per Cent.		Per Cent.
Americans	18.42	Germans	3.32
Slavonians	18.29	English	3.31
Italians	13.32	Irish	1.70
Polish	11.60	Magyar	1.55
Hungarians	9.75	Scotch	1.54
Austrians	7.59	Lithuanian	1.47
Russians	3.45	Other nationalities	4.69
Total			100.00

From page LXXXVI, Report of the Department of Mines of Pennsylvania, Bituminous—1911.

We are fortunate in finding in the mine-inspector's report of West Virginia, not only the number of fatal accidents of the different nationalities, but we have the number of men employed in and about the mines for each nationality for the years 1907 to 1911, inclusive, and from this we can figure the death by accident rate for each. These are shown in Fig. 1 and are based on a total of 317,661 man-years and 1997 deaths.

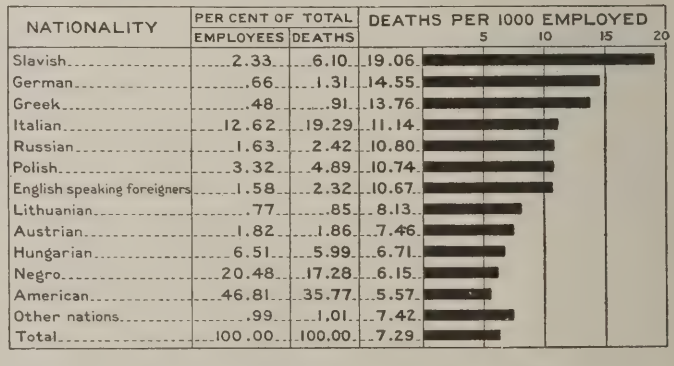


FIG. 1. FATAL ACCIDENTS IN AND ABOUT MINES IN WEST VIRGINIA, 1907-1911

In the above, the nationalities of 14.27 per cent. of the employees were unknown and those of 0.60 per cent. of the men killed were also unknown. The tables were computed by discarding the unknown in each case and figuring the death rate on the number of each reported, which

*Mining engineer, Bureau of Mines, Pittsburgh, Penn. An answer to a query in the question box of the Coal Mining Institute of America read Dec. 5 at the Pittsburgh meeting.

is higher than it should be, but the proportions will, no doubt, remain the same.

The table of nonfatal accidents is shown in Fig. 2, which is based on 317,661 man-years and 4083 nonfatal accidents. The nationalities of 14.23 per cent. of the total number of men employed were unknown and those of 0.36 per cent. of the nationalities of those sustaining accidents were also unknown. As in the previous table, the accident rate shown will be higher than it should be, but the proportions will, no doubt, follow the same order, as if they were correct.

Fig. 3 represents the death rate of the men employed

NATIONALITY	PER CENT OF TOTAL		ACCIDENTS PER 1000 EMPLOYED (5 10 15 20 25 30)
	EMPLOYEES	NON-FATAL ACCIDENTS	
German	.66	1.16	26.30
Slavish	2.33	3.89	24.88
Russian	1.63	2.36	21.60
English speaking foreigners	1.58	2.12	19.94
Polish	3.32	4.21	18.94
Lithuanian	.77	.91	17.70
Italian	12.62	14.88	17.57
Negro	20.48	19.63	14.29
Hungarian	6.51	5.91	13.54
American	46.81	41.31	13.16
Austrian	1.82	1.58	12.90
Greek	.48	.39	12.23
Other nations	.99	1.65	24.84
Total	100.00	100.00	14.91

FIG. 2. NONFATAL ACCIDENTS IN AND ABOUT MINES OF WEST VIRGINIA, 1907-1911

in the mines who were killed by falls of coal, slate or roof, and is based on 256,058 men employed for one year and 836 deaths; the nationalities of 14.91 per cent. of the employees were unknown and those of 0.48 per cent. of the dead were also not known.

These three tables clearly indicate which nationalities in West Virginia should most need education in safety methods, but it would not be safe to assume that the same ratios of accidents to nationalities will be found in other states.

Why the death rate is higher among men of one nationality than among those of another is hard to explain. We may suppose that it is because some men are more ignorant of danger, some more awkward and clumsy, some have more of a dare-devil spirit causing them to court danger. Others, perhaps, have a pride in looking out for themselves and their fellow countrymen. Possibly men of some nationalities are naturally less methodical or careful than others, or perhaps their training at home or in school may be more deficient.

NATIONALITY	PER CENT OF TOTAL		DEATHS PER 1000 EMPLOYED (1 2 3 4 5 6 7 8 9)
	EMPLOYED IN MINES	DEATHS FROM FALLS OF COAL SLATE AND ROOF	
German	.76	1.68	8.47
Greek	.43	.84	7.52
Slavish	2.78	4.21	5.78

FIG. 3. FATAL ACCIDENTS FROM FALLS OF COAL, DRAW SLATE AND ROOF IN MINES OF WEST VIRGINIA, 1907-11

In the summary report of the Immigration Commission, we find that for 88,368 employees in the mines of the eastern and central coal fields, of whom detailed information was received, 61.91 per cent. were of foreign birth and 9.5 per cent. were of native birth but with a foreign father. Only 20.7 per cent. of the foreign-born employed had had any experience in bituminous-coal mining before coming to this country. Should we deduct from this per cent. the men from Great Britain, I believe this percentage would be lowered considerably.

Longwall in Seams Liable to Spontaneous Combustion

BY J. E. SPICER*

SYNOPSIS—Working a seam at South Derbyshire, England, where the coal is liable to spontaneous combustion. Several attempts to prevent the ignition of the coal by excluding the air from the waste proved unsuccessful, until the adoption of the longwall system of mining. Seam generates gas. Description of the method employed.

The longwall workings in the main coal seam of South Derbyshire, England, are an interesting example of the application of this method to the working of coal liable to spontaneous combustion. This seam was formerly worked by the common system of longwall advancing, the roads being maintained by well built packwalls. Much trouble was experienced by the heating of the gob, which resulted in frequent fires difficult to isolate. Attempts were made to overcome this difficulty by building continuous walls of clay, which were locally known as "wax walls." These efforts, however, were only partially successful in excluding the air from the waste and preventing spontaneous ignition from taking place. The inflammable nature of this coal together with the gas generated rendered the mine subject to frequent gob fires.

The room-and-pillar system was also tried, in the working of this seam, the pillars being removed by "lifts" or "skips," in the usual manner. Several serious fires occurred, in the use of this method and, as a result, strong stoppings of brick or concrete had to be built and a portion of the mine indefinitely abandoned. The method of longwall retreating that I am about to describe proved the most successful process that has been thus far adopted, in the working of this seam. It is the method by which the seam is worked today.

*Cumberland, B. C., Canada.

The accompanying illustration (Fig. 1) shows a vertical section of the main coal seam to which I have referred. The workable portion of this seam is included between the fireclay and shale that forms the floor and the "batt" underlying what is called the "over coal." These several strata are shown in the section. The over coal, which is 5 ft. in thickness, is of inferior quality and is generally left in to form the roof in the first working. Sometimes, however, the lower coal is only taken out to the "tops," which forms a good roof and saves the handling of the "batt" just above it. The "best hards" being of splendid quality is loaded separately. The fireclay, forming the floor of the seam, is also worked, to some extent, and is used for brick-making, this industry being carried on largely in the district.

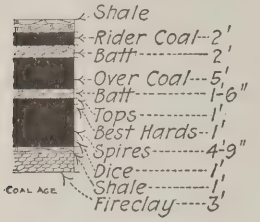

FIG. 1. VERTICAL SECTION OF COAL SEAM

While the coal itself remains fairly regular, over a large area, maintaining its average thickness and quality, the other strata vary considerably. For example, the batt underlying the over coal varies from 6 in. to 4 ft. in thickness. This feature practically decides the question of whether or not the "tops" should be taken down in the first working.

The general plan adopted in the working of the main coal seam is illustrated in Fig. 2. Parallel headings are first driven in the coal, from 9 to 12 ft. in width, and from 90 to 120 ft. apart. These headings, which serve as haulage roads, are connected by crosscuts of the same width. The crosscuts, which are driven for ventilation, should be as few in number as possible. On the plat they are shown 50 yd. apart. Owing to the thickness of the intervening pillars, the driving of the crosscuts is expensive; and, furthermore, when retreating, they are apt to cause heavy caves or roof falls.

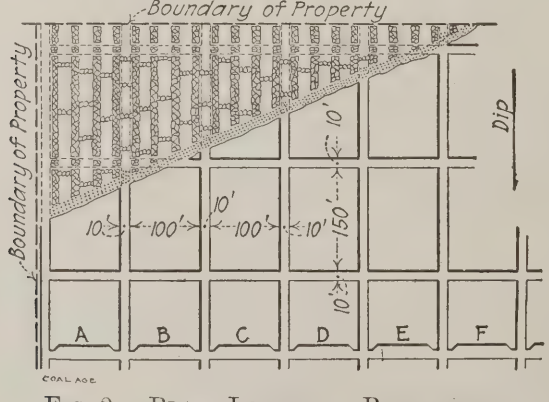

FIG. 2. PLAN, LONGWALL RETREATING

The headings are driven right to the boundary line or the extent of the property, before the longwall face is commenced. As a precaution against spontaneous combustion in the waste, all the slack and small coal are loaded out of the mine. This greatly reduces the chances of mine fires occurring in the waste.

The seam gives off a quantity of marsh gas (CH_4); but, for the most part, the gas drains from the pillars, during the first working. Drill holes are put up in the roof, at intervals, to allow the gas to drain from the overlying strata. It is necessary, in order to prevent the accumulation of gas in any portion of the mine, to maintain a strong ventilating current, which is made to sweep the working faces, the circulation being assisted by secondary fans where that is necessary. The strong air current is all the more important, because of the presence of gas and the possibility of fire starting in the waste, which presents a serious and dangerous condition.

As shown in Fig. 2, as the headings reach the boundary line, in continuous succession, the longwall face is extended. It is important to keep this longwall face in a straight line running at an angle with the heading, in order to reduce to a minimum the possibility of a cave cutting off a considerable length of the working face at one time. This would be very apt to occur, if the face were made to run square across the pillars.

During the work of retreating, as the coal is extracted, packwalls are built 9 ft. wide, with 18-ft. wastes between them, except at the headings where the waste space is narrowed to a width of 12 ft. The packs are built of coal taken from the interior portion of the seam, the interstices being well filled with sand or flue dust, which would tend to extinguish any fire that might occur in the mass. This system is continued as long as the roof holds good; but if a cave should occur in the waste, the place is built off by a packwall 6 ft. wide, which is made as tight as possible to exclude the air.

The timbering consists mainly of posts set in rows 5 ft. 6 in. apart, the posts in each row being spaced the same distance, center to center. Two rows of posts are set in each crosscut, and three rows at the longwall face, the third row at the rear being drawn and set forward as the face advances. These are not shown in the figure. The headings require to be well timbered, since they are weakened by long standing. As shown in Fig. 2, the headings are driven to the rise. As shown also in Fig. 2, at *A, B, C,* etc., the plan was adopted, at one time, of widening the crosscuts, a short distance from the heading. The crosscuts were widened to 15 or 20 ft., but the plan proved to be bad policy, as it was more expensive and caused heavy caves when reached by the retreating longwall face. These caves cut into the longwall face so badly that the plan had to be abandoned.

Coming Mine-Safety Field Meets

The United States Bureau of Mines is being continuously called upon to lend its coöperation in various field meets and contests in first-aid and mine-rescue work. The following field meets and contests have been called to the attention of the bureau within the last few days:

April 25: Ironwood, Mich. Gogebic Range Mining Association. O. E. Olsons, Sec.-Treas., Ironwood, Mich.

May 2: Harrisburg, Ill. Saline County Mine Safety Association. Oscar Cartlidge, Springfield, Ill. Chairman, Program Committee.

May 9: Lexington, Ky. Kentucky Mining Institute and Kentucky Mine Operators' Association. C. J. Norwood, Program Committee, Chairman.

May 13-15: Bluefield, W. Va. West Virginia Medical Association and Pocahontas Coal Operators' Association. Mr. Tierney, of the Powhattan Coal & Coke Co., and Mine Foreman Henson, of the United States Bureau of Mines, are planning such a meet in correspondence with Dr. A. P. Butt, of Davis, W. Va. Details not definitely settled.

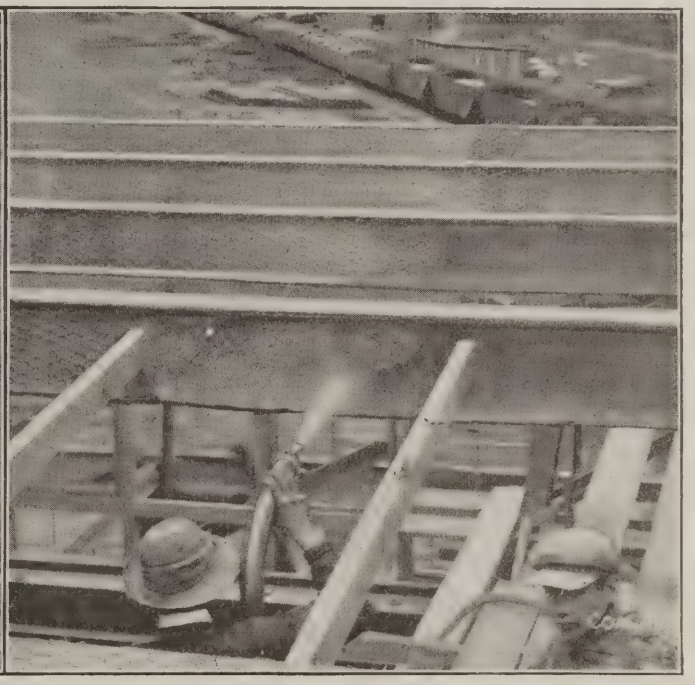
May 18: Fort Smith, Ark. W. D. Ryan and J. J. Rutledge, of the Bureau of Mines, are arranging this meet.

May 21: McAlester, Okla. W. D. Ryan and J. J. Rutledge, of the Bureau of Mines, are arranging and will probably attend.

May 25: Pittsburg, Kan.

May 28: Moberly, Mo.

June 1: Des Moines, Iowa. (This date and place in Iowa may be changed later.)



Availability of the Cement Gun for Mine Work

SYNOPSIS—The cement gun deposits cement mortar by an air blast mixing the water with the dry ingredients at the delivering nozzle. The material formed is known as gunite and is denser and stronger than ordinary cement mortar or concrete. It is well suited for making buildings fireproof and permanent, and for coating headframes, tipples and mine roadways. It could also be used with advantage for stoppings and overcasts.

The cement gun has been described before in these columns† but its availability for the specific uses of the mine owner were not indicated. It is probable that it would make slow headway in underground mining work regardless of its intrinsic value for such purposes were it not for the fact that it is a most desirable piece of equipment for outside mine uses. Once purchased by mining companies for surface work, it is likely to be rapidly introduced below ground for compressed air is frequently available and the height of a low machine 4 ft. 8 in., and its width 3 ft. 1 in. make it readily suitable to movement from place to place. When this machine, weighing only 1500 lb., is tilted, its height is the same as that of the wheels, namely 36 in. Consequently it can be taken almost anywhere.

Cement Gun Being Used to Coat Interior of Building

Gunite Being Deposited on Steel Work. Note Reinforcement

Manner of Operation

The cement gun practically consists of a cylinder for storing dry cement mortar, a feeder for delivering measured quantities to an opening which quantities are driven by air pressure through a hose line till they reach a nozzle where they are hydrated by a water hose just before they emerge into the air.

The storage chamber must necessarily consist of two parts marked *A* and *B*, the latter being kept constantly at a pressure of 45 lb. Before *A* is loaded, the air in it is allowed to escape. The small cone is lowered by lifting the handle and the dry mix falls into the cylinder *A*. The cone is then lifted and air under pressure is admitted. The inverted cone *C* becomes tightly seated and as the pressures in *A* and *B* become equal the inverted cone *D* can be lowered permitting the charge to fall into cylinder *B*. On raising the cone *D* by the handle, a cycle of operations is completed and the upper cylinder is ready for depleting of air and recharging with a new batch of mix. In this way continuity of operation is insured with only one machine feeding the nozzle, the work not being stopped during the charging of the hopper.

How the Charge Is Hydrated

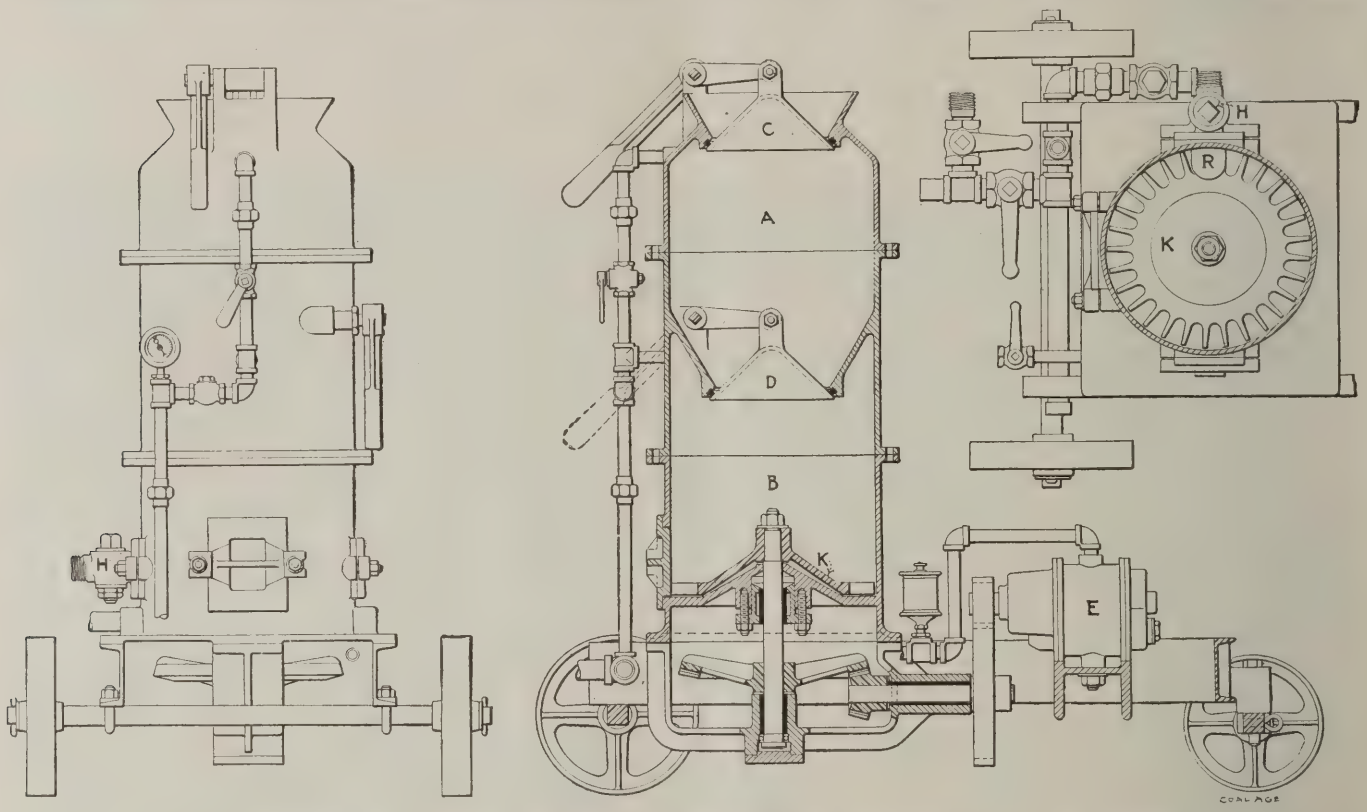
The feeder *K* is kept revolving through a spur- and bevel-gear train by the air motor *E* on the rear of the truck. It delivers intermittently yet with frequency at *R*, through the valve *H*, a measured amount of dry mortar from the storage chamber *B*. This is discharged under pressure by the air and passes through hose of pure soft rubber covered with heavy canvas. This is of any necessary length, and may be 300 or even more feet long.

On reaching the nozzle to which water is admitted from the pipe *P* by the valve *V*, the mix is thrown into the air in a concentrated stream at a speed of 110 ft. per second. The material is now hydrated for the first time. There is, therefore, absolutely no set in the mortar when it reaches the place of deposit.

There can be no question as to the amount of water to use. It must be sufficient to cause the mortar to adhere without running. If enough water is not added the

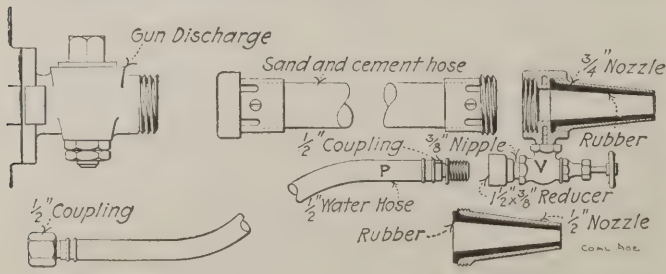
†May 11, 1912. Vol. 1, p. 1011.

gunite will not stay in place and the dust formed will inconvenience the nozzleman so that he will be sure to increase the supply. If too much water is used, it is expelled automatically by the force of the impact. The air also which might be expected to render gunite a scoria-like mass of cement bubbles, creates a material more dense than the best mortar owing apparently to the violence with which the mix is projected against the face to be coated.



Surface Coat of Pure Cement

When the mixture is first thrown against a surface, the sand fails to stay in place. Only pure cement will stick until the body is coated with that material. But the rebound of sand immediately ceases and the mortar begins to adhere as a whole, building grain upon grain. In this way there is no contact between the sand and the material coated. Every grain of sand is attached by a coating of cement to the reinforcement or backing.



Engineers who have been specifying that such a coating of pure cement be placed on all surfaces, before making an addition to work after a delay in building up a concrete structure, will appreciate the value of this automatic selective action of the cement gun and will realize why gunite holds with a grip of iron so strong that it is being projected on the surface of piles in harbor work before they are driven. After the gunite has been hardened, they will then bear driving by a 3000-lb. hammer to a 20-ton bearing.

Precautions against Wear of Hose

The hose, couplings and nozzle of the cement gun must be suitable or the wear will be rapid. The couplings fit on the outside of the hose so that there is a continuous lining of rubber. The nozzle also is lined with the same substance, to defend it against abrasion. This is necessary because there is a certain diameter of nozzle suited to a definite diameter of hose and if much wear took place the loss of air would be considerable. The nozzle is made with an annular ring at its larger end. The water is admitted to this ring, and is permitted to enter the outflowing stream of mortar by perforations in its periphery. Straight steel pipe may be used to transport the mix but on curved sections, rubber-lined hose is essential because a curved-steel pipe will wear out in a few hours' time. The rubber lining of the nozzle will last from one to three weeks. The material hose is from 1 to 1½ in. inside diameter and the hose delivering water to the nozzle is ½ in.

Elevations of Original Model of Cement Gun, Mounted on Four Wheels

Details of Material and Water Hose

The cement gun does not use much air. All that is needed is about 150 cu.ft. of free air per minute compressed to 45 lb. pressure, which is sufficient for the working of a gun at a capacity of 1½ cu.yd. of dry mortar per hour. A larger volume of air at a higher pressure will speed the machine up to 3 cu.yd. per hour.

Gunite Is a Superior Grade of Cement Mortar

As stated, gunite is superior to cement mortar as prepared by ordinary methods for there is no incipient set before placing; its adhesion is superior and its density a maximum. The report of Westinghouse, Church and Kerr shows that gunwork excelled handwork from 20 to 260 per cent. in tensile strength, 20 to 720 per cent. in

compressive tests, 43 to 1900 per cent. in surface impermeability, 40 to 430 per cent. in resistance to water absorption, 33 to 92 per cent. in the volume of voids, 27 per cent. in adhesion and 12 per cent. in weight.

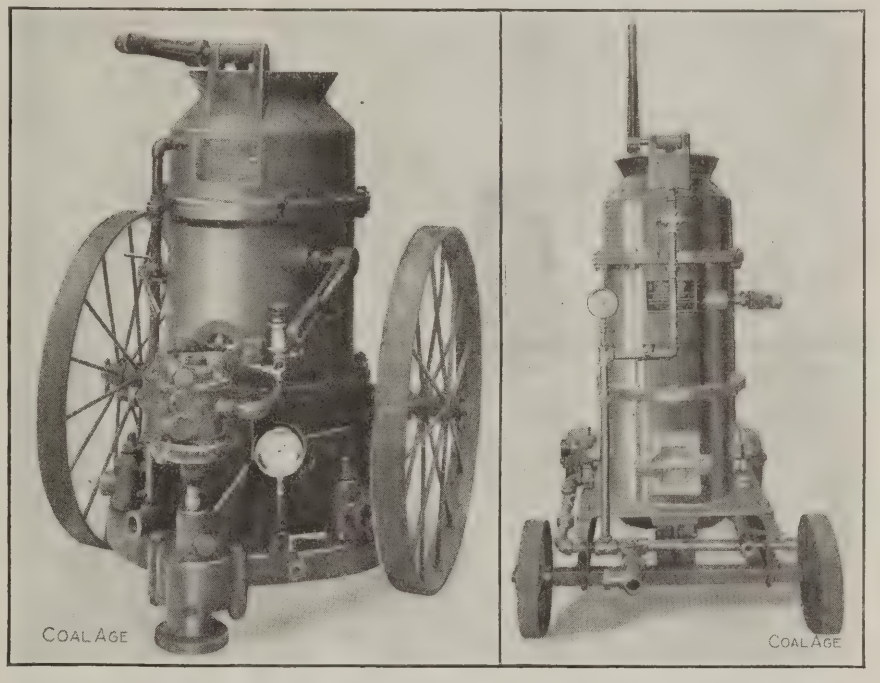
Hence, the only question as to whether to use gunite is not one of quality but as to the amount needed to justify the employment of a machine, for the price of application is lower than with handwork, and the coating being stronger need not be so thick.

Suitable for Refacing Mine Buildings

Gunite can be used for a great many purposes among others for coating frame houses. This makes them warmer, drier, stiffer, more fireproof and more permanent. The illustration shows the little town of Elba, N. Y. In 8 days, 15 houses were covered with a 1¼-in. covering of cement mortar. The actual time occupied was only 60 hr. 40 min.

Better results could have been obtained had the coating been only ¾ in. thick instead of 1¼ in. However, ⅞-in. furring had been supplied instead of ¼ in. and the thickness could not be kept down to the preferred figure. Small-mesh expanded-metal lath was used as reinforcement.

To perform this work the following labor was used: 1 gunman at $2.50, 1 nozzleman at $2.50, 1 foreman at $3.50, 3 laborers at $2, 1 engineer at $2.60, 2 plasterers at $5.50, the latter being union men. The total payroll per day was $28.10. In all, 1402 sq.yd. exclusive of openings, were covered at a labor cost of 14.2c. per sq.yd., using 434 bags of cement and 44 cu.yd. of sand. This figure, we are assured, is somewhat high for cement-gun work, the labor costs ranging from 8c. to 16c. per sq.yd., according to circumstances.



A Gunited Village at Elba, N. Y.

This method of coating houses inside and out is well suited for use in the building and repairing of mine villages. It can be used for power houses, office buildings and barns. If a fine finish is not needed, the employment of plasterers is unnecessary and except where an even coat is desired, there is no need for a skilful operator. The quality of the gunite is the same when made by a novice or a competent man.

Gunite May Be Used to Coat Steelwork

It is a desirable coating for steel tipples, headframes and bins. Being so impervious it protects the steel most effectively. Ordinary concrete of as lean a mixture as 1 to 9, can be filled in the heart of the box columns. The exterior of these can be encircled with reinforcement and coated with gunite. If desirable, however, this reinforcement can be used only on the top and bottom flange and the gunite be used to coat the flanges and web as shown in *C* in the illustration on the succeeding page.

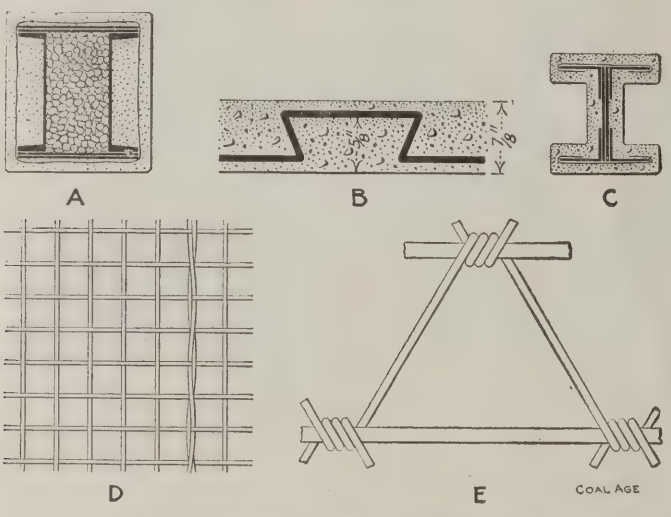
The More Recent Type of Machine Suited for Mine Work

The Original Type on Four-Wheel Truck

Gunite can also be used for tanks and reservoirs and for such purposes its imperviousness is strongly in its favor. The Twin Peak Reservoir at San Francisco is used partly for water storage and partly for an auditorium. When first built, it leaked at the divisional wall, but it was coated with a coat of gunite ¼ to ½ in. thick and now is water-tight, yet the head of water on the base of the wall is 27 ft. The cement gun would serve for coating boiler settings, making them impervious to the air. The coat might crack from the heat after a while but such destruction is to be expected of all such coatings and can be repaired.

Use Underground

Gunite can be used for fireproofing, drifts, mine roadways and stables. Where it is desirable to place a dividing wall between compartments in a shaft, the use of the gun is to be preferred, especially as the delivery of the material is conveniently effected through the medium of a hose.



It seems remarkable at first how largely gunite is used in connection with something so temporary as timber. Yet when we remember that it is cheaper than cement plastering, the reason is evident. Where it is desirable to secure a life for timber sets inferior perhaps to iron,

but greater than that of ordinary timber, the roof, ribs, sides and timbers could be coated by the cement gun, wire reinforcement being placed around the timbers and the posts being supported on a concrete footing. All this could be arranged without removing the timbers and so bringing down perhaps much of the roof.

When the roof tends to fall from oxidation or moisture, the cement will give it a permanent coat which will resist further weathering. It will not, of course, serve where the pressure is severe and the coal ribs are insufficiently strong.

Brattices and Stoppings

Gunite could well be used for stoppings and overcasts. For the purpose ferro-inclave reinforcing would be most desirable as it is not a mesh but a thin plate. Consequently, the gunite forms without difficulty on its face and back. The brattice could be made about 7/8 in. thick.

Reinforcement for Gunite Work

A, box column filled with 1:9 concrete wound with reinforcement and coated with gunite; B, ferro-inclave coated with gunite, suitable for new brattices; C, an I-beam with flanges covered with reinforcing and entire surface covered with gunite; D, Clinton electric welded wire; E, triangle mesh American Steel & Wire Co.

When wood brattices have to be replaced throughout the mine, thin cleats could be nailed on their faces and on these spread and nailed some form of reinforcement such as Clinton electric welded wire, 4x4x12x12 in., or the 7 or 7a triangle mesh of the American Steel and Wire Co., or larger expanded metal lath of some sort. When strength is not so necessary, poultry wire will serve instead of the more expensive reinforcing. Where brattices are to be built in front of old wood stoppings, the cement gun can then be used on one side only and the coating will cover the wire complete. It would be easy to make this cement work fit tightly to roof and floor whereas it is hard to connect poured-concrete work to the roof.

The mix is usually one part portland cement to three parts of coarse sharp sand passing through a 1/4-in. screen. Other compositions may be used, however, and hydrated lime, suitable coloring material or any other ingredients may be added such as are used with ordinary cement mortar without injury.

The preceding table gives data on which the performance of the cement gun may be estimated.

The Cement Gun is made by the Cement Gun Co., Inc., of 30 Church St., N. Y.

TABLE OF AIR REQUIREMENTS, CAPACITIES AND RESULTS OF THE CEMENT GUN

Duty per day 3/4 in. coat, sq.yd.	245	254	305	407	762
Duty per hr. 3/4 in. coat, sq.yd.	30.9	31.7	38	57	95
Duty per day 1 1/4 in. coat, sq.yd.	147	152	182	243	456
Duty per hr. 1 1/4 in. coat, sq.yd.	18.5	19.0	22.8	30.4	57
Number of nozzles used	One	One	One	One	Two
Diameter of nozzle, in.	1/2	3/4	3/4	3/4	3/4
Average air pressure at gun, lb. per sq.in.	30 to 35	38 to 40	40 to 45	50	30 to 40
Interior diameter, material hose, in.	1	1	1	1 1/4	1 1/4
Free air supplied compressor, cu.ft. per min.	110	135	150	175	210*
Rated delivery passed through gun, cu.ft. per hr.	25	35	40	50	85
Actual delivery	20	25	30	40	75

Note:—Results obtainable with the cement gun are affected by elevation above sea level, moisture and temperature of the air, quality of sand and its contained moisture, mechanical efficiency of compressor and the length of the transmission hose. The figures in this chart are based on an 8-hr. day, a 1 to 3 mixture of cement with sand and 100 ft. as average length of material hose.

* Air used for material hose only. Feed wheel driven separately by electricity.

The Traitor

By Berton Braley

Written expressly for Coal Age

He was a walking delegate,
A canny labor leader,
Exceeding clever in debate,
A smooth and ready pleader;
The miners thought him keen and wise,
To place and power they thrust him,
He was a hero in their eyes,
They thought that they could trust him.

But he was full of guile and craft,
A wiz at dealing double,
He held the owners up for graft,
He made the miners trouble,
The tricks he worked, the lies he spun
Would fill a lengthy docket,
For he looked out for Number One,
And blithely crammed his pocket.

He was a traitor to his cause,
Betraying friend and neighbor,
And breaking faith and breaking laws,
All in the name of Labor,
HE didn't care if famine came
And want and woe were showing,
For men were counters in his game
To keep his bankroll growing.

Yet when this foxy boy was caught
With all the graft he'd looted,
The workers cried, " 'Tis as we thought
Our leader's persecuted!"
And 'spite of proof and evidence
Of all his sales and barter,
And in the face of common sense
They made him out a martyr!

Rights under Illinois Mine Safety Law—The fact that the examiner of an Illinois mine had not marked a clod in a roof warranted a miner working under it in assuming that the examiner deemed the place safe, and the miner was not guilty of contributory negligence in remaining at work there. The coal company cannot escape liability for injury resulting from fall of the clod, because general instructions had been given employees in clearing out the mine to make all places safe. This precaution did not obviate the necessity for having the mine inspected and dangerous places marked, as required by the Illinois statutes. (Illinois Supreme Court, Piazzi vs. Kerens-Donnewald Coal Co., 104 N.E. Reporter 200.)

Automatic Safety Mine-Car Cagers

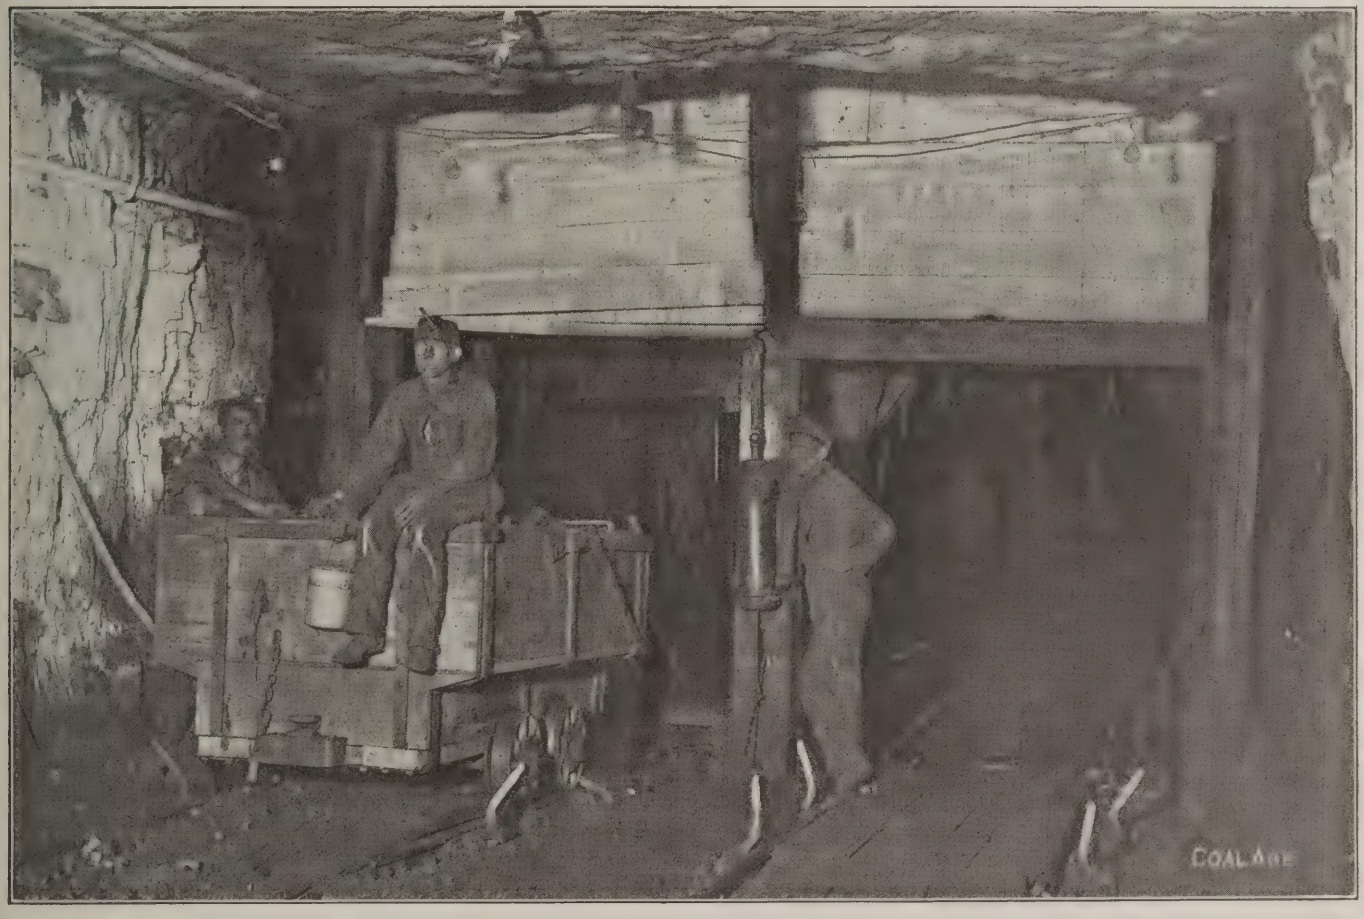
By E. G. Banta*

"There is a path which no fowl knoweth and which the vulture's eye hath not seen; the lion's whelps have not trodden it nor the fierce lion passed by it."

So wrote the inspired writer as recorded in a portion of Job; 28. Today the underground channels so vividly pictured in the chapter, as partly quoted above, honeycomb the earth in various localities for many miles and in the central bituminous district alone many thousands of men are employed in producing coal.

As in every other industry, machinery is being used more and more either to largely increase the working power of man or to safeguard him against the many accidents peculiarly incident to the production of fuel.

Many of these accidents occur in the handling of the cars at the shaft bottom and upon the tipples and inclines of the modern mine where whole trips frequently get beyond control of the workmen, expert though they are, and either pile up in the sump or run wild over the edge of the tipple, falling to the ground below.



In hoisting, coal is shaken from the car and falling down the shaft breaks hands, wrists, arms and heads of the men engaged in placing cars upon the cage.

The human body has its limitations and increased tonnage means not only additional labor for the men already employed, but an actual increase in their number. If all men so engaged were skilled and could be depended upon to always be at their places in the mine, accidents would be reduced materially but the human element is uncertain and unreliable.

One man takes sick and a green hand is substituted with resulting delays, accidents and wrecks. Another becomes careless, with similar results.

Quick, accurate caging, coupled with speed in hoisting assists materially in increasing the output of any mine and is necessary to the constant employment of those who operate the coal cutters and load the cars.

The accompanying illustration shows the shaft bottom at one of the mines of the Superior Coal Co., at Gillespie, Ill., equipped with an automatic safety mine-car cager, manufactured and marketed by the Mining Safety Device Co., of Bowerston, Ohio.

An Automatic Cager in the Mine of the Superior Coal Co., at Gillespie, Ill.

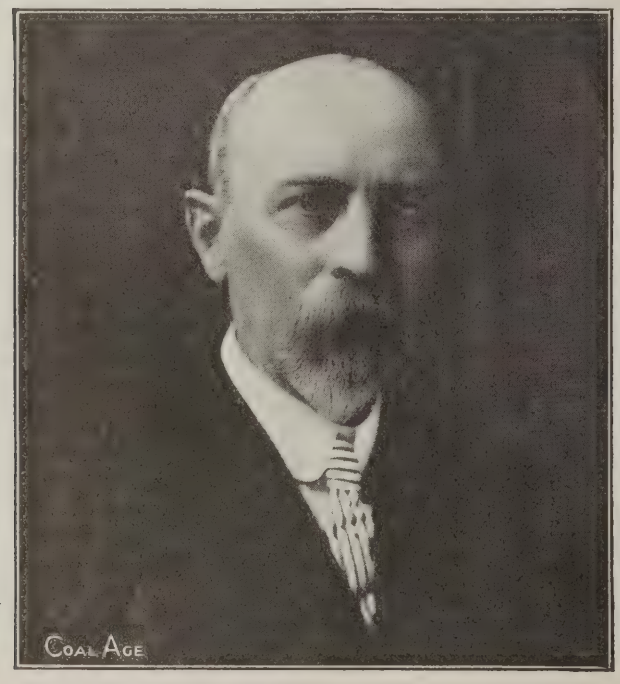
This cager is a single but effective automatic device, which installed at a shaft bottom does the work of the usual cagers, by taking the cars from the trips, one at a time, and placing them on the cage, accurately, safely and speedily. At the Nokomis (Ill.) mine of the Peabody Coal Co., these machines are feeding two cars, side by side, to the same cage.

In connection with these automatic cagers the same company is marketing a combination of automatic stops and angles which lock the car in position for hoisting.

These equipments are now to be found in mines in both the anthracite and bituminous districts of Pennsylvania, in West Virginia, Ohio, Indiana, Illinois, Iowa, Colorado, Alabama, Kentucky and Canada. It is claimed that their use is resulting in an actual saving in the handling of the cars of from ½c. to 1c. per ton.

412 Fairbanks Bldg., Springfield, Ohio.

Who's Who in Coal Mining



Edward V. d'Invilliers

Edward V. d'Invilliers is one of the foremost mining engineers and geologists in the United States. He was born in Germantown, Penn., Aug. 2, 1857. After attending a military school, Mr. d'Invilliers entered the University of Pennsylvania, from which institution he graduated with the degree "Bachelor of Science," in 1878. In 1913 his *alma mater* honored him with the degree "Doctor of Science."

Since becoming actively engaged in engineering and geological work, Edward d'Invilliers has made reports for some of the largest mining interests in America. His geological investigations of coal and ore measures in various states are particularly notable. He is at present a member of the Pennsylvania Topographic and Geologic Commission, and has contributed largely to the work published by that body. Some of Mr. d'Invilliers' contributions have appeared in the transactions of the A. I. M. E., the Geological Society of America and the Engineers' Club of Philadelphia. One of his most extended examinations covered the Pittsburgh coal region. Another important investigation, conducted by Mr. d'Invilliers, dealt with the iron ores and limestones of the Cumberland Valley.

He is a member of the Mining and Metallurgical Society of America, A. I. M. E., the Geological Society of America, the American Philosophical Society and the Franklin Institute.

Mr. d'Invilliers continues in the practice of mining engineering and geology, having his office at 518 Walnut St., Philadelphia, Penn.

EDWARD V. D'INVILLIERS

William Haven

William Haven is one of the leading coal operators in Iowa. He was born at Portsmouth, N. H., Nov. 11, 1845, and graduated from Norwich University, in Vermont, with the degree "Bachelor of Science" in 1863.

In 1869 Mr. Haven went west to Illinois and had charge of the construction of a section of railroad for the C., B. & Q. R.R. His connection with the coal industry of Iowa commenced in 1870, when he was placed in charge of three mines of the Union Coal & Mining Co. as assistant superintendent.

A few years later he organized the Whitebreast Coal & Mining Co. and was elected president of this corporation. On account of the good marketing facilities and excellent quality of the product, this company, for several years, was the largest shipper of coal in Iowa.

In 1882 Mr. Haven sold his interest in that company, at the same time agreeing not to engage in the coal business in that district for ten years. It was not until 1897 that he again entered the coal business, organizing what is known as the Inland Coal Co. This concern soon developed much territory in the Lucas County field, of Iowa, and placed the coal business of that section on a more substantial basis than ever before. Although the Inland Coal Co.'s mines were recently sold to other interests, Mr. Haven will be remembered as the pioneer operator of that particular field.

He is still a member of the Iowa Coal Operators' Association and deputy governor of the Iowa Society of Colonial Wars.

WILLIAM HAVEN

Editorials

One Way to Introduce Your Coal

"And there is no new thing under the sun." Possibly not, but here is an interesting variation.

A coal-mining company in Alabama has purchased a large quantity of coal scuttles and on each of these buckets they have had printed in artistic lettering, the name of their coal and a statement that it contains little ash. These buckets are now being sent out gratis to the various retail coal dealers who handle this particular coal exclusively, with the request that the buckets be filled with coal and distributed free to the households that are in the habit of buying their coal in small quantities from retail coal yards. The entire expense of filling the buckets with coal is borne by the wholesaler.

Brands of tobacco, baking powder, tooth paste and soda crackers have all been introduced in this manner; why not coal?

Manyana

The state of Pennsylvania is said to be still in existence and it is credibly reported that in 1912 it put some coal on the market, at least E. W. Parker so states, and he ought to know. But so far we have no state report of production and now we learn the bindery of C. E. Aughinbaugh, where the state publishes its belated reports, is burned down.

A part of the issue of Smull's legislative handbook for last year is destroyed and it is proposed that efforts be concentrated on the issue of 1914, which should have been published early in the year. We think this ill-advised and suggest that work be commenced on the entire bulletin issue of 1916, so that there may be no failure when that year arrives. Our attitude on the momentous issue is one of "watchful waiting."

The Operators of Central Pennsylvania

It is pleasing to note that the operators of central Pennsylvania have showed a disposition to meet their men and discuss the wage scale at the earliest possible moment. We confess we did not like to see a body of mine owners laying off their men because these men, not even suggesting a strike, *asked* for something which would involve the former in expense.

We are not accustomed to discharge, or even to suspend for ten days or two weeks that foolish employee who thinks he is entitled to a "raise." We usually discuss the question with him, and if we think he is not entitled to his demand, we are firm. He is no criminal that we should make him suffer and his family in the old-fashioned pre-Mosaic manner.

We are glad to acknowledge that there was no pressure of one operator on another to make him perpetrate so signal an injustice. Those who could not see clearly the falsity and the humor of the situation did not press their construction of what was appropriate on others.

On going to press, we understand that the men and operators are to meet at Clearfield, Penn., about Apr. 23 and it is sincerely to be hoped that their session will soon result in industrial peace. The demands of the men are reasonable and in accord with the present trend which would replace manual labor by mechanical, or at least animal power, but the miners cannot expect that this change will be made at the expense of operators, having to meet such competition as exists in Pennsylvania.

The list of bankrupted companies is too long and would be longer if a little such pressure were brought to hasten insolvency. If pushing cars is such an affliction, as indeed we agree it is, let the miners accept a reduction per ton mined in return for its abolishment and load a few more cars per year to recoup themselves.

District concessions are inconceivable where competition is so fierce. Inequalities usually exist only because such differences in scale are essential to the life of the industry in the region receiving them. There are, of course, large exceptions, and where such exist, the profits made in that section flood it with operators and raise by lowered price and increased royalties, barriers to wage adjustment which soon become insuperable.

One Great Item of Cost in Mining

Few people realize the heavy expense incurred by the hard-coal companies in their efforts to keep the anthracite mines dry. The latest estimate of the Pennsylvania Department of Mines places the total capacity of the pumps below ground in the anthracite field at more than 3400 tons a minute. This means that they are capable of pumping nearly 1,800,000,000 tons of water per annum.

At the present time these pumps are actually handling approximately 951,000,000 tons of water each year. Thus thirteen tons of water are lifted for every ton of coal mined. Such a quantity of water would fill a canal 10 ft. deep, 100 ft. wide and 4600 miles long.

At some collieries water is hoisted as well as pumped to the surface. In a shaft at Hazelton, a 2000-gal. tank (7.4 tons) is hoisted 95 times an hour. In the Pottsville region tanks holding 3000 gal. (11 tons) are in use. In the northern anthracite field, near Scranton, there is one mine where twin tanks are used, and 5100 gal. of water are hoisted each minute. In addition to the twin tanks at this mine, there is a 1000-hp. pump continually at work. This pump raises a column of water 16 in. in diameter 460 ft. in one minute. A modern pumping plant today costs from $25,000 to $30,000. Such an installation will discharge to the surface about 7000 gal. per minute.

The D., L. & W. collieries pump from 7,000,000 to 13,000,000 gal. per day, and at some of the operations of

the Susquehanna company, 9.3 tons of water are hoisted for every ton of coal. The Pennsylvania Coal Co. raises 7 tons of water for each ton of coal, the Delaware & Hudson Co., 14.3 tons, the Lehigh Valley Coal Co., 15 tons, and the Philadelphia & Reading Coal & Iron Co., 12 tons.

Facts of this nature furnish food for thought on the part of the public who complain about the high cost of their domestic fuel. The price of coal on board of cars at the mines today is very low when we consider the hazards of mining and the difficulties of production. One thing is certain, the mining companies themselves are not making an excessive profit from their operations. If the railroads and the retailers are securing more than is their due, the public should endeavor to adjust matters, commencing at the proper end. If an evil exists in the coal business, the blame should lie on the party at fault.

Rules, General and Special

Of all harmless phylacteries none are better opiates to conscience than the rules, general and special in many languages when we nail up on our tipples as men used to bind the Torah on their temples.

No one reads them and like the "speeches" of our statesmen, they are taken as read. We cannot blame any one, for these mandates are assuredly the driest of reading and men who rarely read or who read only with difficulty, will not spend the time to look them over.

But these rules should surely be read most carefully and we believe that the best way to contrive that this may be done, is by having them typewritten, one by one, month by month, and posted as bulletins. By using a different color of paper, interest would never fail. The little screed might be taken for a notice of a dance, a prize fight, a union meeting or a church gathering. Most probably everyone who could, would read it especially if it were written in every lanugage which the typewriter can print with a little help. We except, of course, from such a list of tongues, Greek, Chinese and Japanese.

No one can accept a hundred instructions at one time. They are best brought to the attention of the workmen one by one, and though to comply with the law, the rules still continue to be posted, there is no reason why they should not be publicly displayed in the manner suggested. In doing this, of course, the leading mandates can be quoted first.

A few of the "Don'ts" from the Bureau of Mines' Bulletins and from technical journals are suitable for publication in this manner. It would be well to quote the authority by which they are indorsed. We all are more mindful of the advice of strangers and of the regulations of governmental authority than we are of the rules of those whose follies and foibles we know too well. After all the objection of those who oppose safety regulations is often not so much to too much safety, but to too much Smith. They dislike advice and orders less than they do the adviser and disciplinarian.

The 100-Per Cent. Union

There seems a strong objection on the part of some coal operators to a 100-per cent. union in which they imagine all their miners are banded together against them. They rate abstention from union counsels as a sure proof of the friendliness of their men and look upon activity as a sure sign of discontent.

With this view of conditions, we would most strongly dissent. We can understand the man who would prefer to employ only nonunion men, but we cannot comprehend the attitude of the operator who, in recognizing a union, desires to have to deal solely with those to whom his wishes are anathema.

Better by far for him that the union draw into the fold, all those reasonable souls who believe that the domination of capital is an easy yoke, compared to the burdens which would be imposed on the world if the negligent, inefficient, discontented and visionary occupied all the high places. Far better is it that he should meet in debate, the average, composite intelligence of his men, rather than merely those who believe that the world is all wrong and that he is a chief among wrong doers.

It is the best wish for him that the union shall be representative of his men in the mass as the political ballot records or should record the composite judgment of all shades of opinion. In fact, he needs that the ferment of irresponsibility be toned down with those elements of society which perhaps lean in the direction of inertia.

When we hear men boast that the union contains but half the men, we are disposed to presage trouble for such operators rather than peace, for it is likely that at least half of these union men are factious by temperament and regard the union, not as a place of defence, but as a sally port of defiance. On the other hand in a union 100 per cent. strong, probably at least 75 per cent. of the men are approachable by justice and reason, and desire agreement rather than invite dissent.

We are not advocates of the closed shop because in our opinion, such a condition violates the rights of individuals to combine or refrain from combining at their pleasure. Nevertheless, granted that the men desire to amalgamate as a unit to make a collective bargain, we see in that unity, a guarantee of the operator that he will have to deal, not with an unreasonable body, but with a safe and sane aggregate of reflecting men.

The Saloonstead

Last week under the title "Conservation," we called attention to one of the unfortunate results of the present Western land laws. We wish today to direct the thoughts of our readers to another.

We think that much good would accrue if the United States government would in the sale of its public lands reserve the right to restrict and control the selling of liquor thereon. There is at least one coal company in the West which would make a nice revenue by the renting of its lands to saloon keepers and which doubtless could even erect such places as boarding houses and so profit even more directly from the profit of liquor selling.

It refrains from so doing and it is probable that thereby it would do much to make model towns if Uncle Sam did not himself make a profit which the coal company has spurned. For near the towns are tracts which may be and are bought by individuals as coal land.

The price is held too high at present to make the land attractive as a mining proposition, but it is admirable ground for the raising of saloons, pig's ears and questionable dance halls where fan-tan flourishes and the orientals aid the progress of degeneracy.

Discussion By Readers

Starting Longwall in Room-and-Pillar Work

Letter No. 1—Having noted the request for a general discussion of the question of opening a longwall face in a room-and-pillar mine, COAL AGE, Apr. 4, p. 587, and having had considerable experience in this kind of work, I offer the following:

In the mine to which I will refer, the coal was from 3 to 4 ft. thick and overlaid with a soft slate that ranged from 1 to 3 ft. in thickness. This was again overlaid with a harder slate that made a good roof. The mine had been opened on the room-and-pillar system, and 12 rooms had been turned off one heading and driven about 30 ft. when it was found necessary to abandon them, owing to the expense of maintaining a slate crew, which together with the extra cost for yardage and timbering, made it impossible to continue the work further on this plan.

The manager, knowing that I had formerly had experience in longwall work, asked me if I would undertake to open this section on that plan. I agreed to try, and first cut the 12 rooms into each other, at the face, and built up solid packwalls of slate and dirt, just back from the face. In places it was necessary to build chocks of timber filled with slate. By laying a good road in every fourth room, I was able to open out and work a longwall face from 200 to 250 ft. in length. I used good straight props and good cap pieces over each timber. Where the bottom was soft, I dug through the fireclay and set the post on a hard rock bottom.

The plan worked fine. Using a short-wall, Jeffrey machine, it was possible to make one cut the entire length of the face, to a depth of 6 ft. The result was a larger percentage of lump coal was obtained and the output greatly increased. For a 3-ft. seam, cut 6 ft. deep, counting a cubic yard of coal to the ton, the coal mined would average 2 tons for every yard of face cut. The loaders would move the slate while the motor was pulling the trip to the bottom and returning with another trip of empties.

In this system, practically no coal was lost, the entire seam being taken out clean. In some cases, it is possible to carry two or more independent longwall faces; one, say 50 ft. ahead of the other. In many cases, the only practicable scheme to adopt, to work the coal at a profit is to change from the room-and-pillar system to a longwall face such as I have described.

A. T. WADE.

Red Ash, Va.

Letter No. 2—Constant reader, COAL AGE, Apr. 4, p. 587, asks: "Can a common packwall system of longwall mining, with two or three sets of posts at the face, be made to successfully replace the room-and-pillar system, in a mine that has advanced about two miles." In reply to this question, I say yes, having made such a change myself in the following manner:

In Fig. 1 the full lines show the general plan of a mine working on the room-and-pillar system, while the dotted portion shows the extension of the workings on a longwall basis or system of working. The full lines show the extent of the room-and-pillar workings at the time when it was decided to make the change and put the mine on longwall work. At that time, the room-and-pillar workings consisted of one pair of main or face entries, to the right and left of which are shown the last two pairs of cross-headings, on which rooms are still working, as shown in the plan.

Having decided to change this plan of working for a longwall system, the first step to be taken is to stop the face entries, as well as all the cross-entries. Four men must be put to work at once to open what will be called the 19th level, right," which is to be driven to the right, at the head of the face entries, as shown on the plan. This roadway or level is to be driven 12 ft. wide, with a 12-ft. pack on each side, leaving a 5-ft. space between these packs and each coal face, or rib, making the entire width of the opening 46 ft. At the same time, four men are likewise started to open what will be known as the "19th level, left," in the same manner as just described. Both of these levels must be double shifted, in order to supply a sufficient number of working places for the men who are still driving rooms in the room-and-pillar workings. As places are ready for them in the longwall work, they are transferred from the room-and-pillar workings, to the former.

In the longwall work, "gates" or roads are maintained parallel to the face headings in the room-and-pillar work.

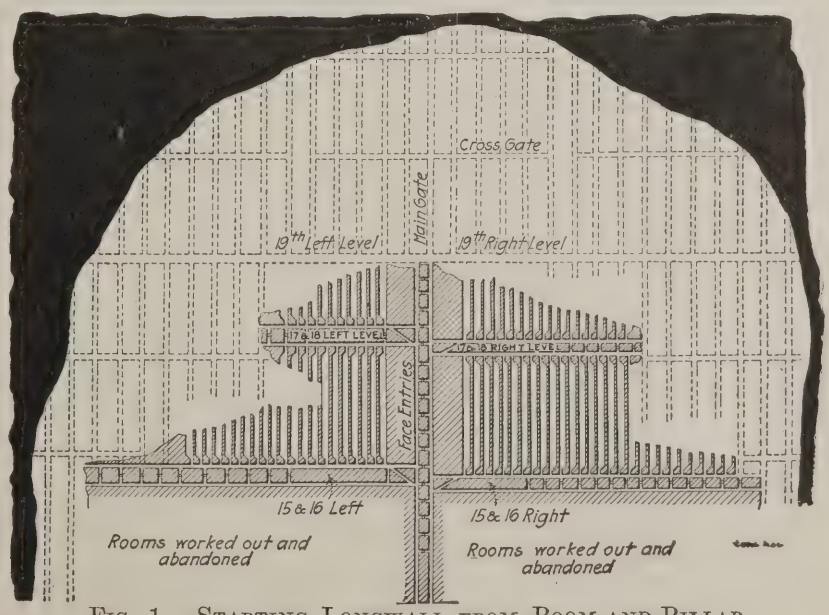


FIG. 1. STARTING LONGWALL FROM ROOM-AND-PILLAR WORKINGS

These gates should be 100 ft. apart if conditions will permit. At times, it may be found necessary to reduce this distance between gates; but it should be remembered that this will increase the expense of "ripping" and packing. The gate which is the extension of the main haulage road of the room-and-pillar workings, as well as the gates dividing the several panels, are "main gates." Each main gate takes the coal from five intervening gates on each side. This plan avoids the necessity of maintaining roads in each gate, after it is cut off by a cross-gate. The cross-gates are driven to the right and left of the main gates, at distances apart varying from 300 to 400 ft.

To provide for the proper movement of cars, it is necessary to put in a "parting" or side track on each main gate just off the level or cross-gate. As each cross-gate is finished, this siding is moved forward to the next cross-gate. The gates opened to the right of 19 right and the left of 19 left work the coal back to the room-and-pillar workings. Ordinarily, four men work in each gate, making 44 men to each main gate.

In Fig. 2, I have shown the proper method of arranging the packwalls and timbering the longwall face. The superintendent of every longwall mine should determine the proper distance apart for setting posts at the face.

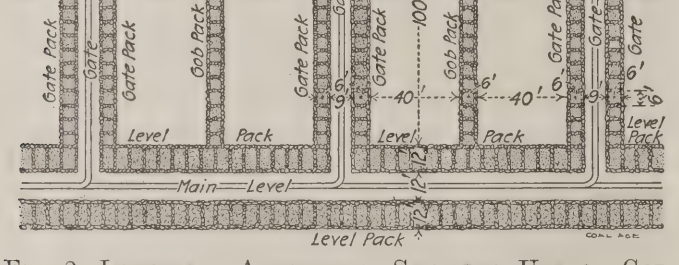

Fig. 2. Longwall Advancing, Showing Use of Gob and Roadside Packs

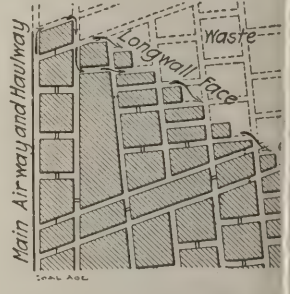
This is necessary because conditions differ in every mine, in this respect. On no account must posts be left in the gob or at gatesides, because they have a tendency to throw the weight on the coal face, which will frequently cause heavy roof falls that will obstruct the ventilation and cause unnecessary expense for removal.

Before finally deciding to change room-and-pillar workings, in a mine, for the longwall system, a competent longwall man should visit the mine, to study the roof conditions and give his opinion and advice. In the particular seam to which Constant Reader refers, there are 9 in. of soft slate underlying the coal and a 9-in. stratum of coal beneath that, underlaid again with soft fireclay that has a tendency to heave. This floor should be left severely alone, because if bottom is lifted, endless trouble will result from the heaving of the floor, causing extra expense to keep the roads open.

The advantages to be derived from working coal by the longwall system where it can be employed are as follows: 1. Practically 100 per cent. of the coal is extracted, which is from 10 to 15 per cent. more than in the room-and-pillar system. 2. The coal works more readily, which should reduce the price of mining, and the coal is less broken. 3. The workings are more easily ventilated, reducing the cost for bratticing and giving better air to the working face. 4. The distance of hauling the coal is generally reduced, for the same output per day, and there are fewer roads to keep open. 5. More men can be employed and a larger output obtained for the same area of mining than in the room-and-pillar system. 6. The "weighting" of the roof reduces the labor of mining the coal when proper advantage is taken of this factor in longwall working. 7. The expense and danger of blasting are practically eliminated.

It is important in longwall work that the "ripping" should be kept well up to the face, in each gate. Also, the packwalls should be solid and well built. Loosely built packs are crowded out into the roads when the weight comes on them.



Harry Marson.

Piney Fork, Ohio.

Letter No. 3—I was much interested in the inquiry of Consant Reader, Coal Age, Apr. 4, p. 587, in reference to starting a longwall face, from room-and-pillar workings. I have had 16 years' experience in longwall work, in England. In my opinion, a seam of coal from 4 to 4½ ft. in thickness, with a hard top, is favorable to longwall work. This system has numerous advantages, which may be stated as follows:

The longwall system of mining permits a larger percentage of extraction of coal than can be obtained in the room-and-pillar system. The ventilating current is made to sweep the working face; and, since the waste portions of the mine are closed tight, there is very little opportunity for the accumulation of gas in abandoned places. Less timber is required, and there is practically no expense for yardage.

The most successful plan of longwall work that I have ever witnessed was where the working face presented a broken line. This was accomplished by allowing one place to lead another by about 30 ft., as illustrated in the accompanying figure, showing a small portion of the workings. This plan had the effect of allowing each place to bear its own weight, with the result that it is almost impossible for a sudden weight to be thrown on the face that often results in a heavy cave. In general, the roadside packs should be from 9 to 12 ft. wide. As the work advances, cross-roads are started off the main road so as to cut off the gob roads leading to the face. The purpose of this is to cut down the long haul and reduce the number of roads to be kept up. The same rails can be used over and over again. All abandoned gob roads should be fenced off when the track and timbers are drawn.

Showing Broken Line of Longwall Face

In order to obtain the necessary headroom on the roads, the roof should be brushed instead of lifting bottom, particularly if the bottom is soft. The material taken from the roof over the roadways is then used for building packs at the side of the road. No timber should be left standing in the gob, as it will prevent an even subsidence of the roof on the packwalls and will often cause a sudden weight to be thrown on the face. With

suitable care, roof caves will seldom occur where the working face is advanced uniformly. In longwall work it is important to employ men who understand the system and know how to set the props and draw the back timber as the face advances.

In regard to changing the system of mining from room-and-pillar work to longwall, it is important to prepare for the first weighting of the roof. Cribs must be built every 4 to 6 yd. apart. The gob roads can be laid out from 60 to 70 ft. apart, on each side of the main road, which should be 12 ft. wide; and good solid road-packs should be built on each side of the track. Before making the change from room-and-pillar work to longwall, it is important to lay out a good plan and determine the position of the main haulage road, cross-roads and packwalls. As previously stated, unless substantial cribs and packs are built in a careful manner, the first weighting of the roof will destroy the face. When this is once controlled, the rest is easy. The main intake current is carried up the main road to the face by erecting curtains at the mouth of each cross-road. At the face the current is split, the air passing to each side and returning along the face and the gob roads to the upcast.

Universal, Ind.

The United Mine Workers and the National Guards

I was pleased to note the brief editorial, COAL AGE, Mar. 28, p. 531, commenting on the attitude assumed by the United Mine Workers of America in their convention held at Peoria, Feb. 27, at which time the convention went on record as being opposed to the National Guards as maintained in the various states.

The action of the convention, in this respect, is greatly to be deplored. Their contention that the guards are always on the side of capital and never on the side of labor is more of a reflection on themselves as representatives of a great class of workers than on the National Guards. It is the duty of the National Guards, when called upon to act in cases of labor disputes, to protect life and property that are menaced by the attitude of many of the strikers. In the performance of their duty, they frequently come into violent contact with those acting in opposition to law and order.

I do not wish to go on record as being opposed to unionism. On the contrary, I am a firm believer in the spirit of unionism—the spirit that prompts men to band together for mutual benefit and protection. But, when a union adopts a reactionary policy, in opposition to law

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

Summation of Potentials—When an air-current passes in succession through two or more airways of different section, the total unit pressure (lb. per sq.ft.) due to the circulation is equal to the sum of the unit pressures of the several sections. The arrangement, in this case, may be described as "tandem."

Likewise, in a tandem circulation, the total power on the air (ft.-lb. per min.) producing the circulation is equal to the sum of the powers absorbed in the several sections through which the current passes.

Indicating the potentials of the respective sections of the air course in a tandem circulation by X_1, X_2, X_3, etc.; and the corresponding unit pressures and powers on the air by p_1, p_2, p_3, etc.; and u_1, u_2, u_3, etc., respectively, remembering that the square of the pressure potential is equal to the cube of the power potential, as expressed by the formula

$$X^2_p = X^3_u$$

we can write the following:

For tandem circulations, calling the general mine pressure p_0 and the total power on the air u_0,

Mine pressure, $$p_0 = Q^2 \left(\frac{1}{X^2_{p1}} + \frac{1}{X^2_{p2}} + etc.\right)$$

or $$p_0 = Q^2 \left(\frac{1}{X^3_{u1}} + \frac{1}{X^3_{u2}} + etc.\right)$$

These formulas may be written more simply by indicating the summation of the potential factors by the character Σ; thus,

Mine pressure, $$p_0 = Q^2 \Sigma \left(\frac{1}{X^2_p}\right)$$

or $$p_0 = Q^2 \Sigma \left(\frac{1}{X^3_u}\right)$$

In like manner, the total power on the air or power producing tandem circulation in a mine is expressed by the formula,

Power on the air, $$u_0 = Q^3 \left(\frac{1}{X^3_{u1}} + \frac{1}{X^3_{u2}} + etc.\right)$$

or $$u_0 = Q^3 \left(\frac{1}{X^2_{p1}} + \frac{1}{X^2_{p2}} + etc.\right)$$

These formulas may be expressed by indicating the summation of the potential factors, as before; thus,

Power on the air $$u_0 = Q^3 \Sigma \left(\frac{1}{X^3_u}\right)$$

or $$u_0 = Q^3 \Sigma \left(\frac{1}{X^2_p}\right)$$

If desired, the part potential value can be used by omitting k when finding its value, and writing the k outside the parenthesis; but the relative potential obtained by canceling common factors cannot be used here. The relative potential, so much used in the calculation of the splitting of air currents, can only be employed when the potential appears as a ratio.

The Coal Age Pocket Book

Example—A shaft mine has been opened on the triple-entry system. The downcast and upcast shafts are each 600 ft. deep and 8x20 ft. in section. The main headings have been driven a distance of 2000 ft. from the shaft bottom. The center one of these headings is the intake and is 7x14 ft. in section, while the two side headings are the return airways for the respective sides of the mine and are each 6x12 ft. in section. On each side of the main headings cross-headings, 6x10 ft. in section, have been driven 500 ft.

If the intake air divides at the face of the main heading and equal currents ventilate the two sides of the mine, what power on the air will be required to circulate a total of 60,000 cu.ft. per min. in this mine, and what water gage will be produced in the fan drift?

Solution—The first step is to calculate the potential values of the two shafts, main intake, two cross-headings and two return airways, as follows, remembering that these being equal splits, it is only necessary to double the potentials of the cross-headings and return airways by taking twice the sectional area:

Shafts,	8 × 20 ft., 600 ft.;	a = 160 sq.ft.;	s =	67,200 sq.ft.
Main intake,	7 × 14 ft., 2000 ft.;	a = 98 sq.ft.;	s =	84,000 sq.ft.
Two cross-headings,	6 × 10 ft., 500 ft.;	$2a$ = 120 sq.ft.;	s =	32,000 sq.ft.
Two return airways,	6 × 12 ft., 2000 ft.;	$2a$ = 144 sq.ft.;	s =	144,000 sq.ft.

The part potential values are then as follows ,omitting k:

Shafts, $$\frac{1}{X^3_u} = \frac{s}{a^3} = \frac{67{,}200}{160^3} = 0.0164$$

Main intake, $$\frac{1}{X^3_u} = \frac{s}{a^3} = \frac{84{,}000}{98^3} = 0.0892$$

Two cross-headings, $$\frac{1}{X^3_u} = \frac{s}{(2a)^3} = \frac{32{,}000}{120^3} = 0.0185$$

Two return airways, $$\frac{1}{X^3_u} = \frac{s}{(2a)^3} = \frac{144{,}000}{144^3} = 0.0482$$

Sum of potential values, $\Sigma \left(\frac{1}{X^3_u}\right)$ 0.1723

The horsepower on the air in the fan drift, in this case, is found by substituting this general potential value, in the formula for finding the power in a tandem circulation; thus,

$$H = \frac{kQ^3}{33{,}000} \Sigma \left(\frac{1}{X^3_u}\right) = \frac{0.00000002 \times 60{,}000^3 \times 0.1723}{33{,}000} = 22.55\ hp.$$

The water gage, in the fan drift, due to this circulation, can be calculated in like manner, independently, from the same general potential value, by substituting the same in the formula for finding the unit pressure and water gage in a tandem circulation; thus,

$$w.g. = \frac{kQ^2}{5.2} \Sigma \left(\frac{1}{X^3_u}\right) = \frac{0.00000002 \times 60{,}000^2 \times 0.1723}{5.2} = 2.38+\ in.$$

The same result is obtained when the water gage is calculated from the power and the quantity of air in circulation.

and order, or any body of men permit themselves to be controlled by unscrupulous leaders, I am opposed to such leadership as dangerous.

It is folly to say that the *union* is always right, or to claim that *coal operators* are always right. I am opposed to the practice of operators bringing strike breakers to a field of contention, except when every honorable effort has been made and failed to induce the men to return to work. The importation of such workers, however, furnishes no excuse for the wanton destruction of property or the taking of lives that often results on such occasions. When the miner's sense of what is just and fair will not restrain him from lawless acts, he must be prevented by other means, and the National Guards is the institution created for that purpose.

It is generally the case that the governor is censured more frequently and more severely for not calling out the guards than for using this means of maintaining or restoring order. In my opinion, the only valid reason for discarding the services of the National Guards will be because they are no longer required. We may hope for the day to come when this will be true; but, for the present, we must recognize the fact that the National Guards is an indispensable factor of state government.

GEO. N. LANTZ.

New Straitsville, Ohio.

Removing Bark from Mine Timbers

The correspondent who suggested, some time ago, that bark should be left on mine timber is, I believe, in error. The bark certainly aids in the propagation of organisms that weaken the timber. Innumerable tests have demonstrated the truth of this fact.

In one instance, two pieces of fir were kept five months, one with the bark on and the other with the bark off. The compression tests, later, showed the former piece to have a breaking strain of 3,570 lb. per sq.in., the latter 3,385 lb.; for pine, the tests showed 2,716 lb. with bark on and 2,958 lb. with bark off; for oak, 2,133 lb. and 2,958 lb., respectively.

MINING ENGINEER.

Pittsburgh, Penn.

Correction

In the Study Course in Coal Mining, Apr. 11, p. 623, an error occurred in the calculation of the relative split potentials, for finding the natural division of the air current. As this error affected the remainder of the solution, we reprint those two pages corrected, below. The natural division of air given, p. 659, should also be corrected to correspond.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

The use of the "relative potential" value, in all calculations to determine the natural division of air between two or more airways, is one of the most important considerations in the saving of time and labor and avoiding unnecessary multiplicity of figures, which increases the opportunities for error and yields less accurate results. An example or two will serve to make this fact plain.

EXAMPLES IN NATURAL DIVISION

Example—An air current of 100,000 cu.ft. per min. is divided at the foot of the downcast shaft, between the following four air courses or splits, thereby providing two separate ventilation districts on each side of the shaft:

Split A,	8 × 12 ft., 6000 ft. long
Split B,	6 × 20 ft., 12,000 ft. long
Split C,	6 × 12 ft., 8000 ft. long
Split D,	4 × 6 ft., 1000 ft. long

All the splits are open to the free passage of the air, no regulators being used. (a) Find the natural division of the main air current or the quantity of air passing in each split. (b) What is the pressure due to this circulation? (c) What is the horsepower on the air?

Solution—(a) The first step is to calculate the relative pressure potential for each of the four air splits. The area, perimeter and length of each airway are as follows:

Split A,	$a = 96$ *sq.ft.*;	$o = 40$ *ft.*;	$l = 6{,}000$
Split B,	$a = 120$ *sq.ft.*;	$o = 52$ *ft.*;	$l = 12{,}000$
Split C,	$a = 72$ *sq.ft.*;	$o = 36$ *ft.*;	$l = 8{,}000$
Split D,	$a = 24$ *sq.ft.*;	$o = 20$ *ft.*;	$l = 1{,}000$

Instead of using these full values as when finding the true potential value of an airway, the lowest relative values for the areas, perimeters and lengths are used. These relative values are obtained by canceling the common factors in the areas, perimeters and lengths, separately, which gives

Split A,	$a = 4$;	$o = 10$;	$l = 6$
Split B,	$a = 5$;	$o = 13$;	$l = 12$
Split C,	$a = 3$;	$o = 9$;	$l = 8$
Split D,	$a = 1$;	$o = 5$,	$l = 1$

The relative split potentials are then found as follows:

Split A, $4\sqrt{\frac{4}{6 \times 10}} = 4\sqrt{\frac{1}{15}} = 4\sqrt{0.06666} = 1.033$

Split B, $5\sqrt{\frac{5}{12 \times 13}} = 5\sqrt{\frac{5}{156}} = 5\sqrt{0.03205} = 0.895$

Split C, $3\sqrt{\frac{3}{8 \times 9}} = 3\sqrt{\frac{1}{24}} = 3\sqrt{0.04166} = 0.612$

Split D, $1\sqrt{\frac{1}{1 \times 5}} = \sqrt{\frac{1}{5}} = \sqrt{0.2} = 0.447$

Sum of relative potentials..... 2.987

The Coal Age Pocket Book

Since the quantity of air passing in each split, in natural division is proportional to the corresponding potential, the quantity ratio is equal to the potential ratio, which is true also for the sum of the quantities and the sum of the potentials. Thus, the ratio of the quantity (q) passing in any split, to the total quantity (Q) in circulation, is equal to the ratio of the corresponding split pressure potential (X_p), to the sum of all the split potentials (ΣX_p).

$$\frac{q}{Q} = \frac{X_p}{\Sigma X_p}; \text{ which gives } q = \frac{X_p}{\Sigma X_p} Q$$

Therefore, substituting the relative potential values just found in this formula gives the following:

Split A, $q_a = \frac{1.033}{2.987} \times 100{,}000 = 34{,}570$ *cu.ft. per min.*

Split B, $q_b = \frac{0.895}{2.987} \times 100{,}000 = 29{,}960$ *cu.ft. per min.*

Split C, $q_c = \frac{0.612}{2.987} \times 100{,}000 = 20{,}500$ *cu.ft. per min.*

Split D, $q_d = \frac{0.447}{2.987} \times 100{,}000 = 14{,}970$ *cu.ft. per min.*

Total quantity..... 100,000 *cu.ft. per min.*

(b) Since the pressure is the same for all the splits, it can be calculated from any one of the given splits, by substituting the values for that split in the formula

$$p = \frac{k\,l\,o\,q^2}{a^3}$$

Thus, taking split A,

$$p = \frac{0.00000002 \times 6000 \times 40 \times 34{,}570^2}{96 \times 96 \times 96} = 6.48 \text{ lb. per sq.ft.}$$

(c) The horsepower on the air in the main entry, or the horsepower producing this circulation is, then,

$$H = \frac{Q\,p}{33{,}000} = \frac{100{,}000 \times 6.48}{33{,}000} = 19.6 \text{ hp.}$$

General Mine Potential—The potential value for the combined splits can be calculated from the total quantity of air in circulation and the resulting pressure, using the formula

$$X^3_u = \frac{Q^2}{p}; \text{ or } X_u = \sqrt[3]{\frac{Q^2}{p}}$$

Example—What is the general power potential for all the splits combined, in the example given above, where 100,000 cu.ft. of air was circulated under a pressure of 6.48 lb. per sq.ft.?

Solution—The general power potential for these combined splits is

Mine power potential, $X_u = \sqrt[3]{\frac{Q^2}{p}} = \sqrt[3]{\frac{100{,}000^2}{6.48}} = 1155$

Inquiries of General Interest

Room-and-Pillar System vs. Longwall

How does the room-and-pillar system differ from the longwall method of mining coal, in usage, cost and the methods employed for the extraction of the coal?

R. E. Wooden.

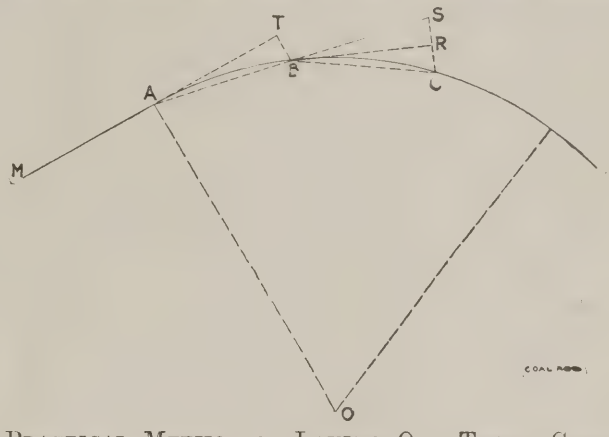
Cambridge, Mass.

In reply to this question, we would refer correspondent to the interesting discussion started in Coal Age, Jan. 10, p. 99. Much valuable information is contained in the letters, pp. 339, 419 and 458, following. The comparative advantages of these two methods of mining coal are enumerated in the letters discussing the question of starting longwall in room-and-pillar work, in this issue, pp. 697-9.

The longwall method of mining is used in preference to the room-and-pillar system, in the working of thin seams of coal, especially under excessive roof pressure, or where the complete extraction of the coal is important.

The cost of mining coal by the longwall method is generally less than that in the room-and-pillar system, owing to the more complete extraction of the coal, which is less broken and a less percentage of which is lost as fine coal and slack, in mining; less timber is used, the distance of haul is less and fewer roads are to be maintained; little or no powder is used for blasting the coal; the ventilation is better and more easily accomplished; a larger daily output is obtained for the same number of working places and men employed; there is less expense for handling waste, which in the longwall method is used for building packwalls, but in the room-and-pillar system must generally be taken out of the mine; there is less interruption of work and fewer accidents due to roof falls; mine fires are less frequent; and, finally, there is less damage to surface property, resulting from the extraction of the coal.

In the longwall method of mining, the coal is undermined by handpick or machine; and, by a careful and judicious system of timbering, the roof pressure is so controlled that it is utilized to break down the coal shortly after the sprags are drawn. In this method, little or no powder is used to break the coal. In the room-and-pillar system, the coal is undermined and sometimes side cut or sheared and then blasted down by drilling a hole in the coal face and firing a charge of powder sufficient to break the coal. In some cases, the coal after being undercut is wedged down by means of iron wedges driven close to the roof above the coal.



Laying Out Mine-Track Curves

Kindly ask, through Coal Age, or give me some information in regard to mine-track curves. In our mines we lay out all curves on a 63-ft. radius. The engineers give the point of curve, and the mine foreman measures 6 ft. ahead and offsets 7 in., in laying out the curve. Can you give me the formula for finding the chord and offset, in curves of different radius?

Adigo.

Burdine, Ky.

Referring to the accompanying figure, a common method of laying out track curves in a mine, starting

A Practical Method of Laying Out Track Curves in Mines

from the point of curve A on the straight track MA, is to extend the tangent MA to a point T, making AT any convenient or desired length, depending on the sharpness of the curve. In the case mentioned by correspondent, the chords AB and BC are each 6 ft. in length, and BS is equal to BC. The offset TB is called a "tangent deflection;" while SC is a "chord deflection." By the principles of geometry, the chord deflection SC is twice the tangent deflection TB; and a line drawn from B to R, the middle point of SC, is tangent to the curve at B.

The following formulas are used to calculate the chord deflection SC or the tangent deflection TB:

$$TB = \frac{c^2}{2\,r} = \frac{6^2}{2 \times 63} \times 12 = say\ 3\tfrac{1}{2}\ in.$$

$$SC = \frac{c^2}{r} = \frac{6^2}{63} \times 12 = say\ 7\ in.$$

In practice, it is convenient to use a short stick cut to the length of the chord deflection SC, and attached to two wires BS and BC, each the length of the given chord. By this means, the curve is quickly laid out, from point to point. The ends of the two wires BS and BC are attached to a small ring at B, through which a surveyor's stick pin can be passed.

To lay out a curve with this device, the stick pin is passed through the ring and first stuck firmly in the ground at the point of curve A. The center of the stick R when the wires are drawn taut is then lined in with the tangent MAT, and the end of the stick (C) then marks the first point B in the curve. The pin is now moved to B and the operation repeated, except that, now, the end of the stick (S) is made to line with the chord AB, when the other end C will mark the second point in the curve.

Examination Questions

Miscellaneous Questions

(Answered by Request)

Ques.—(a) Define the different electrical units and say to what they refer. (b) An electrical machine works at 150 volts and 25 amp.; what is the horsepower of the machine?

Ans.—(a) The four simple electrical units are the following:

1. The *ampere,* which measures the volume, commonly termed the strength of the current.

2. The *volt,* which measures the pressure or intensity of the current. In speaking of electricity, the voltage of a current is commonly referred to as the electromotive force.

3. The *ohm* or unit of resistance, which serves to measure the amount of resistance offered by a conductor to the flow of the electric current.

4. The *watt* or unit of power, which serves to measure the power of the electric current. One horsepower is equivalent to 746 watts.

(*b*) The horsepower in this case is

$$H = \frac{150 \times 25}{746} = 5+ hp.$$

Ques.—Where and when would you enter and make out your daily report, after completing the examination of the mine, in the bituminous region of Pennsylvania?

Ans.—The Bituminous Mine Law of Pennsylvania (Art. 5, Sec. 2) requires that a suitable record book shall be kept at the mine office on the surface; and that the fireboss, immediately after completing the examination of the mine, or any portion thereof, shall enter in said book, with ink, a record of such examination and sign the same. This record must show the time taken in making the examination and also clearly state the nature and location of any danger discovered in any room, entry or other place, in the mine.

The same section of the law provides, also, that such a record book may be kept at a station located in the intake entry of the mine; but, in this case, the fireboss is required to sign also the report entered in the record book in the mine office on the surface.

Art. 8, Sec. 3, of the same law requires a like daily record to be made in a similar book kept at the mine office, by the person whose duty it is to examine the ropes, links and chains in the hoisting shaft at least once in 24 hours.

Ques.—If, in the examination of a mine, the air current was found charged with gas to the explosive limit when the air was not completely saturated, what would be the explosive condition of the same air current after complete saturation had taken place?

Ans.—The effect of an increase in the degree of humidity of the mine air on its explosive condition is somewhat questionable. While it cannot be denied that, in the event of ignition taking place, the evaporation of a larger amount of water, per unit of volume of gas-charged air, will result in the absorption of a corresponding amount of heat and will, to that extent, modify the violence of the explosion by decreasing the temperature developed in the ignition, this effect is generally conceded to be practically inappreciable. The chief point in question, however, is whether the saturated condition of the air would have any practical effect to raise or lower the point of ignition of the explosive mixture.

The purpose of saturating the intake current of a mine, which is generally conceded to be good practice, is *not* to decrease the explosibility of the air; but to carry the moisture thus absorbed by the air current into the mine, and thereby prevent the absorption of moisture from the mine workings by a dry air current. In answer to the question asked, we think it may be safely stated that the increase of saturation in the mine air will not appreciably affect its explosive condition.

Ques.—A tract of coal land contains 1500 acres; the coal lies 500 ft. below the surface; the seam is 4 ft. thick and underlaid with 3 ft. of fireclay, beneath which is 4 ft. of sandstone. Above the coal is 5 ft. of slate and the measures overlying the slate are sandstone and shale. The coal is known to give off gas. How would you proceed to open and develop this property, to produce 1200 tons of coal per day of 8 hours?

Ans.—To provide for a daily output of 1200 tons of coal, it is necessary to estimate on, say 400 miners, 200 loaders, 15 drivers and the same number of mules, 25 bosses, daymen and boys, making a total of, say 640 men underground. The mine being gaseous, provision must be made for not less than 200 cu.ft. per man, and from 500 to 600 cu.ft. per min. per mule. The total volume of air required to fulfill these requirements should not be less than, say 150,000 cu.ft. per min.

A three-compartment shaft should be sunk to the coal, providing two hoistways, say not less than 6x9 ft. in the clear, each, and one manway of the same dimensions making the size of the shaft, say 9x20 ft. in the clear. This hoisting shaft should be made the downcast for the mine. The mine should be opened, preferably, on the four-entry system, providing two intake haulage roads, one for empties running into the mine and the other for coal coming out, and flanked by two return airways, one for each side of the mine. This main-entry system should be driven on both sides of the shaft, thereby providing four separate sections of the mine, each having a separate ventilating current and each producing on an average 300 tons of coal per day. The main-haulage roads should be driven 6x10 ft. in section, while the return airways may be driven 5x12, or, preferably, 5x14 ft. in section, to avoid the handling of an unnecessary amount of slate taken from the roof. The bottom should not be disturbed.

If conditions will permit, better results will be obtained by working this seam longwall. If surface conditions are favorable, the shaft should be located centrally in the property, so as to reach as large an area of coal as practicable. Conditions, however, must determine both the number and location of shafts required.

Coal and Coke News

Washington D. C.

It has been understood that the investigations of the Interstate Commerce Commission into the doings of the anthracite coal roads would be resumed on Apr. 22 and that at that time the roads would be allowed to continue their presentation of the case to its completion, setting forth all of their rates and practices.

The inquiry as now planned is to be the most extensive the commission has ever undertaken. The immediate defendants number nine: Reading, Jersey Central, Lehigh Valley, Delaware & Hudson, Lackawanna, Erie, with the New York, Susquehanna & Western, and Pennsylvania with the Northern Central. As a matter of fact, all roads east of the Mississippi are named as nominal defendants to the investigation, although the case naturally centers around those above named.

The investigation was started by the commission of its own volition, and most elaborate statistics have been asked of the nine defendant roads.

There have been several cases before the commission against hard-coal rates, but all in which a finding was made affected only individual roads.

Thus, the so called Marian Coal Co. case filed in 1910 which resulted in reductions of rates from the Wyoming district to Hoboken affected the Lackawanna. The celebrated Meeker complaint involved rates on the Lehigh Valley to Perth Amboy and in that case rates on sizes larger than buckwheat were marked down. Going further back, the suit of Coxe Bros. vs. Lehigh Valley in 1888 and Haddock vs. the Lackawanna in 1890, affected only special rates and the reductions were never put in force.

The so called Hearst case of 1902 was broad in its scope, but as the evidence advanced it was almost entirely rates to tidewater that were discussed, and no finding was ever made. This case was up before the commission in 1905, reopened by the commission in 1906, reargued again that year and then lapsed for almost 8 years, and was finally dismissed only last February, this action undoubtedly being taken in view of the present investigation.

Progress in the Freight Rate Case

Further progress with the freight rate case before the Interstate Commerce Commission has confirmed the belief that the commission does not intend to consider the granting of higher rates to the coal carrying roads if that can in any way be avoided. The turning of the discussion to the financial condition of the roads as has now been ordered by the commission is considered to be an exceedingly favorable symptom by those who have been opposed to the advancing of coal rates. In their judgment the roads chiefly concerned in the carrying of coal are in so favorable a financial situation that they will not be able to make out any sufficient case for higher rates from the standpoint of necessity except insofar as they demand these rates in order that they may be able to equalize their charges with those of the other railways which have been calling for an advance.

It had not been expected that the commission would go into the financial aspect of the roads in connection with this investigation of the proposed advance rates demanded, indeed it had been some time ago expressly stated that the commission thought it unnecessary or undesirable to undertake that phase of study. Just what has changed the point of view in this way is not altogether clear, but it is supposed that the principal factor has been the constant effort of the railroads to show that the advance in the rates is necessary to them from the mere standpoint of keeping their heads above water.

In the judgment of members of the commission, it is understood, the discussion of finance will show that in the case of some roads which are primarily devoted to the carrying of specified classes of commodities, the demand for an increase on this ground is misleading. The coal roads for instance, or those which are largely engaged in the transportation of coal in all parts of the country are believed to be conspicuously in this position.

HARRISBURG, PENN.

Denial of the existence of collusion between the Lehigh & Wilkes-Barre Coal Co. and the Central R.R. of New Jersey, in regard to the settlement of accounts or other financial business, was made on Apr. 14 by officials of the coal company at the resumption of hearings in the anti-trust suit of the Federal Government against the Reading and other groups of anthracite companies.

W. C. Johnson, comptroller of the coal company, testified that coal is sold to the Central R.R. of New Jersey at the same prices as are charged to other consumers. The coal company and the Central R.R., which controlls it through majority stock ownership, keep entirely separate accounts.

Testimony along similar lines was given by C. F. Huber, vice-president and general manager of the Lehigh & Wilkes-Barre Coal Co. He also asserted that the statistics known as the "Griffith" tables prepared about 18 years ago, and purporting to show the extent of the unmined coal in Pennsylvania are erroneous.

S. D. Warriner, president of the Lehigh Coal & Navigation Co., testified that this company is entirely independent of connection or association with railroad business.

Further testimony, intended to show that separate organizations and managements are maintained for the coal mining and coal transporting companies was given on Apr. 17, when hearings for the defense were resumed.

W. G. Brown, secretary of the Philadelphia & Reading Coal & Iron Co., said that his company paid the Philadelphia & Reading Ry. the regular tariffs for transporting coal. On cross-examination for the Government, he admitted that George F. Baer is president of both companies and is an active director of the coal and iron company. He conceded that on monthly balances the coal and iron company was always debtor to the railway, although only the customary 60 days' credit was extended.

W. J. Richards, vice-president and general manager of the coal and iron company, testified as to the great technical difficulties experienced in coal mining in the Schuylkill region. Although the Government objected to his testimony as irrelevant and immaterial, it was embodied in the records.

Mr. Richards said his company had spent $12,374,000 in improvements during the last 12 years, but no new lands were acquired. He gave the cost of production of anthracite coal, in the fiscal year ending June 30, 1913, as $2.35 per ton, although in a statement rendered to the Interstate Commerce Commission the company had given the cost in November, 1912, as $2.282. Mr. Richards explained that the difference was due to the larger amount of coal mined in the fall of 1912, a period of record-breaking production, which lessened the cost per ton somewhat, owing to the fact that certain charges are constant whether much or little coal is produced.

A Lengthy Litigation

A suit started 25 years ago by the Reading Ry., to stop the mining of coal underneath Mahanoy Plane, was decided on Apr. 13. So long drawn out was the litigation that several of the masters appointed to take the testimony died before they could make a report.

Ex-Congressman James B. Reilly, who was appointed as the fourth master, made a report on the above date, which sustains the Reading Co. in obtaining the injunction, which compelled independent operators to allow pillars to remain to support the surface of the earth. But on certain tracts where more pillars were demanded than necessary the independents were awarded $36,696 damages and the costs were also placed on the railroad company.

A large proportion of the anthracite coal sent to market by the Reading Ry. Co. is hoisted over Broad Mountain by means of gigantic stationary engines at Mahanoy Plane and it was important to the railroad to prevent any disturbance to the Plane by mining underneath.

PENNSYLVANIA

Anthracite

Larksville—Orders from Delaware & Hudson officials on Apr. 16 closed three collieries. These are Nos. 4 and 5 and the Boston, giving employment to 1500 men and boys. The officials claim that each of the collieries is in need of repairs and that because of the slight demand for coal these can best be made at this time. It is expected that the collieries will be idle for many weeks.

Freeland—Electricity is displacing steam at the Harwood colliery. The steam hoisting apparatus has been discarded and electric hoists substituted. The boiler house will be abandoned, as there is no further use for it. The only engine operating under steam pressure is a big first-motion hoisting engine which will be displaced in time.

Leviston—The few remaining miners that reside at Leviston have been asked to vacate on account of the stripping of the Lehigh Valley Coal Co., which is in close proximity to the town. The ground that is now occupied by the houses is desired for a dumping ground for the clay and rock that are being removed from the coal beds.

Scotch Valley—Coal-mining operations have taken on a new lease of life at the mines of the Beaver Valley Coal Co., where two steam shovels are now in operation opening a large stripping.

Pottsville—A corporation was made the defendant in a criminal suit for the first time in many years when a case was returned to court Apr. 16 by Justice McShea against the Lehigh & Wilkes-Barre Coal Co. The information sets forth that the defendant corporation operates a coal mine near McAdoo and has failed to keep a record of the number of cars of coal mined and loaded as required by law.

Bituminous

Carrolltown—The No. 1 mine of the Ebensburg Coal Co. at Colver, made a record in production for the month of March when 89,000 tons of coal were shipped. All this came from a single opening, and a 3½-ft. coal bed. It is believed that this record has seldom been surpassed under like conditions.

Pittsburgh—It is reported that Connellsville coke makers have shut down many ovens, the H. C. Frick Coke Co. interests alone having closed 1300 ovens recently.

Indiana—An attempt to destroy a hall being erected for the use of the United Mine Workers at Iselin was recently made. Returning to work after the lunch hour, John Ties, foreman of construction crew, found 26 sticks of dynamite beneath the building. A burning fuse had almost reached the explosives. This was, however, successfully extinguished by the foreman.

Canonsburg—Stringent orders have been issued by the Pittsburgh Coal Co. that hereafter its mine foremen, assistant foremen, firebosses, machine foremen, and drivers must sever their connections with all clubs which have sideboard attachments. This order has been sent to all the company's mines in Washington County.

Sharon—After ten years of successful operation, the coal mine on the Fogel farm near New Wilmington was abandoned Apr. 18. This is the last of about 50 of the smaller mines that have been operated during the past half century between Bethel and Sharpsville.

Rockwood—It is reported here that a Pittsburgh coal syndicate has notified farmers and optioners of the 10,000-acre tract in Milford Township to prepare deeds for the mineral underlying their farms. It is said that the Western Maryland R.R. will cross the river into this new coal field.

WEST VIRGINIA

Fairmont—Fire and an accident effectually put two mines of the Austin Coal & Coke Co., at Austin, out of commission recently. The fire destroyed the tipple of No. 1 mine with a heavy loss, which was partly covered by insurance. A large crowd gathered and someone entered the No. 2 mine, and released an electric motor at the head of a steep slope. This machine ran down the incline and wrecked at the bottom, effectually shutting down Mine No. 2.

Charleston—Declaring that they would rather shut down their mines than operate them at a loss, the coal operators of the Kanawha field on Apr. 17 refused the demand of the United Mine Workers for an advance of 10 per cent. and asked the men to accept a cut. Among other things the operators seek a reduction of four cents per ton run of mine in the Big Vein territory.

Bluefield—Despite the reported depression in other coal fields, the Norfolk & Western region appears to be more than holding its own as is shown by the official report of traffic over that road during the month of March. This showed an increase of 560,140 tons over the shipments for the preceding month, and 460,960 tons over the shipments from the same sources for the corresponding month of last year. The figures for the total shipments are in March, 1913, 1,751,158 tons; March, 1914, 2,112,118 tons. Coke shipments reached a total of 71,620 tons, all coming from the Pocahontas field.

KENTUCKY

Harlan—Coal operators in Harlan County are directly interested in the newly organized Harlan County Forest Protective Association, which represents in its membership the owners of over 150,000 acres of timbered land. Conservation of the lumber through prevention of forest fires is one of the objects of the association, and the coal men are cooperating in the campaign. The timber of Harlan County is of immense value in connection with the coal industry, since it is estimated that one acre of timber will mine about three-quarters of an acre of coal.

Whitesburg—Preliminary work in preparation for extensive coal-mining operations at Penny, just over the Letcher County line, in Pike County, have been begun under the direction of former manager John G. Smyth, of the Consolidated Coal Co. Six hundred houses will be erected and several good business blocks for the accommodation of the several thousand men who are to be given employment.

Jenkins—Coal-mine owners and miners in this section of Kentucky are hopeful for favorable consideration by Congress of Representative John W. Langley's bill providing for the appropriation of $50,000 to establish here a mine-rescue station and an expert station for analyzing and testing coals, lignite and other minerals and substances.

Lexington—Professor H. D. Easton, of the College of Mines and Metallurgy, Lexington, Kentucky, has issued a call to all the men who have attended the Practical Miners' Course to meet on May 8 for their first reunion.

This eight weeks course was first held during the summer of 1908 and has been held each summer until the present year when it was opened on Apr. 1 with an enrollment of 30 practical miners representing all the important mining counties in the state. Kentucky State University was probably the first college to offer instruction of the nature needed by men preparing for mine foreman examinations, but other colleges have now taken up the same line and are offering similar courses.

The date of the reunion has been set so that the men can attend the annual meeting of the Kentucky Mining Institute and the state-wide First Aid Contest to be held in Lexington on May 8 and 9. As a special feature, the U. S. Bureau of Mines will have its explosion gallery on the contest field and give demonstrations with it.

OHIO

Athens—The Luhrig Coal Co., which has been operating a mine on the B. & O. S. W. west of Athens, has started to dismantle the tipple and plant to move into West Virginia.

Cleveland—The Rail and River Coal Co. brought suit Apr. 16 in the Federal Court to test the constitutionality of the Green anti-screen law passed by the last Legislature, which provides that the miners shall be paid for all the coal they dig. The operators closed their mines on Apr. 1 stating that the enforcement of the Green law destroyed their ability to compete with Pennsylvania and Indiana operators. A favorable decision will probably hurry a cessation of the present shut-down of all Ohio mines.

ILLINOIS

Marion—The Donnelly-Koennecke Coal Co., operating for many years north of Carterville, in Williamson County, has been declared bankrupt, and W. O. Potter, of this place, has been appointed receiver.

Royalton—A slope, 50 ft. deep, has been driven from the north workings of the South Mine of the Franklin Coal & Coke Co. here, to the lower vein. Several months ago, in working northward through the mine, the coal disappeared. Borings indicated the vein 50 ft. farther down, and this condition existed for two or three miles across the tract. No more coal will be worked from the upper vein. The coal of the lower vein is of superior quality.

Harrisburg—Several collieries of the O'Gara Coal Co. have closed down for repairs, the time of suspension being indefinite. This will, however, probably last about three months. The mines affected are Nos. 3, 4, 9, 14 and 15. Some of this company's mines in Indiana are also closed down, and two carloads of mules have been shipped therefrom to Illinois where they have been placed in pasture.

Peoria—The coal operators on Apr. 16 flatly refused to accede to the demand of Illinois mine workers for higher wages. The operators have to date rejected practically every demand made upon them.

ARKANSAS

Fort Smith—Sixteen thousand union miners in District No. 21, embracing Arkansas, Oklahoma and Texas, are reported to have voted to accept a renewal of the present wage scale for the next two years at a vote taken on the proposi-

tion on Apr. 14 at Fort Smith, Ark. The alternative was to strike after July 31, when the present agreement expires.

The Bache-Benman Syndicate intends resuming operations under the open-shop policy at Prairie Creek Mine No. 4, Prairie Creek, at an early date. This was indicated recently when it became known that the plant which had been closed for more than a week as the result of a riot had been placed under guard again.

COLORADO

Ludlow—Thirteen men were killed and about 40 wounded on Apr. 20, as the result of a 14-hr. battle waged between militiamen and striking miners. During the fighting the big tent colony was destroyed by fire and hundreds of women and children are being cared for by citizens. It is reported that the militiamen lost three privates, one killed and two wounded, while the remaining casualties were sustained by the strikers. It is reported that "General" Louis Tikas, a strike leader is among the dead.

FOREIGN NEWS

Leeds, England—A settlement of the Yorkshire coal miners strike was reached Apr. 15, when the men voted to resume work. The strikers numbering about 170,000 quit on Apr. 2, demanding the introduction of a minimum wage scale. A conciliation board was appointed to discuss the points at issue, and succeeded in obtaining the men's consent to the taking of a ballot.

PERSONALS

Col. W. R. Lynn, formerly with the Caldwell Coal Co., of Muhlenberg County, Ky., has become general salesman for the Coil Coal Co. and will represent that company in Southern territory.

R. W. Overall has been made general manager of the Reinecke Coal Co. in this city, succeeding the late Fred C. Reinecke. Mr. Overall, who is also assistant secretary, has been connected with the Reinecke company for 26 years.

R. D. Norris was recently elected president of the Anthracite Division of American Institute of Mining Engineers. Four vice-presidents were also elected, W. J. Richards, Edwin Ludlow, Arthur Storr, and B. F. Huber. At the same meeting Charles Enzain was elected secretary treasurer.

G. W. Ireland, through the reorganization of the office management of the Jamison Coal & Coke Co., became sales manager of the coke department. Richard Donaldson was made manager of the coal department, both offices being formerly handled by the late Mr. Johnson as general sales manager.

Edward I. Martin, of Columbus, Kan., has been appointed receiver for the Pratt-Durkee Coal Co., operating near that city. The receivership was established at the request of officers of the company, who found themselves unable to meet their bi-weekly payroll because of lack of ready funds. The mine will be continued by the receiver for the benefit of creditors.

William Hahman was recently appointed receiver for the Lilly Coal Co. This firm is perfectly solvent having no debts whatever, and the duties of the receiver will be to establish the interests of the company in the properties held by it, to collect all indebtedness due the firm and make proper distribution of the assets among the partners. The receivership was caused by the death of Dr. H. J. Evans, some difficulty arising in the settlement of the interests of the estate of the decreased in the valuable property and assets of the company.

OBITUARY

J. S. Wiley, a prominent Iowa operator, died at the Red Cross Hospital in Kansas City on Apr. 17. He was 75 years old. Mr. Wiley retired from active business two years ago. Prior to that time he was president of the Marquette Third Vein Coal Co. The body was taken to Davenport, Iowa, for interment.

U. S. Stafford, outside mine foreman of the Consolidation Coal Co., at Chiefton, W. Va., died recently after an illness of a few days. Mr. Stafford was a native of Preston County, belonging to a well-known family in that section of the state. For the past 15 years he has been located at Chiefton, coming there about the time of the opening of the mining plant. He was an experienced man in the mining business, and was one of the valued and trusted employees of his firm. At the time of his death he was 48 years of age, and is survived by his wife and four children.

Stephen Wolschlag, familiarly known to many residents of Peoria, Ill., as "Steve," died there a short time ago in Proctor Hospital. Mr. Wolschlag was 57 years old. He was born in Peoria County, Ill., spending his early youth on a farm and later working in the distilleries. Some 20 years ago he began his career as a coal operator, forming a partnership with James Milliard, under the firm name of Milliard & Wolschlag. This venture proved a success and 15 years ago he organized the Wolschlag Coöperative Coal Co., which soon became one of the best known coöperative concerns of the state. About a year ago, however, Mr. Wolschlag turned this property over to Ditewig & McElwee, but continued in active management of the mine. In January 1914, he was appointed by Governor Dunne a member of the Illinois Mine Rescue Commission.

RECENT COAL AND COKE PATENTS

Soot Blower. G. P. Brown, Chicago, Ill. 1,086,751, Feb. 10, 1914. Filed Oct. 26, 1911. Serial No. 656,967.

Mine Car. J. J. Roby, Cleveland, Ohio. 1,087,318, Feb. 17, 1914. Filed Nov. 15, 1912. Serial No. 731,479.

Furnace Grate. W. M. Duncan, Alton, Ill. 1,088,773. Mar. 3, 1914. Filed July 18, 1912. Serial No. 710,140.

Mechanical Stoker. W. M. Duncan, Alton, Ill. 1,088,772. Mar. 3, 1914. Filed Apr. 8, 1912. Serial No. 689,214.

Smoke Burning Device. F. T. Farnum, Chicago, Ill. 1,087,358, Feb. 17, 1914. Filed May 31, 1913. Serial No. 770,820.

Mechanical Stoker. W. R. Wood, London, England. 1,087,155, Feb. 17, 1914. Filed Apr. 28, 1913. Serial No. 764,131.

Miner's Acetylene Lamp. U. Daubresse, Novinger, Mo. 1,087,645, Feb. 17, 1914. Filed Apr. 20, 1912. Serial No. 692,052.

Fuel Feeding Apparatus. C. D. Stevens, Muskegon, Mich. 1,087,333, Feb. 17, 1914. Filed Nov. 24, 1905. Serial No. 188,945.

Smoke Preventer. B. F. B Fairbrother, Keene, N. H. 1,088,136. Feb. 24, 1914. Filed Feb. 15, 1912. Serial No. 677,758.

Electric Locomotive. G. F. Perin, assignor to Jeffrey Mfg. Co., Columbus, Ohio. 1,086,396, Feb. 10, 1914. Filed May 15, 1911. Serial No. 627,241.

Grate Bar. G. E. Camp, assignor to International Heater Co., New York, N. Y. 1,089,317. Mar. 3, 1914. Filed Aug. 14, 1912. Serial No. 714,956.

Smoke-Consuming Device. D. Townsend, assignor to Cornell Economizer Co., Philadelphia, Penn. 1,088,639. Feb. 24, 1914. Filed Sept. 10, 1908. Serial No. 452,353.

Device for Signaling the Presence of Explosive Gas Mixtures in Fire Damp Mines. H. Neubauer, Siebleben, Germany. 1,088,611. Feb. 24, 1914. Filed Feb. 25, 1913. Serial No. 750,571.

CONSTRUCTION NEWS

Logan, W. Va.—The Island Creek Co., recently organized, has secured a lease on about 800 acres, and it is expected that development work will start in the next two or three weeks.

Andrew, Ill.—The Roberts & Schaffer Co. recently secured a contract for a Marcus patent coal tipple from the Cora Coal Co. to be installed at Andrew, Ill. This tipple will span five railroad tracks. A similar contract for a like tipple was secured from the Tecumseh Coal Mining Co. to be installed at Bicknell, Ind.

Wheeling, W. Va.—The Richland Coal Co. operating near Warwood, anticipates the building of 10 new houses intended

for the accommodation of employees within the next few days. Last year this firm was obliged to erect about 25 new houses. Expansion, however, has made necessary this additional number of dwellings.

Leavenworth, Kan.—The work of rebuilding the upper works of the Home mine will begin in the near future. The plant was partly destroyed by fire recently. A reorganization of the Home-Riverside Mining Co., also is to be effected. The mine has been operated by C. N. Fish and P. T. White, the latter of Cleveland, Ohio, as receivers for some time past.

Cornettsville, Ky.—The T. C. Seaman Coal Co., recently organized with headquarters at Winchester, Ky., plans the installation of a good-sized coal operation here on the Line Fork tract and the expenditure of several hundred thousand dollars in the development. A five-mile branch line of the Lexington & Eastern is necessary, construction to be started May 1.

Praise, Ky.—Track laying on the Carolina, Clinchfield & Ohio R.R. between Elkhorn City, Ky., and Dante, Va., is being rushed with all possible speed. It is said the work will be completed and train service inaugurated over the entire connection within 60 days. This line will form an important connection between the eastern Kentucky coal field and south Atlantic sea-coast cities.

Hazard, Ky.—The Hazard Town Coal Co., W. M. Jones, president, Williamsburg, Ky., is now doing the initial work on a coal development one mile from Hazard on the Lexington & Eastern R.R. It will ship from 50 to 75 tons per day from the start and make increases from time to time. Two short-line spur branches of the L. & E. will be necessary and the work has been begun.

Viper, Ky.—The Winfrey-Peters Coal Co. here will begin a large coal development on Mason's Creek, three miles from Viper, immediately. The development will consist of the building of a three-mile spur line of the Lexington & Eastern R.R. and the erection of three tipples, several hundred miners' houses, grade work, sawmilling, etc. The lumber necessary is to be manufactured on the ground. C. F. Winfrey is president and will manage the new work.

Dieder, Penn.—Excavation and foundation work incident to the erection of 124 additional coke ovens, and the rebuilding of the present 300 ovens of the Lehigh Coke Works, has been started by F. H. Clement & Co., with a force of about 250 men. It is expected that in a short time this force will be increased to about 500 men. The amount involved in the contract given this company is said to run into the hundreds of thousands of dollars, while the work will require at least two years for completion. When this contract is finished, the Lehigh Coke Co. intends to immediately start the construction of 124 other ovens.

NEW INCORPORATIONS

Seattle, Wash.—The Hyde Coal Co. is to increase its capital stock from $400,000 to $1,000,000 also to increase the number on the board of trustees from three to five.

Pikeville, Ky.—The T. N. Huffman Coal Co. has been organized with a capital stock of $15,000. The incorporators are T. N. Huffman, Hester A. Huffman and Mary C. Leslie.

Charleston, W. Va.—The Michigan & West Virginia Land and Mining Co. has been incorporated with a capital of $100,000, the purpose being to develop coal and mineral land in W. Va.

Birmingham, Ala.—The Canal Export Coal Co. has been organized with a capital stock of $300,000 to develop 400 acres of coal land. The intention is to mine about 1000 tons of coal daily.

Fairmont, W. Va.—The Delmar Coal Co. has been organized with a capital stock of $25,000. The incorporators are, A. H. Philips, of Grafton, W. Va., E. S. Philips, John F. Philips, Ralph A. Courtney and Clarence D. Robertson, of Fairmont, W. Va.

INDUSTRIAL NEWS

Mt. Pulaski, Ill.—The Mt. Pulaski Colliery Co.'s mine here is to be sold under a court order on May 5.

Terre Haute, Ind.—The regular quarterly meeting of the Indiana Fireboss Association was held on Apr. 8, with about 85 per cent. of the membership present.

Berlin, Germany—The Krupp Co. recently purchased the exclusive right to work 60 coalfields on the estate of the Duke of Troy near Duelmen, Austria. The price paid is said to exceed $5,000,000.

Youngstown, Ohio—The 80 new Koppers byproduct ovens of the Republic Iron & Steel Co. will be put in operation for the first time in a few days. About 200 unskilled workmen are being employed.

Greenview, Ill.—Alfred Svenson, a former mine manager and hoisting enginner, is conducting drilling operations with a view to opening a small country mine near this place. He is not, however, sure of finding coal.

Connellsville, Penn.—It has been announced that the Consolidation Coal Co. interests in Sommerset County by a contract entered into recently has received orders for the mining during 1914 of 1,140,000 tons of coal, principally for export.

Columbus, Ohio—The Hocking Valley Ry. Co. and the Sunday Creek Co. have asked the U. S. supreme court to review the recent decision of the federal court assessing a fine of $42,000 against the Hocking Valley Ry. Co. for accepting unsecured notes in payment of prepaid freight charges.

Birmingham, Ala.—There is considerable talk here at the present time of a possible merger of the Woodward Iron Co., the Republic Iron & Steel Co., (southern properties), the Sloss-Sheffield Steel & Iron Co. and the Gulf States Steel Co. The heads of these various firms will not, however, discuss the matter.

Chattanooga, Tenn.—By an amendment to its charter the John R. Barnes Coal Co. changes its name to the Kentucky-Tennessee Coal Co., and increases its capital stock from $50,000 to $100,000. George T. White, H. B. Bonney, W. L. Lawton, J. R. Barnes and W. B. Carvin are the incorporators who filed the amendment.

Galveston, Texas—The Texas City Transportation Co., on Apr. 15, filed suit in the Unitel States District Court, against the Davis Coal & Coke Co., of West Virginia asking damages to the amount of $40,176.90 on the ground of failure to fulfill a contract for the delivery of 180,000 tons of coal to the plaintiff at the rate of 60,000 tons per year.

Chicago, Ill.—The newly formed Chicago section of the American Institute of Mining Engineers held its first annual meeting and dinner on the evening of Apr. 14, at the Sherman House. The officers elected were: Chairman, Robert W. Hunt; Vice-Chairman, J. C. Ede; Secretary-Treasurer, H. W. Nichols; Executive-Committee, F. K. Copeland and G. M. Davidson.

Springfield, Ill.—On petition of the Sangamon Loan & Trust Co., the Williamsville Coal Co. located at Selbytown, was recently placed in the hands of a receiver on failure to provide for the payment of $40,000 worth of bonds. H. J. Linkin was appointed receiver for the company and his bond was placed at $10,000.

Peoria, Ill.—Thomas Fox, Neil Groat, George Green, and Willis McGrew, four Springfield miners, recently purchased the Yocum mine near Lewistown, and will take possession shortly. They plan to place this property in such condition as to increase the output and reduce the cost of operation. Coal will be simply produced for the local market.

Louisville, Ky.—During the two weeks ending Apr. 18, the Monongahela River Consolidated Coal & Coke Co. shipped approximately 100,000 tons through the local harbor for New Orleans, leaving coal enough for a month or so in the local harbor, with little in sight in the way of shipments. G. W. Shaw, traffic manager for the company from Louisville to New Orleans, has been in New Orleans and at the various cities between there and Louisville where the company has branches.

Clarksburgh, W. Va.—Judge A. G. Dayton in the Federal District Court on Apr. 17, imposed sentences on the striking miners of Colliers, W. Va., for violation of the injunction against interference with employees of the West Virginia & Pittsburgh Coal Co. The men sentenced were guilty of preventing a party of 18 strike breakers from going to work. The sentences imposed ranged from small fines to six months imprisonment.

Bluefield, W. Va.—A committee representing the South Carolina Cotton Manufacturers Association recently placed contracts for 350,000 tons of coal with the Blackwood Coal & Coke Co., the Stonega Coal & Coke Co., the Virginia Iron, Coal & Coke Co., and the Black Diamond Coal Co. The competition for the transportation of the coal from the fields of Virginia and Tennessee will fall to the Southern and Chesapeake & Ohio Ry. companies.

Coal Trade Reviews

General Review

Anthracite active but developing signs of weakness. Soft coal restricted without enough demand to absorb the heavily curtailed production. Business confined to negotiations on new contracts. Poor showing in the Lake trade.

Although the anthracite trade is generally active in all departments, contradictions and crosscurrents are beginning to develop uncertainties in the situation. On the one hand it is noted that mines are working up to full capacity, while most of the companies are refusing to accept further business for April delivery, and it is clear that many April orders will be carried over into the next month, particularly on certain short sizes. On the other hand, careful observers point to distinct indications of weakness in basic conditions, such as less surplus orders than customary during the opening month, a light demand in the lake trade, and a request that shipments be discontinued because of lack of further storage room—a most unusual condition in April. In fact, it is generally agreed that the anthracite trade is beginning to feel the effects of the pressure under which bituminous has been laboring for several months.

The soft-coal business is characterized by an entire absence of any demand while the market is dull and restricted, with business confined to small lots. Consignment coal is still coming in, creating a soft condition in the spot market which the operators are making desperate efforts to maintain in order to avoid a decline in quotations on contract business. Interest is concentrated almost entirely upon this latter phase of the situation, and some agencies that have already lost business by holding out for high figures are now showing a disposition to make concessions. It is generally felt that the bottom of the market has been reached, but there is much uncertainty as to how long it will continue at the low level.

Production in the Pittsburgh district is larger than there is any demand for. Business in Ohio is confined entirely to negotiations on contracts for the new year, there being neither any production or apparent demand for coal, the West Virginia product filling what meager call develops. Indications for the lake business are poor so far, and the first half of the season, at any rate, will witness a light movement. The naval maneuvering out of Hampton Roads and the demonstration against Mexico has resulted in a heavy loading at some of the Atlantic Coast ports, which has been supplemented by a fair movement in the customary coastwise and foreign trade. There are indications of some improvement in the nonunion fields, as a result of the more or less complete cessation of mining in the organized districts. However, the large consumers are standing out determinedly for lower prices, and not much business is being definitely closed.

A few isolated mines are reported working in the Middle Western field, but the demand is so light that even these are compelled to operate under restricted capacity. It is a situation of no coal, and likewise no demand.

EASTERN MARKET

BOSTON

Concessions on Pocahontas and New River for season delivery are slight, but yet have an effect on the trade. Spot market continues quiet. Distributors who guaranteed season prices are apprehensive over the amount of "market coal" coming forward. Anthracite shipments heavy, but stove, broken and screenings are short.

Bituminous—A few more of the mill contracts have been closed the past week, generally at prices that net close to the $2.85 figure for Pocahontas and New River at Hampton Roads. The "cuts" that have been made on season business so far have been light, but at the same time even slight concessions have their effect on the market. Part of the disposition to shade prices is due to the determination of certain of the agencies to hold business they acquired last year. Some of the contract business offering in February and March was lost to merchants who were in better position to name attractive water rates.

The spot market is still easy and with practically no new developments. Cargoes continue to arrive on consignment and low prices therefore prevail at the distributing points. A large volume of season business was closed early at $3.80@3.90 f.o.b. Boston, for instance, with a clause guaranteeing the price against a decline, and if spot coal continues to be sold down to $3.63@3.73 it will be interesting to see whether the distributors who made the early contracts will be obliged to scale down their prices. Were it not for these contracts the spot price would probably be put low enough to discourage shipments "on the market."

The market for the Pennsylvania coals is narrow and restricted. The coastwise trade just now is pretty well confined to small lots loading in conjunction with anthracite, and this almost entirely from Philadelphia. New York consignments are mostly to Long Island Sound and the demand there is light. All-rail trade shows no improvement. The staple varieties are having fair business for so dull a season, but most of the operators are clamoring for orders.

Anthracite—Cargoes are coming forward freely and some of the dealers here are rapidly getting to the point where they will have to call a halt on shipments. The retail demand is still exceptional, but a few days of warm weather will put it on a normal basis. Stove size is hard to get and screenings and broken are also in short supply.

Bituminous prices are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$0.95@ 1.50	$1.25@ 1.65	$1.67@ 1.77	
New York*	2.20@ 2.75	2.50@ 2.90	2.92@ 3.02	
Philadelphia*	2.50@ 3.05	2.80@ 3.20	3.22@ 3.32	
Baltimore*	.....	.....	2.85@ 2.95	
Hampton Roads*	.....	.....	.....	$2.80@ 2.85
Boston†	.....	.....	.....	3.63@ 3.78
Providence†	.....	.....	.....	3.55@ 3.78

* F.o.b. †On cars.

NEW YORK

Increased activity in anthracite at close of the month. A heavy demand in the line trade. Believed the low point in bituminous has been reached but duration of existing conditions indeterminate. Scarcely any prompt market quotable.

Anthracite—While locally the demand for anthracite coal, particularly the prepared sizes, has not been heavy, the general situation throughout the country has improved materially during the past week or ten days and from the operating end the business is in excellent condition. Contracts are taking full production of broken coal. The general market is absorbing at full circular all of the egg and stove coal, the latter being particularly short. Chestnut is inclined to be dull and inactive and all of the small sizes are in short supply . Some of the companies have already refused to accept further orders on stove coal and have at the same time notified their customers they will not agree to accept any further orders for delivery at the April price. The line demand is heavy and most of the individual coal is being supplied to that trade. The heavy demand for the higher grade steam sizes is subject to comment. While the poorer qualities are available at moderate prices they are moving promptly and with little trouble.

There is a tendency on the part of many of the consumers to shift to bituminous coal or to a mixture of bituminous and No. 2 or No. 3 buckwheat. This mixture is becoming more popular with a large part of the smaller consuming trade while the larger concerns are changing gradually to bituminous entirely.

The dealers around New York have made a set price for April and May and are finding business somewhat dull for April, but appear to be well booked up for May deliveries. It is anticipated that the movement of coal will be heavy for the next month or two at least.

The New York market is now quotable as follows:

	Upper Ports		Lower Ports	
	Circular	Individual	Circular	Individual
Broken	$4.60	$4.60	$4.55	$4.55
Egg	4.85	4.75@4.85	4.80	4.70@4.80
Stove	4.85	4.85	4.80	4.70@4.80
Chestnut	5.10	5.10	5.05	4.95@5.05
Pea	3.55	3.50@3.60	3.50	3.35@3.50
Buckwheat	2.80	2.80@2.90	2.50@2.75	2.35@2.80
Rice	2.30	2.30@2.40	2.00@2.30	1.80@2.25
Barley	1.80	1.80	1.70	1.40@1.75

Bituminous—There has been little or no change in the market on bituminous coal during the past week in spite of the large number of mines idle in the Central Pennsylvania field. There are still many shippers embargoed to Port Reading on account of an over-accumulation. Considerable of this coal is of the cheaper grade from West Virginia, but at the same time some of it comes from the union field, now on suspension, and some from the Pittsburgh district. This is due no doubt to the desire of the shippers to prepare themselves with an extra stock of coal in order to take care of their trade during the suspension. Consumers are well fortified with stocks equivalent to at least four weeks supply and at the same time it is most difficult to make sales on any grade of coal at any price.

While the present situation is probably the most tense we will have to consider for the coming year, it is doubtful if any material increase in demand will develop for the next week or two at least and in any event any increase will likely be very gradual.

It is estimated that about 30% of a normal tonnage is coming from the Central Pennsylvania district, but even those operators still working are finding it most difficult to keep their mines operating on account of the lack of orders. Producers of the better grades are inclined, however, to hold their coal at a moderate price or close down. Coal in the hands of shippers now at the piers and especially the poorer grades is being offered at extremely low figures ranging from $2.10 f.o.b., up. In addition to this there are several loaded cargoes of poor coal offering at very low prices, but the nominal market continues as follows: West Virginia steam, $2.50@2.60; fair grades Pennsylvania, $2.60@2.70; good grades of Pennsylvania, $2.70@2.80; best Miller Pennsylvania, $3.10@3.15; Georges Creek, $3.15@3.25.

PHILADELPHIA

No apparent falling off in demand for anthracite, and trade looks favorable for the next month or six weeks. Many orders and deliveries behind. Conditions in bituminous show no improvement. Volume of business and prices about the same.

Anthracite—The closing days of the first month of the new anthracite season, find the trade in a favorable position, and it is not expected that there will be any radical change for the next six weeks. This, of course, applies to the prepared sizes. Already the market for pea coal, influenced by the summer weather, has shown a marked inclination to sag, and it is understood that the surplus is being put into stock; No. 1 buckwheat and rice are still finding a ready market, and with the one exception, all sizes are moving off on orders.

Considerable dissatisfaction is always expressed during April, owing to the inability of the producing companies to supply all the demand at the lowest season's prices. The best distribution possible is made, orders being filled consecutively as entered, but with the demand centered on one or two sizes, it is not possible to satisfy any one. As is always the case, there is a large influx of orders during the closing days of the month, those having the space to store, placing orders with the expectation of saving the ten cents per ton.

	Circular	Individual
Broken	$4.25	$4.35
Egg	4.50	4.50
Stove	4.50	4.60 @ 4.70
Chestnut	4.75	4.75
Pea	3.25	

Bituminous—More interest is manifested in the bituminous market. Notwithstanding that fully 75 to 80% of the bituminous operations have suspended the trade does not seem to reflect any abnormal condition. It is evident that the consumers have ample stocks, and are not fearful of being unable to replenish them at other than normal market figures. The general business may be characterized as dull. A slightly better demand was noted early in the week, but the prices realized were those of a week or two past.

BALTIMORE

Shipments on contract practically the only business. Price list steady. Anthracite retailers announce spring and summer prices with addition of Pennsylvania state tax.

The trade as a whole is paying little or no attention to the light spot business now being negotiated at unsatisfactory prices, and instead are bending their energies to make the most out of their contracts. The movement on contract is moderately good when general industrial conditions are considered. Considerable coal is moving to Gulf ports, and the shipments to New England are on the increase. Midsummer is expected to find about a normal movement in that direction.

Meanwhile prices remain fairly steady. Spot coals are being held close to the general basis of contracts. West Virginia fuels are the dullest, three-quarter is selling at the mines at from 80 to 85c. and slack as low as 70 or 75c. Steam fuels from West Virginia are holding well at from 90c. to $1, low grade Pennsylvania line coals at from $1 to $1.15 with the choicer grades around $1.25, and the best at from $1.35 to $1.40.

The retail anthracite circular was announced the past week. It remains the same as last spring with the exception of an addition of 10c. per ton on all grades to cover the assessment of the Pennsylvania tax. The low figure, 40c. off the old fall schedule, will hold until May 31, and will then advance 10c. each month during June, July, August, September and October.

CENTRAL STATES

PITTSBURGH, PENN.

Pittsburgh district mines more than full handed. Production in excess of requirements. Business so light, market prices have scarcely developed. Connellsville coke stagnant, with consumption decreasing.

Bituminous—Miners apparently did not understand conditions as to referendum vote on wage scale and many refused to work at first, there being only about 10 mines in Pittsburgh district operating at beginning of last week. But they have since been returning and there were enough men this week to do all work required, which is not much, because of the large stocks and lake season not having opened. Pittsburgh district is this week producing about 40% of the full tonnage. It is understood that counting of referendum vote in this district is completed, but formal announcement has not been made at this writing. A conference will then be arranged for the usual adjustment of various local matters and this will probably be accomplished by end of month.

There has been little demand for coal and sales have been too light to establish a market. It is probable that concessions could be secured in some cases from the regular prices which continue as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district. There have been practically no negotiations for lake coal and shipments by the regular interests are not likely to be of any volume for several weeks.

Connellsville Coke—The market has been absolutely stagnant. Some coke is being released through the blowing out of furnaces but operators doubtless intend to restrict production accordingly, for if any coke were forced on the market, prices would undoubtedly suffer. The market is largely nominal, as follows: Prompt furnace, $1.90@1.95; contract furnace, $2; prompt foundry, $2.40@2.50; contract foundry, $2.40@2.50, per ton at ovens.

BUFFALO

No improvement in bituminous market. Slow mining is reducing surplus materially but will take some time yet to affect prices. Coke inactive, but bottom prices appear to have been reached. Anthracite easy when it should be rushing.

Bituminous—There is still some coal on track here and elsewhere, but the congestion is slowly disappearing. Dealers say that it will take till May 15 at least to clean up the supply so that consumers will come back into the market as they are much overstocked. Consumption appears to be slower than a year ago and shows no disposition to increase. As a rule the Buffalo trade is paying little attention to the open market. They all have contracts and regular orders as a rule and it is enough for the present to look after them. The difficulty comes from some misguided mine owners dumping coal on this market after failing to sell it elsewhere. It is seldom possible to sell such consignment coal at a profit. The Allegheny Valley miners are practically all idle and they are not expected to resume work again till May. There is no difficulty as a rule, but the men will seldom work when there is a rate agreement pending. This is quite satisfactory to the operators, who say that the prospect is good for resumption sometime next month on exactly old conditions. A good increase in consumption would insure a paying trade, but such is hardly anticipated.

The prices of bituminous are about as weak as they can be, but quotations remain on the former basis of $2.80 for Pittsburgh lump, $2.70 for three-quarter, $2.55 for mine-run and $2.25 for slack. The demand for slack is much better than for sizes, but it will ease off as soon as there is more three-quarter made for the lake trade.

The first sailing from this port, on Apr. 16, increased the activity at the docks. The price for three-quarter delivered

on board is $2.90, the same as last year. Nearly all the coal used in that trade is three-quarter.

Coke—There is little demand beyond the regular movement to the furnaces, but the standard ovens refuse to reduce their prices any further. It is said that where a reduction is made it is always on coke that is not of the best. Quotations remain on the basis of $4.50 for best 72-hr. Connellsville foundry.

Anthracite—The trade is good, though April sales will be much smaller than usual. Shippers are not troubled about it, as the prices will be higher next month. Before the end of April they have usually received two or three times the amount of orders that they could fill but this is not the case now and some of them will be practically even with their orders by the opening of May.

Several lake steamers have gone to Ohio ports to load coal for the upper lakes and one or two cargoes will go out soon. The start is slow and it may be sometime before the Sault passage is open. There is never any life to the lake trade till iron ore moves.

COLUMBUS

Attention of industry in Ohio concentrated on the coming conference of operators and miners. Little demand for either domestic or steam grades. All mines are still closed.

The coal trade during the past week was quiet in every way. As none of the mines are in operation the production was nil. Operators and jobbers report few inquiries and it appears that there would be little demand at this time even if the mines were in operation.

The coming lake trade is attracting some attention, although the prospects are not bright. While navigation is practically open, no coal will be landed on the docks at the Northwest prior to May 1 when the tax listing is done in the states of Wisconsin and Minnesota. There is still considerable tonnage on the docks and as a result not a great deal of coal will be shipped early in the season. Even were the mines running there would not be much activity in the lake trade before June 1.

Steam demand is light as most of the steam users have a supply on hand for 60 days. Railroads are not using much coal since many of their trains have been discontinued. Domestic trade is about a thing of the past. Dealers have ample stocks for the time being and will not be in the market before the stocking-up period. Some demand is reported for Pocahontas and other fancy grades of domestic fuel. While this is the time for many steam contracts to expire, little is being done toward renewal pending a settlement of the wage agreement. Railroad contracts will be up as soon as the basis of mining is settled.

What quotations are being made in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.45@$1.35		$1.50@$1.40	$1.40@$1.35
¾-inch	1.30@ 1.25	$1.20@$1.15	1.35@ 1.30	1.30@ 1.25
Nut	1.25@ 1.20		1.30@ 1.25	1.25@ 1.20
Mine-run	1.15@ 1.10	1.10@ 1.05	1.15@ 1.10	1.15@ 1.10
Nut, pea and slack	0.90@ 0.85		0.90@ 0.85	0.80@ 0.75
Coarse slack	0.80@ 0.75	1.00@ 0.75	0.80@ 0.75	0.70@ 0.65

CLEVELAND

Sales for shipment are being taken at prices hardly better than those offered for spot coal. The spot market has cleaned up. Shipping has started to Lake Michigan, but Lake Superior navigation is still closed. Pocahontas operators have pretty well sold up their May and June output of screened coal.

The lowest prices of the year were made last week to clean up soft coal. Youghiogheny slack was sold at $1.55 and three-quarter Richland, No. 8, brought $1.85. Fairmount coarse coals were sold at around $1.95. Very little coal is being carried over the week end, but what is enroute may change the situation for a day or two.

Sales of Fairmount gas for shipment were made the latter part of the week at $1.90 Cleveland for lump and $1.80 Cleveland for slack. The orders were not large, but indicate the market is beginning to rid itself of storage coal. It will be another ten days before the true strength of the market can be judged.

Rumors that No. 8 mine-run has been sold on contract at $1 f.o.b. mines were quite common the last few days. The general tone of the market is toward slightly lower prices on contract coal during 1914 than last year. Little contracting has been done in Ohio coals because of the unsettled labor condition. Those who have been closely following the market report the larger buyers are not in need of as much coal as last year and estimate a lake movement of 21,000,000 to 22,000,000 tons of bituminous coal as compared with 28,000,000 tons in 1913.

Coal has been loaded at all the lake shipping ports during the last week and a few vessels have sailed, but the traffic will continue light the rest of the month. The Straits of Mackinac have been opened by fish tugs which did not find the ice bothersome. Three boats arrived at Detroit, Mich., Saturday with coal for the Algoma Steel Co. at Sault Ste Marie, Ont., but did not try to proceed until Sunday. The heavy ice in Whitefish Bay at the entrance to Lake Superior is so thick and the extent so great that none of the ships will be able to get through before Apr. 25.

All doubt as to freight rates on the lakes was removed last week when the C. Reiss Coal Co. chartered vessel capacity to transport 2,000,000 tons of bituminous coal to ports on Lakes Michigan and Superior at 30c. It has been customary for the Reiss company to pay less than the Milwaukee rate for coal going to Sheboygan, but the rates this year are too low for a differential. The shippers who were talking a lower rate to Lake Superior ports gave up the idea when the Reiss rate was announced.

Prices of coal for shipment are as follows:

	Pocahontas	Fairmount
Lump	$2.95	$1.90@$1.95
Egg	2.95	
Mine run	2.60	
Slack	2.60	1.80@ 1.85

CINCINNATI

Refusal of West Virginia operators to increase wage rate causes alarm in the local market. Dealers have enough supplies on hand to last thirty days. Trade unusually quiet and dull.

Local dealers are greatly concerned over the action of the operators of West Virginia in not only refusing to meet the demand of the miners for a 10% increase, but in seeking to have the men accept a decrease. This action of the operators was brought out at the joint conference in session at Charleston, W. Va., last week. The operators declare they have reached a point where it is better to shut down than to operate at a loss, and figures are quoted showing that since 1902 advances of 40% have been made in the prices of pick mining while the increase in the selling price has been only 8%.

Most of the coal sold in this market is West Virginia mined and the local dealers are fearful that the operators and miners will not come to an amicable understanding. These dealers state they have enough coal on hand to last probably 30 or 60 days if there be no spirited demand, which they say is hardly likely. There has been no perceptible change in the local market during the past week. Trade has been unusually quiet and dull with prices holding firm.

TOLEDO

Shutdown of the mines has little effect in the local market. West Virginia grades supplying present demand, which is light. Large tonnages at the local docks for lake shipment.

The feature of the present market is the exceedingly light demand for steam coal. Most of the larger plants are sufficiently stocked to meet immediate requirements. With the cessation of work in the Ohio mines, the trade is finding no difficulty in meeting the meager demand with coal from West Virginia. A great many of the Toledo operators are reporting a fair number of inquiries for contracts.

The docks at Toledo are filled with coal awaiting lake shipment. The first boat for Duluth cleared Wednesday having some surplus stock from the Ohio and Pennsylvania fields, but mostly from the West Virginia regions. Because of the comparatively lower rate in lake shipping, many of the shippers are taking advantage of immediate transportation to the upper lake ports. There is a heavy demand for Pocahontas. One of the largest wholesalers reported having already contracted for all the available Pocahontas up to Aug. 1. Prices on available Ohio and Pennsylvania stock have not changed.

DETROIT

Improving tendency but consignment coal still difficult to move. Some activity in contracting. Anthracite in good demand and coming in slowly.

Bituminous—While there are some indications of improvement, it is still a fact that jobbers are busy disposing of coal coming in on consignment, the coarse sizes being particularly hard to move, due to the unusually heavy demand for slack. Consumers are now showing a disposition to cover on contracts, a number of which have been recently closed at prices said to be 5 and occasionally even 10c. a ton above last year's level. On the other hand, some unusually low figures are being quoted on track coal, Hocking lump being offered down to $1.10, as compared with a circular price of $1.75. On the Pocahontas grade the circular is being generally maintained.

Anthracite—Hard coal continues moderately active and strong, particularly on stove and chestnut sizes, which were

practically cleaned up on Apr. 1. There has also been some anxiety on the part of the trade, due to the slow arrivals.

Coke—Coke is the most satisfactory branch of the local trade, a large tonage being moved with comparatively little effort. Connellsville foundry is quoted at $3, with Semet Solvay at $3.25 and gas house $2.90.

HAMPTON ROADS

Fair shipments for the week. Government loadings heavy. No change in prices. Some small movement of high volatile.

Coal shipments from Hampton Roads piers have been fair some large cargoes moving both coastwise and foreign. Government loadings have also been fairly heavy. While there has been no demand for high volatile coals for spot movement there have been some shipments made during the week for New England. No doubt this coal has moved on contract.

Foreign cargoes have gone to Kingston, Santiago, Daker, Coronel, Valparaiso, Naples, Rio de Janeiro, Genoa, Para, Venice, Manos and Canal Zone.

The largest single cargo of the week went into the U. S. Collier "Nereus" which took approximately 12,500 tons. Prices on all grades remain the same as they have been for some time. On account of light demand on coastwise shipments several schooners have been compelled to lay idle in the Roads waiting for charter.

LOUISVILLE

Effects of suspension being felt and some improvement is noted. Steam sizes becoming short. Cuts in new contracts.

Suspension of mining operations in the union fields has tended to improve the outlook in this market. Some improvement is noted, especially in the Eeastern Kentucky and East Tennessee coals, attributed in part to the labor troubles and also to the opening of the shipping season for coal westbound from Lake Erie ports. Though the first of April found heavy stocks, May is expected to see large quantities of these depleted.

The steam market continues slow, some dealers finding it necessary to shade prices sharply in order to dispose of such grades on the open market. One agency for a group of Western Kentucky mines has found it necessary to stock up heavily on lump coal in order to get enough nut and slack to fill its steam orders although this is not usual as yet. It is possible that many of the new contracts for steam coal will have to be at a reduced figure. Large consumers are demanding reductions and numbers of large contracts have been renewed at 5c. and even 10c. under the price of a year ago; on the other hand many important contracts have been closed at the same level.

It is necessary frequently to make concessions in both domestic and steam coal to secure a regular amount of business in Louisville. The advent of natural gas has not as yet had any apparent effect on the coal market, though the retail dealers are disturbed as to what may happen next fall and winter. Prices are quoted at from 50c. for pea and slack and 75c. for nut and slack in the Western Kentucky fields to from 65 to 75c. for the best and 40 to 50c. for inferior grades of nut and slack in the Eastern Kentucky fields. Eastern Kentucky block coal to the retail trade is quoted at from $1.30 to $1.60 with egg at from $1 to $1.30, all f.o.b. the mines.

SOUTHERN AND MIDDLE-WESTERN

BIRMINGHAM

Dealers delaying placing orders for lump coal. Steam grades still quiet. Tests of Alabama fuels being made in Cuba. Furnace and foundry coke quiet, and blacksmith normal.

The dealers are still putting off booking lump coal for summer and fall shipment, as has been the usual custom, waiting to see if the operators intend to lower prices as an incentive for larger orders. But it seems to be the opinion that the producers are going to hold to original quotations, as they feel that to make concessions would set a precedent that would have to be repeated every year. Though some few contracts are being let on steam coal, the market is still quiet, and no improvement is looked for until the brick and oil manufacturers contract for their supply, which runs through the summer and fall. However, prices on steam coal remain firm.

One Alabama operator has shipped a large consignment of coal to Cuba, by a specially charted steamer, having made arrangements with several Cuban manufacturers to make an exhaustive test of the coal. Should it prove satisfactory, it will mean that a large tonnage will be contracted for. Both furnace and foundry coke are quiet, with practically no sales larger than carload lots. Blacksmith coal is about normal, with no change in price. There is practically no pig iron being sold, though shipments are being made in the normal tonnage; production is not being curtailed to any extent, and no immediate relief is looked for. The car supply is plentiful.

NEW ORLEANS

Anthracite commanding a slight premium, but weakness in other grades is pronounced. Decreases in fuel oil prices affect the market. Marine demand above normal. Alabama waterways soon to be ready for perennial navigation.

While anthracite is a trifle higher than last year, all grades of bituminous are selling at a decidedly lower level. The mines in Alabama are operating at 50% capacity and there are prospects of further decreases. Much interest is being taken in the contract soon to be let by the American Sugar Refining Co. as it will give an idea as to just how low different companies are prepared to go.

Due to the activity in shipping, as well as the frequent visits of American war vessels stationed in Mexican waters, the demand for coal has been brisk along the harbor front. This has been offset, however, by quietness in the interior, due to the falling price of fuel oil.

High water in the Alabama river system has permitted the transportation of considerable coal by the water route to Mobile and New Orleans. Government engineers, in charge of the work at locks Nos. 2 and 3 on the Tombigbee River, state that the work will be completed earlier than had been expected and perennial navigation will then be assured. Work is being pushed, night and day shifts and Sundays and holidays.

In laying in stocks for this summer, all dealers are taking into consideration the probable increase in the requirements of the bunker trade, following the early opening of the Panama Canal. Several new steamship lines, having this port as their terminus, will begin operation at that time, which will mean that their entire coal supply will come from this port.

ST. LOUIS

Production practically cut off altogether but no buyers are to be found for what small tonnages are offering.

There is no coal to offer, at least, very little, and with no buyers for even this. At no time was the situation so completely dead as it is at present. A few buyers are showing a little anxiety over the future prospect for screenings and the smaller sizes of coal. Buyers who pay cash for this kind of coal can get it at their own figure, while those asking 30 to 60 days can seldom get the coal.

For the most part the operating mines in the Standard field, that is the fifth and ninth districts are coöperative and must have their money on the fifteenth and thirtieth of every month for coal shipped in the preceding two weeks; hence they must sell to cash customers who consequently, are able to buy the coal at their own figure. Coöperative coal mining means working for less than the regular scale and putting the operator who is paying the scale at a disadvantage.

Standard 2-in. lump coal has been sold as low as 85c., while the screenings are bringing from 75 to 80c. In the Carterville-Franklin County field a few mines are working in isolated places, but even their limit seems to be about two days a week. One Chicago operator, with mines at Marion, Ill., is offering lump and egg at $1.05 the mines, and a Franklin County producer at West Frankfort is a close second. The better grades of coal from Williamson and Franklin Counties, lump and egg, are bringing from $1.25 to $1.45, while No. 1 nut is in some demand. Carterville screenings are good for about 80 to 90c., while in some cases 2-in. screenings are bringing 95c. and $1. A great many operators seem to figure that there will be no increase in the scale, and are contracting accordingly.

There is a fair tonnage of anthracite moving in, but nothing in the way of coke, and very little smokeless.

The market at the closing of the month was:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard	Sparta
2-in. lump	.....	.....	.....	$0.90 @ 1.00	$1.15
3-in. lump	.....	.....	$1.35	.....	.....
6-in. lump	$1.35 @ 1.50	.....	1.50	1.10 @ 1.25	1.35
Lump and egg	1.85 @ 2.15	$2.25	.....	.....	1.15

FOREIGN MARKETS

GREAT BRITAIN

Apr. 9—The market is quiet and owing to the holiday influence, business is on a small scale. Quotations are approximately as follows:

Best Welsh steam	$4.50	Best Monmouthshires	$4.11
Best seconds	4.38	Seconds	3.96
Seconds	4.23	Best Cardiff smalls	2.82
Best dry coals	4.20	Seconds	2.70

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are net f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days.

Coke is quoted at: Special foundry, $6.24; good foundry, $5.28@5.52; furnace, $4.32@4.56.

PRODUCTION AND TRANSPORTATION STATISTICS

NORFOLK & WESTERN RY.

The following is a statement of coal handled by the N. & W. Ry. during February of the current year in short tons.

Pocahontas Field	942,477
Tug River District	204,074
Thacker District	198,228
Kenova District	71,401
Clinch Valley District	152,769
Other N. & W., Territory	3,694
Total N. & W. Fields	1,572,643
Williamson & Pond Creek R.R.	26,314
All other railroads	67,518
Grand total	1,666,475

Following is a comparative statement of the N. & W. tonnage for March, 1913 and 14:

	Shipped		Tipple		Total	
Field	1914	1913	1914	1913	1914	1913
Pocahontas.	1,055,756	1,003,352	18,137	16,363	1,073,893	1,019,715
Tug River..	243,546	184,658	2,944	3,169	246,490	187,827
Thacker....	266,579	238,340	8,207	8,978	274,786	247,318
Kenova....	79,331	59,345	9,285	7,470	88,616	66,815
Totals...	1,645,212	1,485,695	38,573	35,980	1,683,785	1,521,675

Shipments of coke, entirely from the Pocahontas field, were 71,620 tons in March of this year as compared with 116,219 last year.

IMPORTS AND EXPORTS

The following is a comparative statement of imports and exports in the United States for January, 1912-13-14, and for the seven months ending January, 1912-13-14, in long tons:

	7 Months			January	
Imports from:	1912	1913	1914	1913	1914
United Kingdom	5,644	7,218	4,913	1,168	2,120
Canada	513,569	843,962	579,071	109,520	84,092
Japan	7,057	30,004	74,306	5,494	11,385

COAL FREIGHT DECISIONS

I. C. C. No. 5558—Hughes Creek Coal Co., and Kelly's Creek Colliery Co. (No. 5558 Sub.—No. 1) vs. Kanawha & Michigan Ry. Co.

1. Complainants' request for through routes and joint rates between stations on the Kanawha & Michigan Railway and its branches and the points specified in the complaint in eastern and southeastern territory on the lines of the Chesapeake & Ohio and its connections should be granted. As reasonable rates for these routes defendants should apply rates not in excess of those now applying to these destinations for shipments from the mines on the Chesapeake & Ohio. The factor of the two-line haul in the routes sought by complainants is negligible, since the switching connection between the Kanawha & Michigan and the Chesapeake & Ohio is simple, and the average haul to destination is more than 500 miles. Sheridan Chamber of Commerce v. C., B. & Q. R.R. Co., 26 I. C. C., 638, 647-649; Investigation of Alleged Unreasonable Rates on Meats, 23 I. C. C., 656,661. The policy of the Chesapeake & Ohio to restrict the movement of coal on its line confined solely to coal originating on its own line held not to be justified.

2. Complainants' request for a through route and joint rate to the Cincinnati switching territory over the Kanawha & Michigan and the Chesapeake & Ohio and its connections should not be granted. Such a route would give the Kanawha & Michigan a short haul of very much less than the entire length of its line.

3. The fact that the defendants have established through routes and joint rates from Chesapeake & Ohio mines to Kanawha & Michigan destinations while refusing complainants the through routes and joint rates sought does not constitute unlawful discrimination when viewed in the light of the principles applied in Coke Producers Asso. of Connellsville Region v. B. & O. R.R. Co., 27 I. C. C., 125, and the cases there cited, which hold a test of discrimination to be the ability of one of the carriers participating in the two through routes to put an end to the discrimination by its own act.

4. The charge that since the Chesapeake & Ohio and the Kanawha & Michigan are practically one road it is unjustly discriminatory for them to deny the Kanawha & Michigan mines access to markets which have been made available for Chesapeake & Ohio mines held not to be established. For the purposes in question no such identity between the two roads as complainants assert has been proven.

COAL SECURITIES

The following table gives the range of various active coal securities during the week ending Apr. 18.

	Week's Range			Year's Range

DIVIDENDS

Reading Co.—Regular quarterly of 1% on the first preferred payable June 11 to holders of record May 26.

Burns Bros.—Regular quarterly No. 3 on the common of $1.25 payable May 15 to holders of record May 1 and regular quarterly No. 5 on the preferred of $1.75 payable May 1 to holders of record Apr. 15.

Consolidation Coal—Regular quarterly of 1½% payable Apr. 30 to holders of record Apr. 25.

Pacific Coast—Regular quarterly on the first preferred of 1¼% and 1½% on the second preferred; and common, all payable May 1 to holders of record Apr. 25 to May 1.

Financial Department

Nova Scotia Steel & Coal Co.

President Robt. E. Harris reports for the year ended Dec. 31, 1913 as follows:

The profits for the year were $1,255,954, as compared with $1,000,610 for 1912. Dividends at the rate of 8% on the preferred and 6% on the common stock have been paid quarterly.

The sum of $32,659 has been applied to the sinking fund for retiring bonds, $70,185 has been added to the reserve funds, and $107,682, expended for improvements and betterments, has been written off. The aggregate of these sums is $210,527, and is considerably in excess of the amount deemed necessary to provide for depreciation.

During the year $2,000,000 of debenture stock was sold and the proceeds applied in payment of the amounts expended in 1912 and 1913 on capital account. The amount charged to capital account in respect to the expenditure of the past year is $1,158,462.

The Eastern Car Co. (whose entire issued common stock is held by your company) has been continuously engaged since September in the manufacture of cars, and its operations indicate that it will prove a valuable asset to our shareholders.

Work on the new Jubilee shaft at Sydney Mines has been carried on throughout the year, and it is expected that this colliery will be fully equipped early in the year 1915. An additional open-hearth steel furnace has been erected at Sydney Mines. A large amount of work has been done in further developing our submarine iron ore areas at Wabana and many additions and improvements have been completed during the past year.

RESULTS FOR CALENDAR YEARS

	1913	1912	1911	1910
Profits for the year	$1,255,954	$1,000,610	$1,019,392	$1,140,504
Balance brought forward	452,601	508,545	500,603	336,807

Victor-American Fuel Co.

In the fourth annual report of this company, for the year ending June 30, 1913, Vice-President W. J. Murray says in part:

The net income was $591,542. After providing for fixed charges and depreciation reserves, a balance of $257,107 (being $101,357 less than in 1911-12) was carried to credit of profit and loss. On Nov. 5, 1912, a dividend of 1½% on the capital stock for the six months ending June 30, 1912, was paid, and on June 3, 1913, a further 1½% for the half-year ending Dec. 30, 1912. After making allowances for these dividends and other minor adjustments, the credit balance in profit and loss account Jun 30, 1913, was $198,513. The decrease in tonnage of coal produced was 73,390 tons; in tonnage of coke, 10,981 tons.

The decrease in surplus income was brought about by a number of causes, mainly of a temporary character. On Apr. 1, 1912, an advance in wages to all mine employees of 10% was put into effect, and on Mar. 5, 1913, in Colorado, and Aug. 1, 1913, in New Mexico, an 8-hr. day was put into effect, causing a reduction of 20% in the hours the mines were operated daily without any corresponding reduction in wages. On most of our steam-coal contracts an equal increase in the price of coal was secured, but the price of domestic coals could only be increased gradually to meet this.

On June 18, 1912, an explosion of gas in the Hastings mine caused the death of twelve miners and a considerable property loss, and greatly curtailed the production of coal throughout the year and increased the cost of the smaller tonnage produced. Unusual expenditures in painting and repair of tenant houses, increase in taxes, payments for personal injuries and reduced dividends from the Western Stores Co. account for fully one-half of the decrease in surplus income.

The Stores Co. suffered a large loss in the volume of business transacted in an effort to check the growing evil of credit sales, but by the close of the year the business had resumed its normal proportions.

During the year there was a great scarcity of mine labor, resulting in a loss of tonnage and an abnormal expense in shipping men into the mining districts. This shortage of mine employees was general throughout the United States and was to some extent occasioned by the large number of Slavs, Greeks, Bulgarians, etc., who returned home during the Balkan War.

The New Mexico mines showed a material increase in earnings, confirming the expectations expressed in the last annual report.

RESULTS FOR YEARS ENDING JUNE 30

Short Tons	1912-13	1911-12	1910-11	1909-10

See This Waste Coal Dump?

It was made BEFORE the advent of The MASSCO Coal Washing Table and with the best Coal Jigs available.

THE Steam Shovel is now loading this Dump on cars for Re-treatment on MASSCO TABLES, the cleaned slack going direct to the coke ovens. Especially adapted for cleaning coal too fine for jigs. Capacity 5 to 8 tons per hour.

Send for descriptive Bulletin No. 28.

A Barsteel Gathering Locomotive
That Will Operate in a 29-Inch Clearance

Here is an illustration of a Baldwin-Westinghouse Barsteel electric gathering locomotive that operates successfully in a clearance of twenty-nine inches—36 inches was heretofore considered about the limit for locomotives.

Great care has been exercised in keeping the overall height to a minimum, as is shown in the general construction of the locomotive and the location of the reel.

There is not a projection above the top of the frame anywhere and ample room has been provided to permit the operator to crouch upon his seat.

The reel is driven by an independent motor contained inside the reel drum. This motor is in effect an electrical spring. It tends to wind the cable up and its turning force acts as a brake and keeps the cable taut when the locomotive enters the room and promptly takes up all slack when the locomotive returns.

With this type of reel there is easy access to the locomotive motors, because of its being located out of the way on the rear of the frame. The armature of the reel motor can be readily removed for inspection and overhauling.

Locomotives of this type have successfully solved the problem of gathering in very low rooms. Our specialists in mine haulage, who make a careful study of various mining problems will be glad to assist you in selecting the proper equipment for your mines.

Get in touch with them by writing to either company.

When the Cap Burns Blue

By Berton Braley

Written expressly for Coal Age

I

It's waiting, waiting, waiting,
Though you don't know where,
It's lurking 'round the corner
And you must take care,
It's deadly as the lightning
When it strikes at you,
And you want to take no chances
When the cap burns blue!

II

You cannot smell or see it,
Where it lies in wait
To wrap you in the mantle
Of its deadly hate;
Perhaps you'll never meet it
All your whole life through,
But you'd better hike for safety
When the cap burns blue!

III

It steals upon you softly
It breathes upon your lamp,
Which should give an indication
Of the presence of the damp.
So if you love your children,
And your good wife, too,
You'll try to make your exit
When the cap burns blue!

IV

There's a lot of little tombstones,
Which would not be there
If the fellows lying under
Just had taken care,
But they monkeyed 'round with danger,
As some men WILL do,
And they didn't pay attention
When the cap burned blue!

V

So all you greeny miners,
You just watch your step,
There's a need of sense in mining
And I'll put you hep;
You watch the roof above you,
And the coal dust, too,
And don't you play with firedamp
When the cap burns blue!

Ideas and Suggestions

Educating the Public

By Mine Inspector

SYNOPSIS—An attack on present socialistic tendencies, with arguments opposing the nationalization of mines.

In any enterprise, whether individual or corporate, labor and capital combine through their energy, skill and financial resources to supply a product for the public in a satisfactory manner.

If labor and capital estimate correctly the public's wishes, industry flourishes, and labor and capital find the maximum of employment. If, however, in supplying that which the public wishes, labor or capital is not satisfactorily employed, they must look to the public for redress.

In the early days of feudalism, much wrong existed and no one will say that the world's democratic movement has been without a rational end, but labor has been so insatiable that today we may say new enterprise is dead, because the spirit of economic adventure has been paralyzed by the uncertain outcome of the world-wide social unrest. Great Britain has been on the verge of civil war. The Caillaux affair was only an incident in the politics of that thriftiest of all nations, France. In our own affairs, the extent to which radicalism has gone can best be illustrated by the new conception of property as expressed by Secretary of Labor Wilson or by the changes already wrought in lines of business legality.

Dangerous Doctrines

Demagogues, parasites on the body politic, that prey upon the public, aided and abetted by their kind in our Congress and among the counselors of the nation, are to be found in every industrial community in the country, teaching the most insidious of all doctrines—that capital should not partake of the fruits of industry, for it does nothing toward the production of the nation's wealth; and that in the government ownership and operation of all industry lies the only solution of the problem. In their dangerous doctrines, they do not "appeal to reason."

Today the "Arteries of the Nation" are fighting for existence, not because of their inefficiency, as these same demagogues would have the public believe, for the railroads of this country are the grandest achievement in the science and art of transportation that the world has ever witnessed; but because the laborers of these great factors in the nation's prosperity have educated the public into believing that they are underpaid and overworked, notwithstanding that they are the highest paid railroad men in the world.

In their clamorings, these same teachers of the public do not "appeal to reason" and present for the public's consideration that the state-owned railroads of Prussia do not show a profit of six per cent., and these figures do not include a capital charge on the railway debt, or a fund for betterment, or the redemption of capital. Yet the state-owned railroads of Prussia are notorious for their inefficiency, red tape and their special tariffs.

Nor do these same counselors of the nation explain that the state-owned railroads of Austria are a constant drain on the tax payers, yielding only two to three per cent. and paying no taxes. Economists have noted that three conditions arise in the state-owned railroads: First, where they are profitable and the public treasury absorbs the profit, in which event the interests of the shippers and passengers are sacrificed to those of the government; second, where the roads are operated at a loss and the deficiency is made up by taxation, i.e., the interests of the taxpayers are sacrificed to those of the shippers and passengers; third, where all other interests are sacrificed to those of the employees, political considerations transcending those of transportation, a condition asserted to be in a varying degree an unavoidable attendant upon state ownership.

The connection between railroading and coal-mining is at once apparent when the fact is stated that sixty-five per cent. of the freight in this country is offered by the coal industry.

Nationalization of Mines

While the problems of the railroads seriously affect the coal industry, of more genuine concern is the crisis confronting England in the proposition presented by the Mining Federation for the Nationalization of Mines, wherein it is proposed to confiscate the mineral from the present owners. The same propagandists that educate the public in the United States have as a champion of the above proposition in England Councilor Chapman of the Northumberland Miners Association who would have the public believe that in the nationalization of mines: (1) Less waste of valuable coal would occur; (2) cheaper coal for the consumers would result; (3) conditions of employees would be improved, fatalities would be less, wages would be higher; and (4) profits from the operations would be greater; but Councilor Chapman does not "appeal to 'the' reason" of the public and submit for their consideration the results of state ownership of mineral and operation of mines in France, Germany, Belgium and Australia. As a matter of fact, none of the benefits claimed for the state management of mines by Councilor Chapman have been secured by the nations which have adopted it.

A striking example of the inefficiency of state ownership of mines, mentioned by Prof. Henry Louis, in an address before the Newcastle-upon-Tyne Economic Society, is that of the Wonthaggi mine owned by the Victoria Government. Prof. Louis states that this mine is without competition, but the profits from operations were only 10c. per ton and the mines were idle during the year 1912 for six weeks while the coal diggers struck to obtain the *average* wage rate of coal diggers throughout the country.

New Laws in Ohio

In the United States, the public is immediately concerned with the recommendations of the Ohio State Min-

ing Commission to the Governor of Ohio, dealing with the regulation of mines and the law enacted by the state legislature prescribing the basis upon which the miner shall be paid.

If the results of state ownership of mines are presented to the public in a clear and concise manner devoid of technicalities, even the most fatuous will not deny that the public would refuse to be mulcted of the heavy tax necessary to pay for the evils brought about by the state management of mines.

The problems confronting coal operators are not so much that of their relationship with labor, but rather that of their relations with the public. Today this relationship is strained and unfriendly, due to the envy and snarlings of the labor agitators who have misguided the public while the operators sit idly by. Let the publicity bureaus of the several coal operators' associations be publicity bureaus, and not bureaus of censorship from which only negative results may be expected. There is no doubt a genuine desire on the part of the public to be advised, and there is no greater work to which the operator might cheerfully contribute than that of cultivating the intellect of the public to which the rapid vaporings of the agitator do not appeal.

The Great Issue Today

The politicians would have the public believe that the great issue of today is that of the "Workingmen's Rights," but that with which we are really concerned is the public's rights, whether the principle of private property upon which our democracy stands shall hold.

At no time in the past have the communistic theories been so strongly before the public. At no time in the past has the public been so insistent that they are paying the bills. At no time in the past has the public so strongly appealed for relief from the political octopus whose tentacles are sucking its life blood at every pore. The common sense, fairness and self interest of the public have never been greater, for it has become apparent that the high cost of living is the price paid for following the teachings of the socialistic demagogues and political campaigners.

That the lesson to the public, as exemplified in the present hard times, should be allowed by the mine operators to pass unnoticed, is almost unbelievable.

An Ounce of Prevention versus a Pound of Cure

By Anthracite Engineer

Some time ago, I had occasion to go into one of Pennsylvania's largest coal mines, and while climbing a breast with the fireboss, we noticed two miners tamping their holes with a piece of steel. I remarked to the fireboss how dangerous and unlawful this practice was, and my suggestion brought forth the reply, "They've probably left their tamping stick in the gangway, and there is no use to say anything, for they'll use their steel again as soon as my back is turned."

In how many mines of the country is this same thing being duplicated day after day. In every catalog of high explosives, in the rules of practically every mining company, and in the state laws, it expressly implies that none but a wooden or soft-metal tamping stick should be used. Is this rule inserted merely to fill space? No! "There's a reason," as every mining man with any common sense knows. The number of deaths caused by the wilful violation of this simple rule will never be known, as there are rarely any witnesses left.

The Company Officials Are Responsible

Now, Mr. Foreman and Mr. Fireboss, it's up to you. You know that a steel tamping bar is used in violation of all rules and good practice; therefore, why do you allow it? Because the miner won't pay attention to you if you do tell him? That's not sufficient. A nurse girl leaves her charge, thinking he will not burn himself with the safety matches with which he is playing. He does burn himself, however, and morally, if not legally, the careless nurse is responsible. Now are you not in the same position as the nurse girl. "No," you say, "the men know better, and if they take a fool chance I'm not to blame." But you are. The men in your mine are employed by your company, and that company is to a greater or less extent responsible for anything that happens to those men.

Now whose business is it to see that those men do a good day's work? Your business. Then, is it not also your business to protect your company by not allowing the men to do anything which will be of danger to themselves or to the mine?

Fire the First Man Who Disobeys

What can be done if a man persists in using steel for a tamping bar? Why, fire him on the spot. You say, "Good miners are scarce." We believe you, but fire one or two and see if the others don't get in line. Oh, yes! —the Union. Well do you think any sane body of men could say much against your protecting the miners under you from their own carelessness?

But wait. Some weeks ago a man demonstrating dynamite, informed me that in the mines of one fairly large company he loaded over 800 holes and could not find a tamping stick more than half a dozen times. The foreman had ordered tamping bars, but someone with an eye toward making a hit with the "big boss" decided that this was a place to economize. Economy is a great thing, we all admit, but when carried to the extent of being "pound foolish and penny wise," it sometimes borders on being criminal.

There is an old adage, which says, "an ounce of prevention is worth a pound of cure." Now, we've spent thousands in hospitals and first-aid, and have our pound of cure; but why not apply the ounce of prevention first, as the cure can never bring back a life.

It is the conviction of James Lomax that a systematic microscopical survey of the various coals will lead to results of the utmost value in (1) determining the geological age; (2) the identification and correlation of seams, and (3) the various constituents therein and their effect on the causes of spontaneous combustion and inflammable dust.

When testing for gas with a lamp, the length of the "cap" with a given percentage of gas is not necessarily unalterable. As lately pointed out, with the very best intentions in the world and with the best management, the oil employed in the lamps at the colliery may vary; the wicks may vary; the method of trimming the lamp, both in the lamp room and when making the test underground, may vary; there may be more dust about the lamp at one time than another. These and other causes may easily affect the "cap."

The Amherst Company's Plant in West Virginia

By W. M. Judd*

SYNOPSIS—Description of a plant equipped with some elaborate retarding conveyors and also an effective screening arrangement. Two seams are mined about 200 ft. vertically apart.

During the past year the Amherst Coal Co. has completed and put in operation a new plant at Amherst, Logan County, W. Va. The lease upon which the company is operating is situated about five miles from the Guyandotte River on Buffalo Creek and is reached by the Buffalo Creek branch of the Chesapeake & Ohio R.R. Its lease comprises about 1300 acres and is underlaid by at least three merchantable seams, as follows:

1. The "Eagle," which does not outcrop within the limits of the lease and is not being developed at the present, although the company has recently acquired the adjoining lease upon which the "Eagle" seam is being worked. The tipple on this latter lease is about half a mile downstream from the Amherst Coal Co. tipple. The elevation of the bottom of coal at the pit mouth is 880 and the coal is 6 to 7 ft. thick at the faces of headings. Eventually all three seams will be operated from drift mines under the Amherst lease.

2. The "Island Creek," outcrops almost 200 ft. above the railroad at an elevation of 1092 ft. above sea level. There are about 1000 acres of this seam upon the lease, averaging approximately 5 ft. in thickness. This is the seam in which the pioneer developments of the United States Coal & Oil Co., at Holden, W. Va., were made in 1903, and which has established the trade name of "Island Creek Coal," on account of its fine quality for steam and domestic service.

3. The "Winifrede" outcropping at an elevation 1355 ft., underlays about 700 acres and averages about 9 ft. thick.

Amherst is typical in many ways of the small mining settlements that are being developed in Logan County as rapidly as the railroads can provide transportation for the output of the mines. A slight widening of the narrow valley is occupied by the tipple, railroad tracks and a portion of the town, while perforce many of the miners' houses must be placed on the side of the steep foot hills.

The Tipple and Retarding Conveyor

As has been previously stated, the Island Creek seam outcrops about 200 ft. above the railroad. The run-of-mine coal is brought to the tipple by a retarding conveyor 420 ft. long, having a maximum slope of 30 deg. from the horizontal.

View of Power Plant, Tipple and Part of Town

The headhouse, located directly in front of the pit mouth of the loaded-car haulage heading, contains the hopper bin into which the mine cars are emptied by a kick-back dump. The coal is delivered from the hopper bin to the retarding conveyor by an apron-type feeder, driven by the same motor that operates the retarding conveyor. Between the feeder and conveyor the coal passes over a short section of bar screen. The fine coal is thus deposited on the conveyor in advance of the lump. The section of the conveyor directly under the screen is horizontal, passing thence over a vertical curve to the 30-deg. slope section. The lump coal coming to rest on the bed of fine coal never shows any tendency to roll when it reaches the steep section.

The retarding conveyor, of the double-beaded pan type, is driven by a motor located in the headhouse. Maxi-

*Engineer, the W. G. Wilkins Co., Westinghouse Bldg., Pittsburgh, Penn.

mum power is required when the conveyor is running empty, and when it is running full, the motor becomes a generator and throws power back into the line. The conveyor traveling 60 ft. per min., has a capacity of 200 tons of run-of-mine coal per hour.

Screens and Gravity Plane

The conveyor delivers the coal over a chute to the shaking screens. The screens are in two sections, driven by eccentrics placed 90 in. apart on the same shaft, which latter is driven by a belt from a motor. The upper screen is 4 ft. long and has bars spaced ¾ in. The fine coal passing through this bar screen is received by a small drop-bottom car for delivery to the boiler house. The remaining portion of the upper screen is a perforated steel plate, taking out all coal 1¼ in. in size and under. A hopper bin receives the combined nut and slack coal for loading on the first railroad track.

The screening surface of the lower screen is a stepped-steel plate with perforations 3x10 in. The egg coal pass-

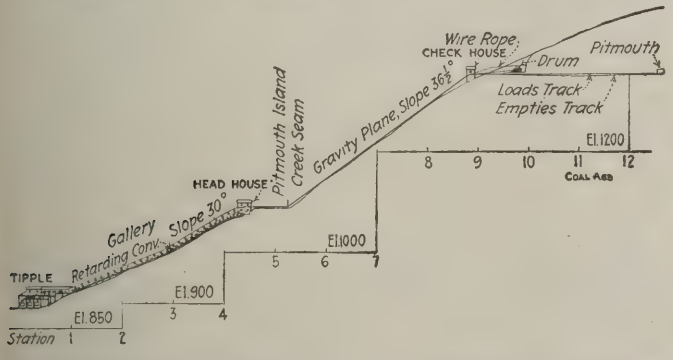

Diagram Showing Method of Handling Coal from Pit Mouth to Tipple

ing through the perforations is received by a hopper bin over the second railroad track. The lump coal passing over the screens is carried by a radial chute with adjustable apron for loading cars endwise on the third railroad track. A retarding gate in the radial chute enables the car loader to control the flow of coal, so that there is a minimum breakage of lumps in the car. The resultant egg and lump coal produced by this screening equipment has proved highly satisfactory to the trade. The retarding conveyor and tipple equipment was furnished and installed by the Pittsburgh Coal Washer Co.

The analysis and physical characteristics of the Winifrede and Island Creek seams are remarkably similar at this point, so that there is no necessity for the separation of the two coals in loading. The mine cars from the upper seam are lowered over a gravity plane and the coal dumped into the same hopper with that from the Island Creek seam. The plane is 450 ft. long between knuckles and has an average slope of 37 deg. from the horizontal. The plane is operated by a drum 8 ft. in diameter, supported by a heavy timber framework anchored into the rock about 90 ft. back of the knuckle. There is an outside tramroad about 375 ft. between the head of the incline and the pit mouth.

Methods of Mining and Power Plant

In both seams the headings and rooms are driven practically on, or at right angles to the cleavage of the coal and the main headings in the upper seam are located vertically over the main headings of the lower seam. The development of the upper seam will be kept well in advance of the lower, so that the mining of the upper seam will not be affected by rib-drawing in the lower.

The power house is a stone building, containing one battery of boilers, one direct-connected, engine-driven, 250-volt, direct-current generating unit, water-supply and boiler-feed pumps and feed-water heater. Sufficient space for the duplication of the power plant has also been provided.

Views of the power plant, retarding conveyor, a portion of the town and the gravity plane from the upper seam, are shown in the accompanying halftones. The W. G. Wilkins Co., of Pittsburgh, were the engineers for

Side View of Retarding Conveyor

the Amherst Coal Co., and all construction work was under the direct charge of their resident engineer at Logan. All the work was personally supervised by J. E. Schweitzer, general manager of the Amherst Coal Co., to whose efficient management is due the early date at which the entire plant was put upon a successful operating basis.

BY THE WAY

Precaution is better than repentance.

Do not wade where you see no bottom.

Some men change their principles oftener than their shirt.

Modesty, like a diver, gathers pearls by keeping his head low.

Promises may make friends, but 'tis performance keeps them.

Overcasts and Stoppings in Mines

By A. W. Hesse*

SYNOPSIS—Terra-cotta building blocks are now in satisfactory use for the construction of stoppings and for overcast walls. They are 40 to 50 per cent. cheaper than concrete walls and stoppings, though about equally more expensive than wood. The roofs of overcasts have been made successfully of plastered expanded-metal lath and it is probable that stoppings of similar material would give equal satisfaction.

In an article published in Coal Age (Vol. II, No. 6, Aug. 10, 1912), the use of terra-cotta building blocks was advocated for stoppings and overcasts. It was also suggested that expanded metal or wire mesh be used in place of scrap-iron pipe and steel mine rails when using concrete for such work, especially for the tops of overcasts.

Since that time the terra-cotta blocks have proven beyond a doubt their usefulness in a mine, as well as for the

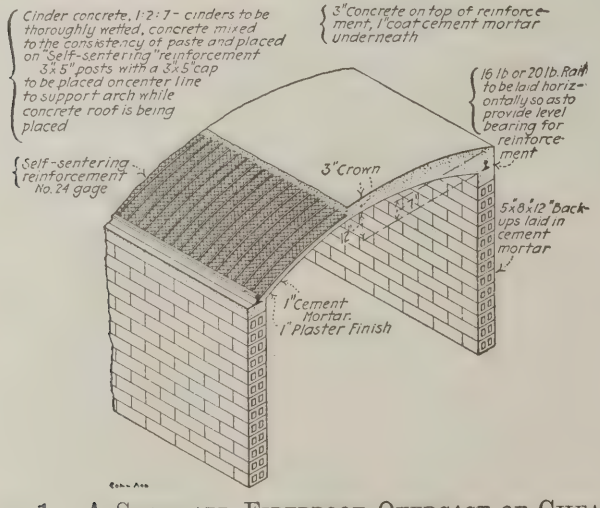

Fig. 1. A Standard Fireproof Overcast of Cheap and Permanent Design

purposes to which they are put outside. Not only have they been used economically for stoppings along the main air courses, but they are now being adopted successfully for the walls of overcasts. It appears also that scrap iron is to be displaced by a reinforcement which gives a concrete structure not only more artistic but more economical and more quickly erected.

Terra-Cotta Stoppings 40 Per Cent. Cheaper Than Concrete

The Consolidation Coal Co., as a preventative of fire at the same time as a safety-first measure, decided to eliminate wood stoppings and wood overcasts where practicable and to allow no more new overcasts anywhere to be constructed of combustible material, the same to apply to permanent stoppings along main entries.

The most natural step was to use the cinders from the boiler house at the mine and to build these structures of concrete. However, investigation proved that too much money was being spent for these improvements. The stoppings were reduced to a thickness of 4 in., but the cost still appeared too large.

*Assistant chief engineer, The Consolidation Coal Co., Fairmont, W. Va.

The terra-cotta blocks were first used for stoppings and their success was readily apparent. As the 4-in. cinder-concrete stopping had proven stable, a hollow block of 4-in. width was at first advocated; but the 5x8x12-in. block was finally adopted and has been used as a standard ever since.

On main entries where the stoppings are intended to remain for a considerable length of time they are bonded with a mortar composed of one part cement to two parts sand. On room headings where these stoppings have been built, lime was used in place of the cement, this making it possible to tear down the stopping when desired, without destroying the tile.

Sufficient cost data have been obtained on the construction of this type of stopping at the mines using this material to show a saving of from 40 to 50 per cent. in every instance as against the use of concrete. The cost compared to wood stoppings for room headings shows about the same difference in favor of the wood. It was thought that by the recovery of the blocks and their reuse this difference could be more than offset; but accurate costs kept on this work shows that it would be necessary to

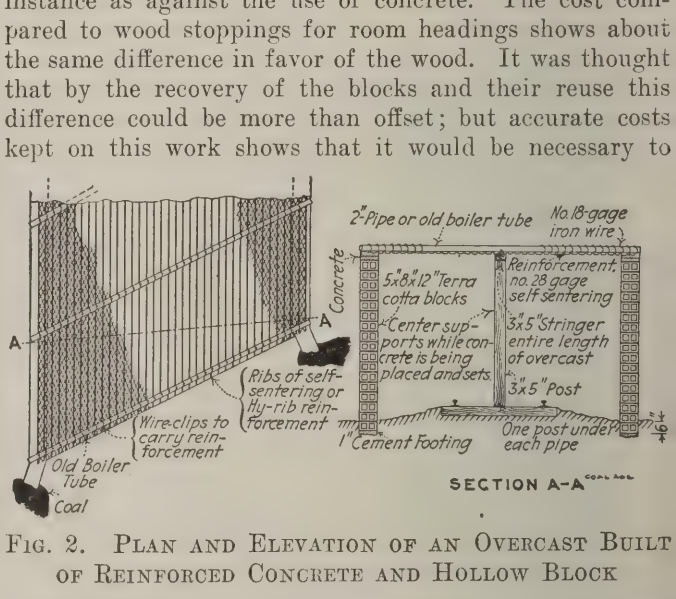

Fig. 2. Plan and Elevation of an Overcast Built of Reinforced Concrete and Hollow Block

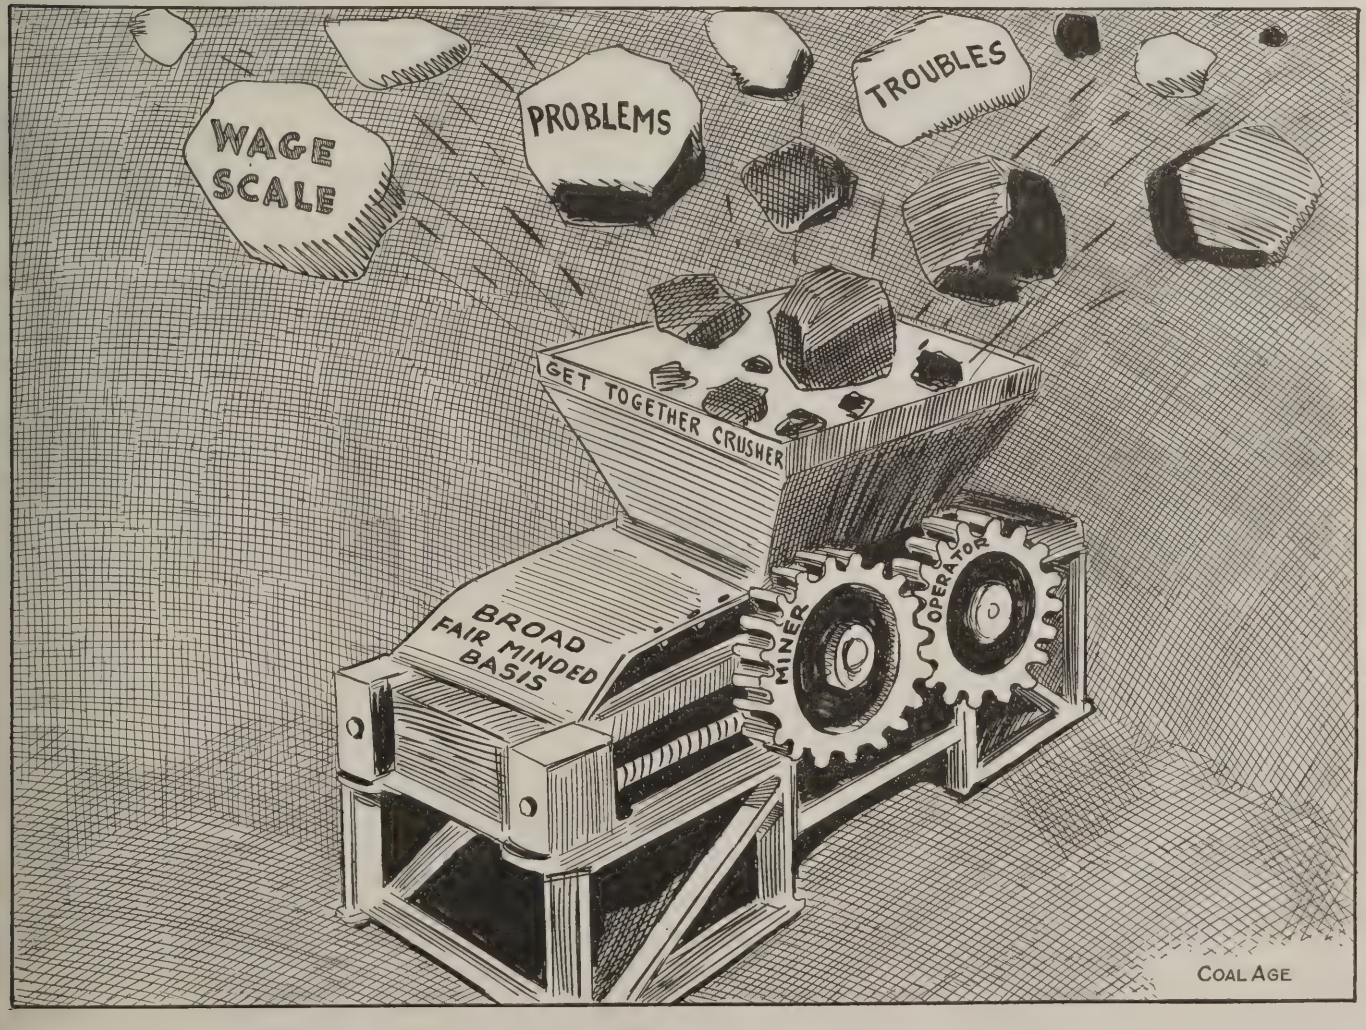
recover these blocks several times over to do this. Therefore, it is not advisable to use the blocks for temporary structures unless for other reasons than economy.

The crosscuts in the mines of the Fairmont Region run about 10 to 12 ft. wide and 7 to 8 ft. high, and average about 80 sq.ft. in area. It has been found that two men will construct three or four stoppings per day, providing the material is placed ready for their use.

Brattices Made as Screens of Lath Coated with Cement or Lime Mortar

We might be able to reduce the cost of stoppings further by the use of "Self-sentering," "Hy-Rib," or "Rib-Lath," plastering these with a cement mortar an inch or two thick. A stopping made with any of these materials properly placed, should carry as much as, or more pressure than, the ordinary wood stopping. The plan of erection would be simple, consisting of trenching the ribs, roof and bottom an inch or two, slipping the adopted metal in place and plastering with cement or lime mortar, the material depending upon the desired life of the stopping. Price and the strength which could be secured should govern the selection of the reinforcement. A heaving of the bottom would in all probability be cut by

the stopping, since heaving is caused by the swelling of the fireclay, this material at the same time softening markedly. If the pressure comes from the top or roof there might be much deflection in the stopping without doing it any material injury, besides it could be as easily repaired as the wood stopping in case of sufficient pressure to cause cracks in the plaster.



Overcasts with Air Crossing of Expanded-Metal Lath Plastered with Cement Mortar
